PRIMULA MALACOIDES: *A Dorset Gardener.* The note on p. 180 will furnish the information you ask.

TODEA SUPERBA: *O. D. K.* This plant is seldom propagated in this country; strong stems are usually imported from New Zealand for supplying offsets. It is seldom that the old stems produce any offshoots, and the only other method of increase is to raise the plants from spores, which are, as a rule, produced in abundance on strong, healthy specimens. The spores should be sown as soon as they ripen or become brown, and should be afforded the same conditions with regard to shade and atmospheric moisture as the parent plant. The spores are best sown on a piece of soft sandstone or in a small pot of carefully sterilised compost consisting for the most part of peat and sand. In either case the pot or sandstone should be stood in a saucer of water, in order to keep the compost moist, thus obviating overhead watering. On no account should the soil be watered from above, as the minute spores would be washed into the soil, and they would then fail to germinate. After sowing the spores fill the saucers with water, and add water whenever necessary. The spores germinate and produce dark green, kidney-shaped prothalli, and when this stage is reached they may be watered overhead. Later on the young plants may be pricked off into small pots and afforded exactly the same treatment as the parents. At no period should this plant be exposed to the sun; it should be carefully shaded at all times.

TOMATOS: *C. A. B.* Send specimens of the affected seedlings for examination.

TREE SURGERY: *A. C. M.* Remove all, or as much as possible, of the decayed wood, then wash the surface with a strong solution of carbolic acid, and after this has become quite dry smear the surface with coal tar. This antiseptic treatment is intended to destroy parasitic fungi and arrest the decaying process. The hole should then be filled up and made watertight. If it be small the best "stopping" is formed of a piece of Oak made to fit, but large holes should be filled with cement. In either case a final coating of tar should be given. Except when the hole is very large, a new layer of bark will grow over the cavity when treated in the way described.

THE DATE PALM.*

MR. POPENOE has written a fascinating book on the Date Palm—"The Dadel, a Tree Unknown to Us" of John Ogilby, the seventeenth century traveller.

The book is fascinating because it brings the superstitions of remote antiquity into friendly communion with the latest word of the strenuous scientific commercialism which is to Europeans such an impressive feature of modern American life. Mr. Popenoe demonstrates that the hard-bitten man of affairs, bent on making the Date one of the chief fruit crops of the United States, may in proper time and place take a kindly cognisance of the curious legends and bizarre practices which have grown up in the countless centuries during which the Date Palm has been in cultivation. It is so easy to treat in diffuse, sentimental and patronising digressions of the historical aspect of such a subject as the "Dadel": it is extraordinarily difficult to write a clear, businesslike, practical and continuous narrative which contains, without detriment to its directness, as much of the past as of the present phase of Date cultivation. This difficulty Mr. Popenoe has overcome, and it is evident that he has overcome it because he is at once a practical man and an artist. Mr. Popenoe is a firm believer in the commercial promise of Date cultivation in the United States. He holds that in California and Arizona the cultivation of the Date has already proved a success, and is of opinion that the near future will see an extension of commercial Date-growing into California and Texas, as well as in Mexico.

* *Date Growing in the Old World and the New.* By Paul P. Popenoe. Published by the West India Gardens, Altadena, California. 2 dollars 16 cents.

With that American thoroughness which is the envy and admiration of the easier-going Englishman, Mr. Popenoe has pursued his investigations not only at home but in the chief Date-growing countries of the world. His journeys have extended from the North African littoral and deserts through Turkey and Persia into India. He observed in the last-named country that "there has been during the last half-century a small but continuous effort to establish the Date Palm on a large scale"; and he holds out some hope that in some localities these efforts may meet ultimately with success. Mr. Popenoe's enthusiasm for Phoenix dactylifera is almost equal to that of Mohammed, who proclaimed that "there is among the trees one tree which is blessed as is the Muslim among men; it is the Palm. Honour your uncle, the Palm: I call him your uncle because he was created from the earth left over after the

the Date Palm. Apart from this need for water the tree is not exacting. It grows and is fruitful in light and heavy soils, responds well to manuring with dung and humus, and in the adult stage withstands winter frosts; though it must be protected from wind. It is found advisable, however, to protect the ripening fruit (see Fig. 89).

Propagation may be effected by seed or by offsets (see Fig. 88); but, as the author insists, the latter mode of propagation is by far the better, and this for two reasons. First, the offset from a female Palm is of course female, whereas, of seedlings, about half are male and half are female, and hence large numbers of useless male plants must be grown until they declare their sex at flowering time, when those not required as pollen-bearers must be discarded. Second, as is the case with all long cultivated plants, Date Palms are extremely variable, and hence the offspring

FIG. 88.—CULTIVATION OF DATE PALMS: SETTING OUT OFFSHOOTS.

(Quarantine regulations in the United States require that they be planted in nursery rows, and kept there for one year.)

creation of Adam. . . . The Palm resembles man by its erect position and its height, by its separation into two sexes and by its necessity for the pollination of the female. If its head is cut off it dies. . . . Is it not the same with man! If its leaves are cut off it cannot grow others in the same place; no more can man if he lose his members. It is covered with a fibre analogous to the hair of man." To those only familiar with the Date Palm in pictures or pots the most striking point of Mr. Popenoe's account of its "cultural requirements" is the need of the Date Palm for large and continuous supplies of water. It grows and fruits best (see figs. 90 and 91) when well and even constantly irrigated. Thus in Persia the immense plantations around Busreh are irrigated naturally and copiously every twelve hours throughout the year. Indeed, the author maintains that irrigation is the principal item in the cultivation of

of a choice kind are anything but true to the characters of the parents. The work of breeding pedigree races, which has been undertaken in America, will without doubt meet ultimately with success; but in the meantime offsets from fine forms should be used, because, as is the case generally with asexually produced plants, they are true to character.

That the Date Palm fails to set seed unless the female is pollinated was known centuries before the present era, and bas-reliefs on Assyrian monuments illustrate the operation of pollination. Mohammed never showed his astute genius better than in retrieving the great error into which he fell when he forbade the artificial pollination of the Date Palm on the ground that it is an unnatural practice. The obedient followers of the prophet abstained and the harvest was barren. As Mr. Popenoe puts it, "an indignation meeting was held," and as a result the Prophet announced, "You

are weak in spiritual knowledge, but are worldly-wise; therefore in future I will confine myself to the government of your spiritual welfare, and let you manage the affairs of this world to suit yourselves"—a pronunciamento bound to be acceptable to a race of people with commercial instincts.

To secure crops, artificial pollination must be, and is, practised both in the Orient and in Occidental countries—wind pollination is too uncertain and insufficient. The male inflorescence with its spathe is detached as soon as it is mature, the spathe is slit open and the sprigs of male flowers are removed and placed in a basket for twenty-four hours. The cultivator climbs a tree on which the female flowers have burst their spathe and inserts several clusters of males among the females, and ties them in their place. If kept dry the pollen lasts a long time, and it is interesting to observe that it is cus-

into the methods devised for ripening the fruit artificially, although these are matters which to our readers in sub-tropical countries are of considerable interest; but we may conclude our review by recommending horticulturists generally to read this entertaining and beautifully illustrated work, for we are assured that whether they grow Dates or not it will bring them both pleasure and profit.

GARDENS FOR THE POOR IN FRANCE, GERMANY, ENGLAND AND AMERICA.

(Concluded from page 179.)

SMALL gardening for the poor is on a different basis in Germany. In consequence, doubtless, of the brilliant success attending the French private movement, it has come to pass in a number of German towns during the last three or

imitated in Königsberg, where the Poor Relief Board prepared an acre or so of municipal land for agriculture and kitchen-gardening, and in May, 1910, divided it into allotments, each of from 80 to 600 square yards. The first experiment was made with 25 married or unmarried recipients of poor relief, a preference being given to widows with children and those who though infirm were not incapable of garden work. The under-letting of allotments is prohibited. Larger tracts of land are to be prepared for the same purpose. Frankfort and Strassburg have also recently come to follow the good example of Posen. Not long ago the town council of Dresden decided to devote provisionally 4,800 square yards, together with the necessary seeds, to the same purpose. A rapid advance in this new small gardening movement will doubtless soon be made in consequence of the following decision of the Third International Congress for Workmen's Gardens (Brussels, autumn, 1910)*:—

"Taking into consideration the fact that the poor relief burdens weighing upon municipalities and charitable institutions are not infrequently to be traced to drink, consumption and the consequent corporeal and moral distress, and that family gardens form one of the most efficient weapons against this distress, the congress expresses the request that municipalities and poor relief boards shall promote such gardens and assign them to large families, instead of giving cash assistance. The State and municipalities should be bound to lease to garden societies at moderate rates a part of their land suitable for cultivation."

The same congress also requested the speedy enactment of laws that, like those in France, should render family gardens not subject to mortgage or distraint.

A novel kind of experiment in plot-gardening for unemployed workmen is being successfully carried on in a wretchedly poor part of the East End of London. In 1906 the West Ham Unemployed Aid Society obtained permission to use gratuitously three acres of the Gas Light and Coke Company's vacant land in Canning Town for the purpose of granting garden plots to temporarily unemployed workmen. In 1907 two acres were added. Two years later the Mansfield House Settlement took the concern over, and were given the free use of the whole of the Company's vacant land—30 acres. This area is at present divided into 340 plots. The holders have to buy their own seeds, or else they have to repay the price out of the sale of produce. Only vegetables are grown, the vicinity of the gasworks having proved detrimental to flowers. The average annual yield amounts to about £5 per plot. In 1912 the management of the Settlement asked for a voluntary yearly contribution of 2s., and most of the holders cheerfully responded. Up to then nothing had ever been paid in the way of rent. This kind of gardening gives some work to the unemployed, and enables them to earn at least part of their living.

* The first two were held in 1903 and 1906.

FIG. 89.—PROTECTING THE RIPENING DATES.

tomary in some districts to keep pollen from year to year. Trials made at the Mecca Experiment Station have shown that pollen may be kept for seven years and retain its power of fertilisation. Equally interesting is the statement that fertilisation may be effected by the pollen of other species of Phoenix, e.g., *P. canariensis*, and with other genera of Palms such as *Washingtonia filifera* and the Mediterranean dwarf Palm, *Chamerops humilis*. Growers are advised to establish three or four males for each hundred females. An old statement by Schweinfurth (in 1901) that the qualities of the fruit are influenced by the pollen used for fertilisation is said to be borne out by recent experiments made by Bruce Drummond in California. This statement is by no means in disaccord with modern views on fertilisation, and might well be tested in fruits other than the Date. We need not follow the author in his estimates of the profit of Date-growing, nor

four years that the municipal authorities themselves have assigned land for market gardening, instead of cash, to those entitled to relief. This was first done in April, 1909, at Posen. In the suburb Gurtsein there were first rented about 1,800 square yards, which were assigned to seven large families for cultivation. A few loads of manure were given them free, and the seeds they bought themselves. The crops not only supplied the said families with all their vegetables during the summer and autumn, but also yielded a small store for the winter. They drew much more money from the garden than would have been given them in cash, and the town fared equally well, for with a total expenditure of 17 marks (rent) from 70 to 100 marks had been saved in cash assistance. The new arrangement is of even greater value as regards health and education. Naturally in Posen there has been a considerable extension of the successful experiment. It was

This principle of putting waste land to philanthropic use might be called a "Columbus egg" in its simplicity, inexpensiveness and usefulness. No wonder it is beginning to be acted upon on a larger scale in England and America. Recently I received the fifteenth annual report of the Philadelphia Vacant Lots Association. From it I gather that "the land is prepared, and fertilisers with seeds are supplied annually, at a cost of \$5 to the Association for each plot." No rent is charged, but every holder is required to contribute, for what is supplied to him, \$1 the first season, \$2 the second, and so on, so that a family which

funds, it has to be content at present. It obtains the loan of this land from the owners, letting it in 500 plots to needy men or women of the working classes. It is noteworthy that every sovereign spent by the V.L.C.S. means five times this amount in vegetables for the plot holders. "Recognising the value of the aid they receive, and aware of the fact that the society is not adequately supported by the public," most of the holders lately volunteered to contribute to the management and seed fund. Some offered to pay as much as 15s. a year, stating that they "would much prefer doing so to receiving continuous gra-

THE BULB GARDEN.

JAPANESE LILIES.

The rapid rise in popularity of Japanese bulbs of *Lilium longiflorum grandiflorum* is one of the most noteworthy features of present-day gardening. It is the more remarkable in that until about thirty years ago but little attention was paid in Japan itself to the cultivation of *L. longiflorum*. The flower was left to waste its sweetness on the desert air—or rather to grow wild among the bushes of Oshima, the island which lies about 200 miles south of the town of Kagoshima.

It was only about twenty-five years ago that bulbs of *Lilium longiflorum* were brought from Oshima to Yokohama, where they were grown,

FIG. 90.—DATE PALM IN FRUIT.
(A recent frost had destroyed some of the leaves.)

FIG. 91.—HARVESTING DATES:
Taking the crop of an unusually tall Palm at Elche, Spain.

continues to cultivate a garden pays in the fifth season the full five dollars.

Encouraged by the good results obtained in the States, the late Mr. Joseph Fels, the well-known land reformer, called into life a Vacant Land Cultivation Society for London, in 1908, which, according to its fourth annual report, is doing splendid work—materially as well as educationally. An official return of the L.C.C. puts the metropolitan acreage of unused vacant land at 14,000. Part of it would be too expensive to prepare for plot gardening, but there is ample that would need comparatively small outlay. The society could, if it had the money, very well manage ten times as much as the 60 acres with which, owing to lack of

tuitous aid." Recently a branch society was founded in Birmingham. The report rightly expresses a desire for "substantial recognition" of its work from public bodies to enable it to effect a large extension of its acreage. I hope that not only public bodies but some public-spirited persons of means among my readers will do something substantial for the meritorious work of the V.L.C.S., or for establishing similar agencies in other large towns. There are few ways in which money may be spent to better and more lasting good purpose; for to this discriminating form of help the Pauline aphorism certainly applies: "Faith, Hope and Charity, these three; but the greatest of these is Charity." *Leopold Katscher.*

and obtained high prices. In those early days the bulbs fetched about ten times their present price. The imported bulbs flourished in Japan and, after the manner of introduced plants generally, began to show a certain amount of variation. It was discovered, however, that the Lily is a capricious plant and soon tires of any one soil, and if not given the change for which it craves degenerates year by year. In spite of this discovery not a few growers in Japan continue to grow the bulbs in the same ground, and hence arise the complaints so often heard in England as to the quality of the bulbs imported into this country. In consequence of the deterioration of the bulbs the reduction of prices pressed heavily on the local growers and on the exporters. In these difficult times not a few Japanese growers endeavour to speed up or cheapen production of bulbs of *L. longiflorum* by planting in shallow soil, with the result that

though the size of the bulbs may have been increased the quality was undoubtedly reduced.

The custom of some dealers of collecting indiscriminately bulbs grown by large numbers of small men contributed also to a lowering of quality, especially in the winter-flowering variety of longiflorum. The form known as *L. l. formosanum* is held by some to be a separate variety obtained from Formosa; but, in point of fact, this form, put on the market about nine years ago, is obtained from Oshima, the home of *L. longiflorum*.

The reason for the greater vigour of the formosanums is that they are grown in their native habitat, and, when proper care is taken in selection, their growth and time of flowering are perfectly uniform.

The giganteum variety which is amenable to pot cultivation is distinct from that known as formosum giganteum. Now that I have grown the latter for many years in its native home thoroughly satisfactory bulbs are obtainable. It has the further great advantage that it can be shipped two months earlier than the ordinary giganteum, and so is ready earlier for winter forcing. *Sei Miyake*.

CYCLAMEN PSEUD-IBERICUM.

Cyclamen pseud-ibericum (see fig. 92) is the finest of all the hardy members of the genus. The species was described in 1901 by Hildebrand from plants growing in the nursery of Messrs. Van Tubergen, of Haarlem, but its origin was not given. The leaves, like those of *C. ibericum*, are marbled with a zone of white; but instead of being entire, the cartilaginous margin is crenulate, while the under sides are a ruddy-purple colour. The rich rose-coloured flowers with the faintest tinge of purple are borne well above the foliage on stems 4 inches to 5 inches long. The segments are 1 inch long and more than half-an-inch wide; each has a dark-purple blotch at the base, whilst the edge of the ring is white. The first flowers are produced early in February, and the plant continues in bloom through the month of March. *Cyclamen pseud-ibericum* is quite as hardy and as easy to grow as *C. coum* and *C. ibericum*, but is a great advance on either in the size of its flowers, which suggests that it is a hybrid rather than a true species. *W. I.*

THE ROSARY.

PLANTING, PRUNING AND MANURING.

PLANTING may still be carried on with every prospect of a successful display. It is well to plant some Roses rather late each spring, as they will thus provide blossom a little later than the general crop. Retarded plants should be procured if possible.

Upon heavy land it is best not to dig or trench too much in advance of planting. If, however, the land does not require trenching, it is a good plan to throw it up in ridges. In a very short time it will become level and be in good condition for planting. Very short manure mixed with the soil as it is levelled will assist in keeping it in condition, and will be beneficial to the plants. Roses should be pruned back hard immediately after planting. It is essential to water them at this time of year, not only as soon as they are planted, but once or twice afterwards at intervals of a few days.

Mulching in spring is a mistake, as it tends to keep the roots cold. Leave the surface soil rather rough, and see that it does not become too consolidated.

Old pot Roses which have been discarded from the forcing house, if healthy at the root, may be planted out early next month, and will then make useful plants for cut-flower purposes. Instead of pruning such plants bend them over, so as to induce basal growths. Such plants will develop well if carefully planted and given a little bone flour at the beginning.

Hedges of Rambler Roses should be planted

wherever opportunity offers, or in line down the kitchen garden. They furnish most useful sprays for table decoration, and the plants quickly establish themselves. The Multiflora tribe may be kept pruned quite low if necessary, and will blossom to the ground: the long growths should be tied out in a fan shape. The Wichuraianas not only provide handsome trails of blossom, but are worth growing for the decorative value of their foliage. It is becoming the fashion now to use Rose foliage only when decorating a table with Roses. This is right, and it is a good thing that the National Rose Society stipulates that only Rose foliage shall be used by competitors in their decorative classes.

The mildness of the winter has shown the wonderful beauty of the Wichuraiana foliage. Edmund Proust has been perfectly evergreen, and so also has American Pillar. We shall soon be using this latter Rose instead of Ivy for many of our outdoor effects.

As to pruning, much doubt still exists in the minds of amateurs as to methods.

Unquestionably the correct practice is to prune plants hard the first season, whether bush,

prune hard in the spring. If this cannot be done, then prune severely, and peg down the young growths when they are firm enough. Some of the more pliant shoots produced early last summer may be retained full length and tied over in April.

Wild Roses and all the briars are left practically unpruned; so are also the little Scotch Roses.

In all pruning one should endeavour to picture what the plant will be like in June and July. If growths are too numerous, reduce their number rather than their length, so that all foliage may have an opportunity to obtain air and sunshine.

If manure was dug in last autumn established Roses may be dressed with some bone flour now. Good, well-rotted manure may still be applied, but let it be lightly forked under the soil at once. If the beds or borders allow of it, first lightly fork up the surface, and then lay on the manure, covering this with some fibrous soil. Roses produce roots very near the surface, so that careless forking may do a great deal of harm. They are sometimes benefited by scooping away the soil around each plant and filling

FIG. 92.—CYCLAMEN PSEUD-IBERICUM.

[Photograph by W. Irving.]

standard, or climbing plants—i.e., within 4 or 5 inches of the base in the majority of cases. Vigorous growers, such as Juliet and Hugh Dickson, and also climbers, should be pruned to within about 12 inches of the ground. The Wichuraiana group forms an exception. These plants possess such a natural tendency to throw up basal growths that one may safely retain nearly the full length of two or three growths per plant. Weeping Roses of this group should not be pruned the first year until after the flowering time; then cut away some of the growths quite to their base.

Prune established Roses according to their vigour. Those making very strong shoots may be cut back less than the varieties of less vigour. Old wood should be freely discarded after the second year. This is best done in autumn in the case of the hybrid perpetuals. Free-growing Roses of the type of Margaret Dickson, Chio, Ulrich Brunner, and Hugh Dickson may have their ripened one-year-old wood retained for some 2 feet in length; they are thus more likely to blossom freely than if severely pruned. Frau Karl Druschki is sometimes a difficult Rose to manage. A good plan is to lift the plants in autumn and replant at once; then

up the cavity with cow manure, which may be covered with some of the soil.

If there are any old bush Roses which are not required, they may be cut down to the ground and the new growths that will spring from the base may be budded with good, popular kinds.

Several of our modern Roses make such strong, upright growths that they could be readily converted into standards by retaining one such growth some 5 or 6 feet long and cutting away all other shoots. Juliet is such an one. Coronation, the beautiful new H.P. of Messrs. Hugh Dickson, is another. In Belfast several standards of this Rose have been produced in the manner indicated. Some of the lovely Penzance briars treated like this would make interesting objects.

All exhibitors should plant out a few dwarf briar stocks annually, so as to be able to bud some of the varieties that yield their best upon "maiden" or yearling plants. Roses such as A. K. Williams, Alfred Colomb, Horace Vernet, and Marquise Litta, are never so good from a cut-back plant as from a maiden. Most of our eminent amateur exhibitors have several hundred stocks every year.

The present is a good time to plant out such stocks. Plant them upon good, rich, deeply-dug land, in rows 2½ to 3 feet apart, and the stocks about 8 inches apart in the rows. Many of the Teas and Hybrid Teas yield superior blooms from half-standard or standard briars the first year after budding, so that if any briars have been planted they should be reserved for such Roses. *Experience.*

NOTICES OF BOOKS.

MY GARDEN IN SPRING.*

ANYONE who knows Mr. Bowles and the catholicity of his taste in gardening will find that this account of his garden in spring is exactly the kind of book that he would have expected it to be, for it deals with nearly every class of spring-flowering plant that can be grown in English gardens.

The author is one of those lucky gardeners who are also men of leisure, and who are consequently able to rush off to Mr. Farrer's garden at Ingleborough when a *Galanthus Elwesii* has "poculiformed itself," and to Bitton when a note from Canon Ellacombe announces the arrival in his garden of a double-flowered form of *Anemone blanda*. Few gardeners, and least of all Canon Ellacombe, could refrain from being generous to a fellow enthusiast who had made a special journey to see his latest new treasure, and so it comes about that many interesting and rare plants find their way to Mr. Bowles' garden while they are yet unknown to the majority of gardeners.

Another result of Mr. Bowles' happy position is that he has the time to be his own gardener, and has thereby gained that first-hand knowledge of plants without which any writer on horticultural subjects is only too apt to be neither interesting nor informing.

The outstanding feature that will strike the reader is Mr. Bowles' passion for, and extraordinary knowledge of, the rare and freakish forms of well-known garden plants. He confesses that it gives him "more pleasure to have got together the three distinct forms—grey-leaved, golden and major—of *Sedum spathulatum*, and to make them share a flat-topped rock with at least six other species of *Sedum*, than to have the same space monopolised by *Sedum pilosum*, new, rare and lovely though it be." This pursuit of unusual forms has even led him to establish what he calls a lunatic asylum, to which he relegates the more eccentric. Here, for instance, we are introduced to a pigmy form of *Elder* which started life as a *Witch's Broom*, and to "the first crazy occupant," a *Hazel* so twisted that "it never produces a bit of straight wood."

Another instance of the results of the long-continued search for various forms is that, in spite of his complaint that his garden is not very well suited to *Snowdrops*, Mr. Bowles has got together so many different species and forms of this flower that the descriptions of them—with sundry excursions—occupy some twenty pages.

A whole chapter is devoted to a description of a separate garden of plants with silvery leaves or with the variegated foliage for which Mr. Bowles frankly confesses his admiration. A few purple-leaved trees and shrubs, such as the purple-leaved *Peach*, are introduced to heighten the effect of the pale foliage of the majority.

The chapter on spring-flowering *Crocuses* occupies some thirty pages, but the impression left by a recent visit to the frames and seedling beds makes it seem probable that several chapters of this length could easily have been written if all the beautiful seedlings that have

appeared there had been described. There is certainly a rich reward in store in the shape of a harvest of bloom when flowers are scarcer for those who follow in Mr. Bowles' footsteps and start a cold frame or two for the early-flowering *Crocuses*.

Early *Irises*, *Daffodils*, *Primulas*, *Anemones* and *Tulips* have each a chapter to themselves, but the subject is so broadly handled that frequent digressions occur. These deal with other flowers in bloom at the same time, with the structure of moraines, with collecting in the Alps, and even with the pigments that the artist must choose and combine if he is to depict the true colours of the flowers that are described.

The style in which the book is written is decidedly conversational; but if this occasionally has its drawbacks, it allows of a free introduction of amusing incidents and horticultural anecdotes. The tale of the wiles of the old man who for years provided a firm of druggists with an abnormally cheap supply of *Hemlock* is certainly worth recording, and it is interesting to find that there is no truth in the story of the theft of *Caltha polypetala* from the Vatican Gardens. It was always alleged that one member of a party engaged the attention of the gardener by inquiring as to the whereabouts of the stables in which the famous Papal bulls were kept, while another hooked fragments of the giant *Kingcup* out of the pond with the handle of an umbrella and secreted them in its folds.

Of misprints there appear to be very few, but the difficulty of the last sentence on page 119 is increased by the fact that "derivatives" occurs instead of "derivations."

The illustrations are numerous and of two kinds. There is a set of twenty-four excellent reproductions of photographs of views in Mr. Bowles' garden, and in addition there are sixteen coloured plates of various flowers, mostly reproduced from the volumes of the "Present Day Gardening Series." The latter seem to vary greatly in faithfulness to the originals. Some are successful, but *Iris susiana* has become

quite red, and *Iris longipetala* has taken on a shade of pink which it does not wear in nature. The plates of *Tulips* seem to show that it is still difficult by this mechanical photographic process to get both the reds and pinks of the flowers and the varying shades of green in the stems and leaves. It is a pity that the plates seem to have been scattered at random throughout the book instead of being inserted, as far as possible, where they would face the text that they illustrate.

In this description of his garden in spring Mr. Bowles has given us a book which is at once entertaining and instructive; and, if only our gardens contained half the treasures to which we are here introduced, they would gain greatly in interest and beauty. *W. R. D.*

ORCHID NOTES AND CLEANINGS.

DISA SAGITTALIS.

A SMALL batch of this pretty little *Disa* is flowering with Messrs. Flory and Black, Orchid Nursery, Slough, where it proves to be very free-growing and produces its flowers in profusion, although the other small-flowered *Disas* have a reputation for being difficult to cultivate. It is hoped to obtain a new race by crossing it with some of the showier hybrids, which are also about to flower. The stems rise from a tuft of leaves, are clad with close-fitting whitish bracts, and bear on the upper part six or eight white flowers slightly marked with rose-purple, and of very singular structure. The plants, which bear five to eight spikes each, are grown in the *Odontoglossum* house with the other *Disas*, which seem to like the position, home-raised seedling *Disa grandiflora* having flowered there in fair quantity.

HYBRID ORCHIDS.

(Continued from page 87.)

The names and parentage are those given by the owners of the plants.

Hybrid.	Parentage.	Exhibitor.
Brasso-Cattleya Sylvia	B.-C. Digbyano-Trianae x C. Trianae	Sander and Sons.
Cattleya Cappel	Trianae x Schröderae	Armstrong and Brown.
Cattleya Domitian	Harrisoniana x Schröderae	Armstrong and Brown.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

SUMMER-FLOWERING ONCIDIUMS.—The warm-growing *Oncidium*s are producing their flower spikes, and need a liberal treatment to assist them to develop their flowers. One of the most serviceable species both for exhibition and decorative purposes is *O. Marshallianum*. This plant often produces several dozen large flowers which are coloured yellow and brown, and this free-flowering characteristic is probably the cause of the plants deteriorating early. After two or three years in cultivation the plants become weaker, and the pseudo-bulbs smaller year by year. I draw attention to this fact so that everything may be done that will contribute to the plants' well-being, such as removing the flower spikes within a reasonable time after the flowers have expanded. The production of these huge spikes of bloom entails a great drain on the plants' energies, and if they remain for long after the flowers are open the pseudo-bulbs will shrivel, and plants affected in this way rarely regain their former vigour. Large specimens of the tufted-growing species such as *O. obryzatum*, *O. haematochilum*, and *O. flexuosum*, are all useful when well flowered. The best time to undertake re-potting is immediately after the plants have finished flowering, for then the roots are in an active condition. I find that the plants derive considerable advantage from leaves mixed with the potting compost. Many *Oncidium*s that I found were difficult to cultivate grew satisfactorily when the compost contained at least one-third its bulk of broken Oak and Beech leaves. The other materials should be peat and moss, with plenty of sand and broken crocks added to render the compost porous. The greatest care is necessary at this season of the year to keep the growths and flower-scapes free from thrips, green fly, and other insect pests. It is a good plan to spray the plants in the different houses with an insecticide on frequent occasions, whether insects are observed or not, for then there will be little danger from this trouble during the spring, summer and autumn months. Vapourisings are best in winter, for if spraying was resorted to then the foliage would remain wet for too long. Even at other times spray only when the weather is fine and dry. Where yellow thrips have infested such close-growing plants as *Miltonias* and *Cypripediums*, it is a difficult matter to eradicate the pests. A red, rusty appearance of the leaves and on the inside at the base of a new growth is a sure indication of the presence of thrips. In cases of very bad infestations the plants should be dipped into the insecticide, but do not wet the potting compost. Let the plants afterwards be placed on their sides to drain. This treatment should be practised weekly for a time, and, when satisfied that the pests are destroyed, spray with the insecticide as recommended above. It is much better to use any specific at a slightly weaker strength than advised by the manufacturer, for an overdose may prove very harmful to the plants.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Maddesfield Court, Worcestershire.

PREPARATIONS FOR PLANTING ANNUALS.—All borders of beds which were manured and dug roughly in the autumn should be well dressed with soot in fine, dry weather, and the soil broken with a fork to prepare a fine tilth in readiness for planting. This early preparation of the soil will allow for the ground to become settled again before planting time arrives, and no amount of trouble taken in this matter can be considered too much. The soot will make the soil untenable by slugs and other insect pests: no small boon when the young, tender plants are put out. Meanwhile push

forward with the work of pricking out into boxes or cold frames a suitable number of each kind of plant for furnishing the beds. Use good friable soil and transplant the seedlings before they become crowded in the seed-bed. The importance of thin sowing, transplanting early and growing the plants stocky cannot be too strongly emphasised, as once seedling annuals become crowded and drawn they are practically useless, for they can never be restored to a good condition. It is far better to sow one variety thinly in two boxes than to crowd the same number of seeds in one box. Moreover, the young plants when well apart in the seed-bed do not require such early transplanting. A select list of the best half-hardy annuals was given in the issue for January 24, p. 54.

DAHLIAS.—Continue to insert strong, healthy cuttings, taking them, whenever possible, with a portion of the old tuber at the base, or strong roots may be cut into portions with one or more eyes like Potatoes. For the first time we intend to include some of the Paeony-flowered varieties, and they will be planted in bold groups in the show garden. A few plants with their bright, shy flowers on long stalks, should, if the colours are well-chosen, make a fine effect in autumn amidst the greenery of grass and trees. In such parts of the pleasure-grounds with such surroundings there cannot be too many gay colours.

BORDER CARNATIONS.—Where wild rabbits can gain access to these plants in the beds, it is necessary to take up the rooted layers in the late autumn and winter them in pots in cold frames. In view of re-planting them the ground should be prepared in a similar manner as recommended for annuals. If planted out as soon as the ground is ready the plants will grow away at once and bloom satisfactorily.

TREE CARNATIONS.—Cuttings that were rooted last autumn, if treated in the same manner as the border varieties, may be relied upon to bloom freely all through the summer, and to continue in flower until frosts occur. Old plants left out all the winter have furnished a few good flowers as late as the time of writing, but this is unusual.

PINKS AND PICOTEES.—These flowers require much the same treatment as the Carnations. Pink Mrs. Sinkins makes a pretty edging to paths other than with grass verges, and the blooms are sweetly perfumed. Mule and other Pinks, such as Napoleon III., *Dianthus neglectus*, and many of the single varieties, should be planted amongst the stones in the paved garden, between stepping-stones, etc.

CALCEOLARIA AND MARGUERITE.—These plants should be removed from the frames in which they were rooted, and planted out in cold frames in friable soil, thence direct to their permanent quarters. It is a mistake to pot bedding *Calceolarias*.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOLE,
Eastwell Park, Kent.

THE LOGANBERRY.—This bramble is of very vigorous habit. Therefore, when planting allow plenty of room for the canes to develop without overcrowding. The plant is not very particular as to the kind of soil or the position in which it is planted, for it will succeed almost anywhere, but it thrives best in a good, strong loam that has been well enriched with manure. If only a few plants are grown the shoots may be trained on a fence or a wire-trellis in the kitchen-garden, where the plants will occupy but little room, succeed well, and be easy to get at. If trained on poles the canes should be retained their full lengths, for the Loganberry is a prolific cropper and well-ripened shoots fruit to their ends. The berries are a little later in ripening than the main crop of Raspberries, and provide a welcome addition to culinary fruits. They are also excellent for bottling if gathered before they are over-ripe. The plants should be afforded similar treatment to the Raspberry, that is, the old fruiting canes should be cut to the ground as soon as the crop is picked. Thin the young canes early, loop those

that are left out of harm's way in the early part of the season, and after the old wood is cut out train them in their permanent places. If this work has been overlooked it should be done now, and weak or immature shoots cut back to ripe wood. Established plantations should be afforded a heavy dressing of manure annually. Young canes may be planted now with every prospect of success, but a light mulch should be spread over the roots to protect them from drying winds.

BLACKBERRIES.—The common Blackberry, when well cultivated, has the best flavoured berries of these fruits, which are exceedingly prolific, and the berries are valuable for cooking and preserves. They succeed well when trained on a fence or trellis as a screen, for which purpose they are well adapted. A few bushes may be allowed to grow almost wild on the outskirts of orchards or in corners of the outside garden, and they will fruit freely if there is an old tree stump or heap of stones over which they can ramble. The Parsley-leaved variety, *laciniatus*, is a very ornamental plant as well as valuable for its fruit, and is suitable for planting in the wild or woodland garden.

THE LOWBERRY.—The Lowberry, raised from the Loganberry and Blackberry, succeeds under the same treatment as the common Blackberry. The fruits are long, jet black, and of Blackberry flavour.

FILBERTS AND COBNUITS.—The pruning of Nuts is usually left until fairly late in the season, but the work should be finished now. In market plantations the bushes are trained in the form of a cup or basin, the centre being entirely open. Grown in this manner the bush is restricted to a small size, making it an easy matter to prune the shoots and pick the crop. There is still time to plant young trees, but on no account select rich or recently-manured ground, or growth will be gross and unfruitful. All nuts grow well in poor, stony soils, and may be planted on sloping banks or boundaries which are not always suitable for other fruits. Being accommodating in the matter of soil Filberts and Cobnuts are often planted in out-of-the-way corners and allowed to suffer from neglect, but, like most crops, they repay for a reasonable amount of attention. After the work of pruning is completed fork the ground over, burying all annual weeds and leaves. Choose plants with clean stems, and rigorously keep down suckers. Good varieties to plant are Kentish Cob, Early Prolific Filbert, and Merveille de Bollwyller. The purple-leaved variety, apart from the value of its nuts, is well worth planting in the shrubbery or wild garden for its ornamental foliage.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

FIGS.—A temperature of 60° to 65° at night, and 75° to 80° in the daytime, will not be too high for the early house, with a rise of a few degrees by sun heat. The Fig delights in an abundance of heat and moisture, but plenty of light and fresh air are also essential, therefore admit air early in the day during warm, sunny weather. Continue to give the necessary attention to the work of thinning, pinching and tying the young growths where the trees are trained on wires or trellis-work, also thin the young fruits where they are growing too thickly. Follow the instructions already given on the management of pot-trees, by feeding and syringing the plants daily, or as required. The swelling of the young fruits may be hastened by affording top-dressings of rich soil and artificial manures, a little at one time, just sufficient to keep the trees in a healthy condition. Applying a little and often is far preferable to affording heavy dressings at long intervals.

VINES.—When the berries have passed the stoning stage the temperature may be 5° higher at night, always admitting a little air through the top ventilators. Close the house early in the afternoon when the atmospheric temperature is 85°. Whenever this temperature is maintained promote plenty of atmospheric moisture in the

vinery. The temperature for Muscats in bloom should be 5° higher than that recommended for Black Hamburg. If the temperature is 75° at night and 10° higher during the day, this will be suitable. To prevent sudden changes in the temperature admit air by degrees, as nothing is more liable to cause rust on the berries than draughts of cold air between the flowering and the stoning periods. Disbud, stop and tie the growths in later houses as required. If the shoots are stopped at three joints beyond the bunch it will be close enough to the main rod. Syringe successional vines several times daily, and start the other vineries to follow these. If the work has not been done already, top-dress borders showing signs of exhaustion with fresh fibry turf, mixed with a sprinkling of quarter-inch bones, or bone-meal. Prepare a similar compost for pot vines needing larger receptacles.

EARLY CHERRIES.—After the fruits have set they will grow rapidly, and syringing should be practised twice daily during bright weather, and but once only—early in the afternoon—on dull days. This will not only keep the foliage in a healthy condition, but assist in checking insect pests. Fire heat should be used only when there is a danger of the temperature falling below 45° at night. Admit air early in the morning, and thus prevent a stagnant atmosphere. Unless by sun heat, the day temperature should not exceed 65°. As the trees develop, the spur growths should be stopped when they are four or five inches long, but do not pinch growths required for extension. Remove entirely all growths that would cause overcrowding. Fumigate the house promptly for the destruction of green or black fly directly these pests are detected. It is better not to syringe the trees with insecticides after the fruit has formed—quassia would probably cause the fruit to have a bitter taste when ripe.

MELONS.—Fertilise the strongest flowers only, as the finest blossoms invariably produce the most perfect fruits. Superfluous male flowers should be removed, and laterals pinched at one joint beyond the fruit. When a sufficient number of blossoms is set, water the roots with weak liquid-manure, and use more moisture in damping the house. Syringe the trees freely on sunny days at the time of closing the house, as this will in large measure prevent attacks of red spider and thrip. Should green-fly appear on the terminal growths, dust with tobacco powder when the foliage is damp; do not fumigate if it can be avoided. Make another sowing to furnish successional plants.

CUCUMBERS.—If the plants are to be grown in a frame, prepare the materials for the hot-bed. Make the bed, say, about 3 feet 6 inches deep in front, and 4 feet 6 inches at the back, and place the frame and lights in position as soon as it is made up. Allow a few days for the bed to settle, then arrange the soil in ridges, or as mounds in the centre of each light. The compost should consist of loam, leaf-mould, and well-decayed manure, with the addition of a little charcoal or lime rubble. When the materials are warmed thoroughly set the plants in position. Take care that the heat of the bed is not sufficient to burn the roots—75° to 80° will be safe.

PLANTS UNDER GLASS

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

RICHARDIA ELLIOTTIANA.—The strongest of these plants are ready for transference to their flowering pots, and the more robust specimens may be grown in pots 8 inches in diameter. The compost should consist of two-thirds loam, one-third leaf-mould and manure from a spent Mushroom-bed, adding a good dash of coarse sand. Make the soil moderately firm, and afterwards grow the plants in a moist house where the temperature is 60° to 65°. Syringe the foliage daily and fumigate the house directly aphid is detected. When the pots become filled with roots, feed the latter with weak liquid manure and soot-water. Flower the plants in a greenhouse temperature; pot on successional batches as required.

ROSES IN POTS.—Plants that are coming into flower should be removed to a greenhouse or the cooler end of the conservatory. Take care to prevent cold draughts from reaching the plants and shade them from bright sunshine. Blooms intended for room decoration should be cut in the bud stage and placed in water in a cool place, where the wood and foliage will harden and the flowers last fresh much longer than otherwise. It is also advisable to cut Roses in the bud twelve hours before packing them in boxes for transit, treating them in the meantime as just advised. Climbing Roses, both pot plants and those in the borders, are on the point of blooming in the earliest house, and they also should be shaded during the warmest part of the day. Train in straggling shoots, and remove fading flowers. Feed the roots at this stage with liquid manure and soot-water diluted with clear water. If artificial manures are employed select one that does not give off an offensive odour. Keep the atmosphere fairly moist, and maintain a night temperature of 55°, the day temperature to be in accordance with the weather.

ANTHURIUM.—Turn the plants out of their pots and carefully remove as much as possible of the old compost. A suitable potting compost consists of two parts broken peat from which the dust has been removed by shaking, Spbagnum-moss, charcoal and fibrous loam one part each. Fill the receptacles half-full of crocks. Next lay on some of the coarse material and then work the compost carefully about the roots, keeping the stems of the plant well above the rim of the pot. Leggy specimens should have moss tied around the stem. Roots will develop in the moss, when the plants may be re-potted. Anthuriums should be grown in a brisk heat and moist atmosphere; the roots need copious supplies of water throughout the growing season.

THE KITCHEN GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

CELERY TRENCHES.—It is a great relief to get a big task like the making of Celery trenches out of hand and in readiness for the reception of the crop at the proper moment. I take every opportunity when other work is not very pressing to get it done—usually at this time. The large number of heads we require makes it imperative to have large trenches in which 200 to 250 plants may be set. These hold four rows at 1 foot apart, the outer rows 6 inches from either side of the trench, or a trench of 4 feet wide may be made with interspaces for the ridges of 4 feet 6 inches. The excavation need not be more than 6 inches in depth, for by going below the rooting level of the plants plenty of soil for earthing-up is secured, and at the same time a simple way provided for keeping the trenches drained during the winter months. Manure is incorporated with the soil, although I am aware that it is the usual practice to place it in a thick layer at the bottom with a covering of soil. The value of my practice is seen in dry seasons; during the drought last summer once the manure became dry it was a difficult task to moisten it again by watering. I could only partially water the crop twice, and though the plants drooped they grew splendidly on the break-up of the drought and less than a dozen bolted. I have only once grown another crop in the Celery trenches before the plants were ready for planting, but the result was so unsatisfactory I have never practised it again. But the ridges between the trenches may be cropped immediately with a variety of suitable vegetables, which will do splendidly in the great depth of rich soil.

THE IMPORTANCE OF THIN SEEDING.—I do not recommend thin seeding so much from a pecuniary standpoint, because in garden management this is scarcely worth considering; but it effects a great saving in labour, and, most important of all, a plant with plenty of space underneath and above ground makes more progress than one that is crowded and thus more or less starved from the beginning. As a rule all seeds are sown too thickly, one of the never-ending instructions one has to give being

to sow the seeds well apart and then to thin the seedlings so that each has plenty of room to develop. The evil of using too much seed is evidenced most clearly in leguminous crops, and in Peas especially. In Mr. Darbishire's book on plant breeding, he remarks that Pea "plants grown 9 inches apart set a vastly greater quantity of seed than plants grown 3 inches apart," which is incontrovertible. The largest and longest-bearing crop of Peas I have grown was from seeds set at 3 feet apart, and if the manager of a small garden could bring himself to grow Peas thus it would enable him to let loose for other crops a portion of ground less usefully occupied by Peas struggling for existence. And so with French Beans. I never sow these closer than 6 to 9 inches, and the seedlings are afterwards thinned. Scarlet Runners are treated in a like manner.

THE APIARY.

By CHLORIS.

PURCHASING REQUISITES.—Too often the purchasing of bee material is put off until it is actually needed; in some cases it is done because the beginner does not know how to anticipate his wants. Some appliance makers give special terms to those who order early, because, when the honey flow has begun, the work is so heavy that they cannot despatch the orders to time. The following hints may be helpful:—Each year a fair proportion of the combs should be removed in the brood chambers, because the cells gradually decrease in diameter, consequently a smaller race of bees is raised. This is caused by each bee raised in the cell leaving behind the cocoon in which it was reared. Buy brood foundation eight sheets to the pound. To purchase thinner foundation is false economy, because it may break down from the top bar during hot weather. The price is generally about 2s. 3d. per lb. Those who are working for extracted or run honey, as it is often termed, should fit up the shallow frame with full sheets of thin foundation with a drone base, not forgetting to wire it in, because the force with which its honey is removed in the extractor will be almost certain to break the comb from the frame. This is usually 2s. 4d. per lb. For comb honey purchase two bee-way sections, with a split top, which are generally 1s. 6d. for 50, and 2s. 9d. per 100, and larger quantities correspondingly cheaper. The foundation for these should be the extra thin; costing about 3s. per lb., remembering to use full sheets that are the full width, and falling short of the length by $\frac{1}{4}$ to $\frac{1}{2}$ inch to allow for stretching and to prevent buckling. To separate the sections use dividers made of metal. Those of the wooden type are useless. For hiving swarms and driving bees it is an advantage to have a good straw skep of ample size costing about 2s.

OVERHAULING THE HIVES.—The impatient bee-keeper must restrain himself for a little longer, for, beside losing valuable heat by opening the hives so early during inclement weather, he will lose brood, and incur the danger of the bees balling the queens and killing them. If there is doubt about the larder, lift a corner of the quilt for a moment, and supply the deficiency by placing a cake of soft candy, and let it be a large one, so as to cause no more anxiety for at least a month. Should the district be lacking in pollen-bearing flowers, then supply pea flour among shavings in a sheltered, sunny nook. I fear clean water will not be lacking in most districts, but should this be so, then supply it, for the bees will go to a contaminated source to get the large amount necessary to rear brood. Until the weather be more favourable be content to rake out through the entrance all dead bees. If Isle of Wight disease has carried off any colony do not omit to use a copious quantity of quicklime over the ground where the hive stood, and burn the frames, quilts, etc., used in the interior, then thoroughly cleanse the interior by using a blow lamp, such as painters and plumbers use, and follow this up by washing the whole hive thoroughly with a solution of Calvert's carbolic, and afterward leave open in the sunshine for the disinfection to be completed before using the hive again.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our Correspondents would oblige by delaying in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MARCH 23—
Birmingham and Midland Union of Horticultural Societies' Annual Meet and Concert, White Horse Hotel.

TUESDAY, MARCH 24—
Royal Hort. Soc. Coms. meet. (Lecture at 3 p.m. on "Pruning Shrubs.")

THURSDAY, MARCH 26—
Manchester and N. of Eng. Orchid Soc. meet. Roy. Botanic Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 42.7°.

ACTUAL TEMPERATURES:—
LONDON, *Wednesday, March 18* (6 p.m.); Max. 47°; Min. 40°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, March 19 (10 a.m.); Bar, 29.3°. Temp. 42°. *Weather*—Dull.

PROVINCES.—*Wednesday, March 18.* Max. 44°, *Yarmouth*; Min. 38°, *Spalding*.

SALES FOR THE ENSUING WEEK.

MONDAY—
Hardy Bulbs and Perennials, Roses and Fruit Trees. At 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.

MONDAY AND WEDNESDAY—
Roses, Shrubs, Hardy Perennials and Lilies. At Stevens's Rooms, King Street, Covent Garden.

TUESDAY—
Sale of The Wray Park Nurseries, 60, Holmesdale Road, Reigate, by Messrs. Peat and Holdsworth, at the White Hart Hotel, Reigate, at 7 p.m.

WEDNESDAY—
Perennials and Herbaceous Plants, Hardy Bulbs and Lilies, at 12; Paines and Plants, at 5. At Protheroe and Morris's rooms.

THURSDAY—
Roses. At Protheroe and Morris's rooms, at 1.

FRIDAY—
400 Unflowered Seedling Orchids. At Protheroe and Morris's rooms, at 12.45.
Hardy Bulbs and Herbaceous Plants. At Protheroe and Morris's rooms, at 12.

The Properties of Bacterised Peat.

Recent investigations have shown that peat when subjected to the action of bacteria becomes transformed into a manure of considerable value. The treatment required to bring about this result was devised by Prof. Bottomley, and consists in three stages. In the first stage the crude peat is acted on by certain bacteria, and as a result of that action large quantities of "humates" are liberated. In the second stage the humated peat is sterilised by heat, and in the third stage it is treated with a mixed culture of nitrogen-fixing bacteria (*Azotobacter chroococcum* and *Bacillus radicicola*). It is claimed that the sterilised humated peat encourages in a marked manner the activities of the nitrogen-fixing organisms, and that as a result the amount of soluble nitrogen-compounds is increased during the third stage of the process.

The foregoing facts are recorded with some detail in the *Gardeners' Chronicle* (October 25, 1913, pp. 290 and 295); the new observations made more recently and described by Prof. Bottomley in a lecture before the Royal Society of Arts on Wed-

nesday, March 11, are destined, if they are established, to prove of considerable importance both to science and practice.

Briefly, these new facts are that extremely small quantities of a watery extract of bacterised peat are potent stimulators of plant-growth. For example, it is stated, on the authority of Dr. Rosenheim, who carried out the experiments, that plants treated twice with the water extract of 0.18 gram (= $\frac{1}{550}$ oz.) respond very readily to the treatment and grow away from untreated "control" plants.

If the result of other more extended and similar experiments is to confirm the correctness of this observation we shall be face to face with a discovery of prime importance: for it is well nigh certain that this growth-accelerating effect of the extract cannot be brought about by the nitrogenous or other ordinary substances contained in that extract. The actual amounts of nitrogen—and of phosphorus—contained in $\frac{1}{550}$ oz. of the bacterised peat must be extremely small; far too small, as it would seem, to produce a marked increase in the rate of growth of plants potted in ordinary garden soil. To account for the phenomenon Dr. Rosenheim has suggested—albeit but tentatively—that bacterised peat contains substances similar to those discovered by animal physiologists in various foodstuffs. These substances—known as vitamins or accessory food substances—are held by physiologists to play a fundamental part in animal nutrition. Without their presence foodstuffs, no matter how rich they may be in the ordinary food materials—proteins, fats and the like—fail to nourish, and the animal, deprived of accessory food substances, languishes and dies.

These accessory food substances are derived by animals directly or indirectly from plants, and the well-known incidence of scurvy among sailors and others deprived for a long time of fresh vegetable food may be attributed, in the light of recent research, to the absence from the diet of accessory food substances. A further illustration of the vital importance of these substances is supplied in the disease known as beri-beri. It has been shown that this disease, which is widespread and increasing among Eastern peoples who live on rice, is due to the fact that as the result of the introduction of the modern steel roller the husk is removed during the preparation of the rice grain. It is in the husk that the vitamins are contained, and it is the lack of these accessory food substances that accounts for the disease of beri-beri. By adding the husk to the polished rice or by the addition of vitamins from other sources, e.g., from *Phaseolus mungo* L., the disease is prevented. Rickets, another malady which has long been ascribed to a disordered and poor nutrition, is now attributed more precisely to the deficiency of vitamins in the restricted and monotonous diet of the poor.

The observation that a watery extract of bacterised peat containing so little solid matter as 30 milligrams acts as a stimulator of plant growth has led Dr. Rosenheim to make the suggestion that no less

than in animal nutrition, so in plant nutrition, obscure accessory substances may play a part. The suggestion is one of great interest, but it must be received as it is given, with proper caution.

Coloured Supplement.—The subject of the Coloured Plate to be published with the issue for next week is a view in the Royal International Horticultural Exhibition of 1912, and it will be accompanied with a review of the *Horticultural Record*, the volume prepared by Mr. REGINALD CORY to commemorate the Exhibition.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will take place in the Vincent Square Hall, Westminster, on Tuesday, the 24th inst. At the 3 o'clock meeting of the Fellows a lecture on "The Pruning of Shrubs" will be delivered by Mr. E. BECKETT.

NATIONAL SWEET PEA SOCIETY.—A special general meeting of the members of the National Sweet Pea Society will be held at the Hotel Windsor, Victoria Street, Westminster, on April 20, at 2.30 p.m., for consideration of proposed alteration of rules. Notice of amendments, alterations, or additions must be sent to the secretary, Mr. HENRY D. TIGWELL, as per Rule 26, on or before March 30.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting of the Surveyors' Institution will be held at 8 o'clock in the Lecture Hall of the Institution on the 30th inst., when a paper will be read by Mr. W. W. JENKINSON, entitled "London Before the Fire: as Referred to in 16th and 17th Century Literature."

PRIMULA HYBRIDA LA LORRAINE.—A note and illustration in *Revue de l'Horticulture Belge et Etrangère* (No. 4, February 28, 1914) are devoted to the new hybrid Primulas raised by M. LEMOINE by crossing *Primula Veitchii* and *P. cortusoides*, the latter being used as the male parent. One of the hybrid *La Lorraine* is a vigorous and floriferous plant, and bears large rose-carmine flowers with a yellow eye. Another plant from the same cross (*Primula Ville de Nancy*) is characterised by lacinate, bright purple-carmine flowers.

A NEW PEACH.—According to a brief statement in *American Fruits* (March, 1914), Mr. E. H. WILSON, collecting for the Arnold Arboretum, has brought from his last expedition a Peach the fruits of which are as good as those now in general cultivation; but which have the merit of possessing a stone no larger than and as smooth and as easily detached as a Cherry stone. Truly, Nature, in her capacious heart, has a warm corner for gourmets.

TREES ON FARMS.—The movement among some English farmers to get rid of hedges and trees on their farms has called forth a weighty warning from a correspondent in the *Times*. This correspondent points out that the present hedges serve to isolate and hence to check the spread of contagious diseases among live stock. He also observes that if ditches are to go as well as hedges the drainage of the fields will suffer. It is interesting to observe in this connection that American farmers are beginning to appreciate the uses of trees. Thus, thanks to the missionary enterprise of the Forestry Extension Service of the Michigan Agricultural College, about a million young trees are to be planted this year in Michigan, and on one farm alone some 10,000 are to be put in. At the same time, the question of hedges requires attention, and there can be no doubt but that some hedges of the impenetrable thicket type should be grubbed up and replaced by others less massive, dirty and greedy.

Photographs by H. V. King

BALLS PARK, HERTFORDSHIRE, THE RESIDENCE OF SIR G. FAULDE-PHILLIPS, BART.

AMALGAMATION OF TWO HORTICULTURAL SOCIETIES.—The Walton Rose Society and the Weybridge Horticultural Society have amalgamated under the title Weybridge, Walton-on-Thames and District Rose and Horticultural Society. The new society will hold an exhibition in the Old Palace Gardens, Weybridge, on Wednesday, July 8. The secretary is Mr. C. ROWLAND, Weybridge Park Gardens.

NEW FLAGSTAFF FOR KEW.—In place of the flagstaff at the Royal Botanic Gardens, Kew, which was lowered recently owing to the decay at its base, the Government of British Columbia has offered to present a new pole, which measures 225 feet and has grown on Vancouver Island. Like the old example, this is a spar of the Douglas Fir, and when erected will be the tallest flagstaff in one piece in the world. The original pole was presented to Kew by Mr. EDWARD STAMP, of the firm of Messrs. ANDERSON, ANDERSON AND CO., timber merchants, dealing with the produce of British Columbia. This spar came from Vancouver Island, was 159 feet high and 20 inches in diameter at the base. The total height of the tree was 180 feet, and its age was estimated at 250 years.

A PARK FOR HUCKNALL.—To commemorate the coming of age of his son, Lord TITCHFIELD, the Duke of PORTLAND has given three recreation grounds and a park to Hucknall, near Nottingham. The park, known as the Waddow Park, has an area of about eleven acres, and the gifts are valued at about £20,000.

EXPERIMENTAL SHIPMENT OF AVOCADO PEARS.—The Director of Agriculture took home on his visit to England in November two cases of Avocado Pears which were carefully packed by Mr. ARNEAUD DE BOISSIERE. Through the courtesy of Mr. SKINNER they were stored in the vegetable chamber (the temperature of which is kept at 45° F.) during the voyage and they arrived in perfect condition. On examination during the voyage it was found that one was bruised but not ripe; this was removed. They were exposed for sale in a London fruit shop, and the prices realised for the shipper were 12s. per dozen for three dozen and 10s. per dozen for two dozen. The fruits presented a most attractive appearance, contrasting strongly with another consignment from the Canary Islands. The following report was received from the manager of the fruit department:—"The Pears were very good, and I would assure you that future consignments will receive our best attention." This experiment shows that Avocado Pears can be successfully shipped and sold at remunerative prices if stored at a temperature of 45° F. *Trinidad and Tobago Bulletin.*

A CENSUS OF THE GENUS ACACIA IN AUSTRALIA.—Mr. E. E. PRESCOTT, Principal of the School of Horticulture, Burnley, Victoria, has issued in pamphlet form a useful census of the genus *Acacia* in Australia. In his introductory remarks the author protests rightly against the custom of confusing *Acacia* with *Mimosa*, pointing out that the South of France is responsible originally for this error. The two genera may be distinguished by the facts that *Mimosa* has eight stamens and *Acacia* from four to many, and that the seed pod of *Mimosa* separates into one-seeded joints, whereas in *Acacia* the pod is two valved. The census shows that over 500 different forms of *Acacia* are indigenous to Australia, and of these forms over 400 are distinct species; thus *Acacia* is the most numerously represented of all Australian plants. To the Australian horticulturist they are invaluable, though paradoxically enough the chief difficulty of their cultivation arises from their love of neglect. Occurring naturally in poor soil, and accustomed to hardship in respect to water supply, many *Acacias* fail to take kindly to the more generous conditions of the garden. This, as Mr. PRESCOTT points out, is specially the case with the beautiful Golden Wattle, *Acacia pycnantha*, the natural

habitat of which is on the thin soils of silurian hillsides. Another rebel against soft conditions is *Acacia myrtifolia*, a dwarf species with cream-coloured and wonderfully fragrant flowers. *A. Baileyana* is one of the most beautiful and hardiest of all *Acacias*. This species, the Cootamundra Wattle, grows 24 feet high, with a spread of branches 38 feet in diameter, and a trunk of 2 feet in diameter. It lends itself kindly to cultivation, and does not resent pruning provided that the operation be carried out at or immediately after the flowering period. Other interesting species are *A. elata*, one of the real trees of the genus and *A. Saligma*, the weeping Wattle of Western Australia, a rapid grower with rich golden racemes. *A. decurrens* var. *normalis*, known commonly as the King or Sydney Green Wattle, is one of the noblest forms, but does not thrive near towns nor in a smoky atmosphere. In concluding his introductory remarks Mr. PRESCOTT expresses the hope that they may stimulate the planting of these beautiful Australian shrubs and trees, and for our part we feel sure that the wish will be fulfilled, for we have rarely read an introduction so concise and so interesting as that written by Mr. PRESCOTT. His love for the Australian Wattle is contagious, and cannot fail to infect others among the plant-loving members of the Commonwealth.

HORTICULTURAL EXHIBITION AT VERNET-LES-BAINS.—The Pyrénées-Orientales Horticultural Society, in conjunction with the Horticultural Syndicate, is arranging for March 28 and 29 a horticultural exhibition, to take place at Vernet-les-Bains. It is well known that many English people are to be found at Vernet-les-Bains at this time of year; the place and the time are thus well chosen for showing to visitors the value of the horticultural produce of the district. A detailed programme of the exhibition will be sent on application to the Commissaire Général de l'Exposition d'Horticulture, Vernet-les-Bains, Pyr.-Or., France.

SILENE SWERTIAEFOLIA.—A note in *Die Gartenwelt* (March 7, 1914) draws attention to the merits of this species, which, like *S. chlorifolia*, is a native of Asia Minor. *S. swertiaefolia* grows to a height of about 1-1½ feet, and bears the largest flowers of the genus. It requires a sunny aspect, a well-drained soil, and likes lime. The flowers, borne on stout branches in groups of three, are pure white on the upper side, brownish on the under side and on the calyx. The flowers are long lasting, and close at night and in cloudy weather.

U.S.A. PROHIBITION OF PLANTS BY POST.—The Board of Agriculture and Fisheries desires to bring to the notice of nurserymen and exporters of plants and bulbs that the importation by parcel post into the United States of all growing or living plants, seeds, and other plant products for propagation (except field, vegetable, and flower seeds), except in the case of parcels addressed to the Department of Agriculture, Washington, is now prohibited.

THE FUTURE OF COVENT GARDEN.—Mr. MALLABY DEBLEY, M.P., who recently purchased the Covent Garden Estate, presided on Wednesday last at the Annual Dinner of the Wholesale Fruit and Potato Trades' Benevolent Society. Replying to the toast of his health, he expressed the opinion that the market would not be transferred to another site, but that it would be developed and improved. He promised the salesmen as much fixity of tenure as could be given under the Charter, and said that they would be able to pass the goodwill of their tenancies to their successors.

PUBLICATIONS RECEIVED.—*The Horticultural Record.* By Reginald Cory. (London: J. & A. Churchill.) Price, £2 2s. net. *Gardening for Amateurs.* Part I. Edited by H. H. Thomas. (London: Cassell and Co., Ltd.) Price 7d. net.

BALLS PARK: HERTFORDSHIRE, (See Fig. 93 and Supplementary Illustration.)

LIKE so many estates in the Home Counties, Balls Park has had its due share of changes in ownership. The square, red-brick house was built some time about 1640, when the estate was acquired, through marriage, by Sir William Lytton, of Knebworth. It owes its name to an earlier owner, Simon de Ball, a Member of Parliament in King Edward's reign. Channyc's *History of Hertfordshire* describes the house as "a fair, stately fabric of brick in the middle of a warren, consisting of a square pile with a court in the middle thereof, every side equally fronted and exactly uniform, the ceilings within the house wrought with several and distinct patterns of fretwork, the steps in the great staircase paved with black and white marble, the inward court with free stone." Judging from the delightfully weathered brick, the exterior has remained unchanged, and the ceilings are still famous. In the middle of the seventeenth century Sir Wm. Lytton was deprived of his estate, and it came into the possession of Sir John Harrison, whose dame lived at Balls Park until her death in 1705, when she was succeeded by her son Edward. Then his daughter, the famous Lady Townshend, who "lived to be eighty, and gave the world and Horace Walpole considerable entertainment," became the owner. Various members of the Townshend family held the estate until it was acquired by Sir George Faudel-Phillips, Bart., who has effected considerable improvements. Previously the gardens were unimportant, and during the past century had been neglected, but the present owner's, eldest son, Mr. B. S. Faudel-Phillips, has so improved them, with the assistance of the gardener, Mr. F. Fitch, that they now rank amongst the finest in the county. The earliest work of any note was the transforming of an uninteresting kitchen garden into a series of charming hardy flower borders of the style shown in the supplementary illustration. The principal borders are a pair, each more than 120 yards long and fully 20 feet wide. In these borders the colour schemes are the chief feature. Commencing with white and grey, pink merges into yellow and orange, and the full reds occupy the centre. Along the back vigorous Roses, on poles and chains, of similar shades to the border plants, form a charming framing. The herbaceous plants, which are disposed in bold masses, are principally Delphiniums, Phloxes, Heucheras, Geums, Paeonies, Kniphofias, Eremurus, and Lilliums. There is no conventional rock garden, but several of the borders, edged with raised stone, provide admirable places for very many Alpines. Whilst Balls Park is primarily a summer and autumn garden—for at these seasons the magnificent borders are aglow with colour—it is also attractive in late spring, when Darwin Tulips, in 120 varieties, furnish a blaze of colour. As soon as the Tulips have finished flowering, their place is taken by annual Larkspurs, Heliotrope, and Ageratum. Throughout the summer and autumn all the borders are kept filled to their utmost capacity, and for this purpose Mr. Fitch grows large numbers of annuals for filling the blanks left by earlier-flowering perennials, whilst various Lilliums, planted amongst the border subjects, add further beauty. The original walled-in garden, which goes by the name of Nan's Garden, has been transformed into a delightful Rose garden, where large triangular beds, each filled with one variety of a pink or a red Rose and *Lilium candidum*, are edged with a broad band of *Saxifraga cordifolia*.

THE SUNKEN GARDEN.

Of Balls Park it may be said with truth that its gardens are in a wood. The flower garden,

part of which may be seen in Fig. 95, was made in a clearing of the tall, clean-boled Elms, Beeches, and Poplars, and on the other side of the lawn a dense Yew hedge forms a fitting boundary to the sunken garden shown in the lower half of the supplementary illustration, and which also possesses a rich, leafy framing. Such features of the garden are essentially for summer enjoyment, and during that season few more enticing places could be found. In the style and arrangement the influence of the Dutch Garden at Hampton Court can be plainly seen, but the pattern has been departed from sufficiently to stamp the Balls Park effort with an individuality of its own. It is deeper, more rectangular in shape, and in place of the moss-covered little central fountain is a leaden Cupid. Out from this delightful garden, where the surrounding trees cast patterned shades, and along a broad stretch of greensward, is the "Cottage Garden," with its terraces capped by Yew hedges and containing a formal Rose garden, where none but the yellow-flowered varieties are grown. From this point of vantage an easy and pleasant inspection of the long, broad shrub-

delightful sight; at the time of planting the large-flowered varieties were selected with a view to this spring effect. Carnations are grown in large numbers and with exceptional success, as witness the large, well-flowered "Malmaisons" exhibited at the R.H.S. spring shows by Mr. Fitch. More than 1,200 plants of *Souvenir de la Malmaison* varieties are grown, chiefly *Princess of Wales*, *Lady Coventry*, *King Oscar*, and *Blush Malmaison*. Several houses are devoted to *Perpetual Flowering Carnations*, which also evidence skilful culture, and of these the principal varieties are the *Enchantress* varieties, *R. F. Felton*, and *Beacon*. Other glasshouses contain a variety of such plants as *Poinsettias*, *Plumbago rosea*, and exceptionally large specimens of *Adiantum tenerum Farleyense*. A. C. B.

NOTES FROM WISLEY.

PLANTS IN BLOOM.

ON the rockery *Saxifraga apiculata*, *S. Boydii alba*, *S. Burseriana* and *S. Burseriana*

(Photograph by H. N. King.)

FIG. 93.—BALLS PARK : GARDEN FRONT, SHOWING PART OF ONE OF THE LARGE RAISED FLOWER BEDS.

bery border, which marks the boundary of the gardens, may be made.

The temptation to give this border a wavy outline has been resisted, and spacious dignity is derived from the straight boundary and ample greensward. Good taste and much skill are displayed in the arrangement of this noble border, which contains many uncommon shrubs. In addition to the splendid effect from the borders and flower-beds must be noted the large number of *Hydrangeas*, *Palms*, *Heliotropes*, *Plumbago capensis*, and kindred plants which are set out in tubs at points of vantage during the summer months.

THE GLASSHOUSES.

When the flower borders were formed on the site of the kitchen garden, eight acres of ground in another part of the estate were requisitioned for the growing of vegetables, and here the different crops all bear the stamp of good culture. The glasshouses were retained conveniently near to the house, and at the present season three Peach houses in full bloom are a

major are all flowering freely. A large patch of *Erica mediterranea hybrida* is in full beauty on the banks of the largest pool and the purplish colour makes a contrast with the greyish tint of *E. Veitchii*, which is flowering on the opposite bank. *Primula Winteri*, protected from excessive moisture by overhanging rocks, has been in bloom for several weeks. *Crocuses*, *Polyanthuses* and *Cyclamen coum* are flowering abundantly, while a fine colony of *Narcissus cyclamineus* is blooming in the wood adjacent to the rock garden. The Alpine house contains a good selection of plants in pots and pans, including *Primula megaseaefolia*, *P. Winteri*, *Anemone blanda*, *Saxifraga Burseriana* and its varieties *crenata* and *Gloria*; *S. oppositifolia*, *S. Boydii alba*, *Soldanella alpina*, *S. montana*, and *Saxifraga Grisebachii*. The last, although not yet in flower, is very beautiful with its numerous crimson-coloured bracts. A pan of the annual *Ionopsidium acule* makes a charming feature, while *Daphne Blagayana*, *Saxifraga apiculata* and *S. Faldonside* are all very attractive. Shrubs in flower include *Pieris japonica*,

which is laden with trusses of its white flowers, *Hamamelis arborea* (Witch Hazel) and *H. Zucariniana* are just past their best, but *Daphne Mezereum* and *Erica lusitanica* are both flowering profusely. The last-named is afforded some protection by neighbouring Bamboos and Conifers. The buds of *Pieris floribunda* are well advanced, and many of the flowers are already open. One of the most charming trees in flower is *Prunus Pissardii*. Plants in bloom on the moraine are *Saxifraga apiculata alba*, *S. Boydii alba*, *S. Burseriana Gloria*, and the small yellow *S. Paulinae*. C.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

HENRY J. CLAYTON MEMORIAL.—A wish has been expressed by some of the many friends and admirers of the late Mr. Clayton that a man so widely respected, and who was in every sense such a credit to our profession, should have his memory perpetuated by a "Memorial" in connection with the Royal Gardeners' Orphan Fund. It will be remembered by many that the suggestion for establishing this Fund by the Gardeners of Great Britain and Ireland, in commemoration of the Jubilee of Her Majesty Queen Victoria, originated in part with, and was most strenuously advocated by, Mr. Clayton, and it is generally felt that no other form of memorial would more greatly commend itself to the wishes of our late friend or to his family. From the establishment of the Fund in 1837 Mr. Clayton never ceased to advocate its claim to the support of the fraternity, as well as of the garden-loving public; and we know how keenly he rejoiced in its growth and prosperity, and to see the sum annually expended in relieving the necessities of destitute orphan children of his less fortunate brother gardeners grow steadily from £139 15s. in 1838 to £1,868 12s. 6d. in 1913. I hope that gardeners will support this movement with small contributions, which I will gladly acknowledge. *T. Turton, Hon. Sec. and Treasurer, The Castle Gardens, Sherborne, Dorset.*

APPLE W. CRUMP.—At last I have found an apple which for late keeping and really good flavour is worthy of extended growth. I allude to *W. Crump*, which was raised by its namesake at Madresfield Court. It is the result of a cross between *Cox's Orange Pippin* and *Worcester Pearmain*. In shape, size, and colour it is identical with *Worcester Pearmain*, but it has much more yellow colour in the skin, and the rich yellow flesh of *Cox's Orange Pippin*. On March 7 last I tasted a firm, solid fruit; the flavour was distinctly good, reminding me of *Cox's Orange Pippin*. E. M.

TRICUSPIDARIA LANCEOLATA SYN. CRINODENDRON HOOKERIANUM.—On p. 60 Mr. Jenkins writes of the difficulty in getting seeds of this plant to germinate. I may state that seeds have germinated readily this year, and around the parent plant in my garden hundreds of seedlings are springing up. *Frank R. Durham, Fairhaven, Salcombe, South Devon.*

HIPPEASTRUMS FROM SEED (see p. 158).—In Mr. Hart's note on the raising of seedling *Hippeastrums* he states that they take about three years to reach a flowering size, or at least only a few of the stronger ones flower when two years old. By growing them entirely in pots from the seedling stage we have no difficulty in flowering 90 per cent. of the bulbs in two years. The seeds are sown in boxes at 1 inch apart, and so soon as the seedlings have developed two leaves they are transferred into small sixty-sized pots, placed on shelves, and grown in a temperature of 65 to 70°. By the end of August the seedlings are ready for transplantation to 4½-inch pots, and are kept steadily growing all through the winter. At the end of the first year they are shifted into 6½-inch pots, and kept growing until the winter. They are then partially rested, but not kept dry enough to cause the foliage to drop. By the end of

February the majority of the bulbs are pushing up their flower spikes, and can then be brought into flower in a few weeks. This method of growing them certainly entails three times potting to Mr. Hart's one potting and one boxing, but one season's watering and attention is saved. Also, where large batches of seedlings are raised annually the sooner they are flowered and the poor ones weeded out the better. *C. Garratt, Highbury Gardens, Birmingham.*

FAILURE WITH FORCED BULBS (see p. 175).—We have experienced the same failure as Mr. Wilson with forced bulbs. Some varieties, such as Golden Spur and *Poeticus ornatus*, were a complete failure, but others, grown in the same conditions, were successful. Yellow and Red Duc Van Thol Tulips were also failures. Golden Spur Narcissus was rather strong in growth, but only 25 per cent. of the plants flowered. *Poeticus ornatus* started into growth and then stopped, but the bulbs rooted freely. The Tulips mentioned made weak growth and scarcely any roots. The bulbs were supposed to be of first quality, and were in a good condition when potted. *W. H., Cobham, Kent.*

AQUILEGIAS AND THEIR HYBRIDS.—One of the most beautiful and effective of all the Aquilegias is *A. coerulea hybrida*, most graceful in aspect. The original colours of this charming Columbine were blue and white; but, crossed with chrysantha, it has acquired distinctive, luminous yellow hues. *Aquilegia californica hybrida* shows an impressive blending of brightest orange and deep scarlet, though by reason of a somewhat pendulous tendency its lustrous beauty is much concealed. *A. canadensis*, the colours of which to some extent resemble those of *californica* (though yellow supervenes, as if for the sake of floral individuality), is also a very effective variety, which succeeds here admirably in garden loam. One of the finest members of this richly ornamental family is the Siberian *A. glandulosa*, which ever since its introduction into this country from the Alpine regions, has been a supreme favourite with all earnest cultivators of these fascinating flowers, so popular at present in Scottish gardens. *Aquilegia Skinneri*, which has yellow petals, with sepals of delicate green, is a native of Guatemala, in South America. It is not arduous of culture when grown in fibrous soil, but in my own garden, where nearly every variety of any consequence has been cultivated assiduously, I have found it short-lived. It is quite possible that it was assigned too shady a situation. *Aquilegia glandulosa*, to which I have already incidentally referred, is easily increased, like many other forms, by careful division at the roots as soon as it has developed its resources and attained its utmost strength. A derivative from this highly artistic inhabitant of the remote Altai Mountains—namely, *A. Wittmanniana*, though possessing very considerable attractiveness, is not equal in beauty, or even in facility of culture, to the peerless parent flower. The late Dr. Stuart, of Chirside, in Berwickshire, once said to me, with reference to his large and lustrous *Aquilegia* namesake (*A. Stuartii*), that it was somewhat difficult to grow adequately. "requiring very careful attention in its earlier stages, and a deep, fertile soil." I have been informed by its first introducers, the Messrs. Cocker, of Aberdeen, that it was the result of a cross between *A. coerulea* and *A. glandulosa*. One of the finest and least culturally exacting of all the Aquilegias is the "Golden Columbine," *A. chrysantha*. It should be found in every herbaceous garden where those glorious flowers are grown. *David R. Williamson.*

THE N.E.H.S.—The above society has held its third annual meeting and at last, more or less, equalised income and expenditure, there being a loss on the current year's working of only £22. This is excellent work, but the heavy initial expenses still remain as a drag on any forward movement, although some £105 was raised in 1913 towards reducing the expenses incurred in establishing the society. The subscription list shows a great increase, being £348 as against £277 in 1912, and £257 in 1911. But the problem that confronts all well-wishers of this northern society is this—will the Fellows and Members remain loyal, and will the increase continue now

that only an honorary and part-time secretary has taken the place of a paid and full-time secretary? Is the society this year holding out to Fellows distant from Leeds any benefits consistent with a guinea subscription? This remains to be seen. According to the belated list of arrangements there is little to offer to members distant from Leeds. Having watched the working of the society since its inception, I consider there have been three great hindrances to that progress, continuity and stability which is so necessary to a young organisation. First, the monthly shows were given up too soon. They were in 1911 the feature of the society, they kept the Fellows interested and the enthusiastic committee members busily occupied. Secondly, the society was badly financed at its start, for no guarantee fund was formed at the time when such might have been easily raised. And, thirdly, the N.E.H.S. has been under a great disadvantage in that it started on its career handicapped with rules and regulations copied wholesale from the R.H.S. Natural growth to a gardener should be of more importance than artificial imitation. These three great mistakes, lack of continuity, bad finance and ignorance of natural laws have been protested against without success. Another mistake is now being made—lack of tact and courtesy towards men who have borne the burden and heat of the initial fighting. A stupid policy of isolation is also being persisted in, which will make the society few friends and many enemies. In the North of England there are several old gardening societies whose goodwill might have been obtained and retained had a programme as broad and as long as the North of England been wholeheartedly outlined and adhered to. As it is, I prophesy that unless a change takes place we shall soon see the N.E.H.S. dead and buried, sharing the fate of other societies which have found the smoke and apathy of Leeds too much for them. It may survive for a few years, appealing to a few garden lovers in the Leeds district; but as for carrying out the work implied in its Articles, it is already lacking in loyalty to them, it is deficient in enterprise, and therefore cannot expect to win the horticulturists of the North of England over to its side, and lead them and guide them in their difficulties and aspirations. *J. Bernard Hall.*

MILDEW ON ROSES.—All lovers of Roses I think dread the attacks of this disease, to which some of our best Roses are subject. I was interested in last week's note by Mr. Beckett on the use of serum. The gardens here lie rather low, and I find it necessary to keep a sharp watch for any signs of mildew attacks, both inside and out. I have used grey flowers of sulphur with excellent results on vines and other plants indoors, but this is not so easily applied to Roses outside. Last year I used Gishurst Compound, an old remedy, which contains a large portion of sulphur, dissolving two ounces in a gallon of water by letting it stand four or five hours, adding two gallons of clear water and syringing once a week, starting early in the season, and not waiting until the plants were attacked. I was very pleased with the result, and I am using it every day this year on inside Roses, and so far with good effects. *A. J. H., Kent.*

ARBUTUS MENZIESII (see p. 182).—I was greatly interested in the description of the tree of *Arbutus Menziesii* at B yfordbury, especially to note that the tree fruits so freely. It would be very interesting to learn if the seeds are fertile. The tree here is still vigorous, and each year is covered with its beautiful white blossom, but it never fruits. The height of the tree is, as stated on p. 182, about 50 feet. The girth has increased since Mr. Elwes measured it in 1907, and is now 3 feet 10 inches at 3 feet from the ground. I believe the species is a rather difficult subject to increase. There are growing here several large specimens of *Arbutus Unedo*, the tallest specimen being about 30 feet high. The variety *canariense* is, to my mind, superior to the type. The blooms are tinted with rose, and the fruits are more abundant, but rather smaller. It is a great pity that birds are so fond of the berries, as a hush of *Arbutus Unedo*, or *canariense*, in full fruit is a beautiful object. *Herbert Silcock, Bassett Wood Gardens, Southampton.*

JOURNEYMAN! GARDENERS' WAGES.—Correspondence on this question seems to be wanting in definiteness, and in assumption is not always correct. How devoid of foundation is the taunt thrown at the head gardener that the interests of his subordinates are nothing to him! In the abstract it is self-evident that the younger men are indebted solely to the head gardener for training—unrequited on their part—and for advancement to the position of heads themselves. In the concrete, I may be allowed to state in a few words what I have been fortunate in getting done for them collectively in one place. The foreman's wage has been increased by 65 per cent., the others not so much, but at present I am in consultation about a further increase for them. The bothy—though it is now a better house than my own, and "bothy" is quite an inapplicable term—has been made to twice the dimensions and refurbished, and instead of the woman devoting only a small part of her time to the men's wants, she has for years been engaged exclusively attending to their comforts. The half-holiday every Saturday is now an old institution. Every garden in the locality has not seen an equal progress, but many gardens have, and the same conditions are evident elsewhere. On the other hand, in only a few cases have the head gardener's emoluments been increased, some remain stationary, and others have actually decreased. This no doubt is due to the applicant asking a small wage at time of engagement. Where, in addition to the wage, milk, vegetables, and light is given, the estimate of a correspondent that 8s. can be saved out of 18s. is well within the mark. Young men have told me that their monthly bill for food rarely exceeded 20s.; but that was some years ago, and no doubt a considerable addition must be made to meet not only the inflation of prices, but the more expensive habits of young men. If a comparison is made with the artisan who has a bare wage with deductions for lost time, I think the condition of the gardener will be seen to be not so unenviable as some make out. There are other points I would like to note. Premiums for one. Did it ever strike the present-day youngster that there was a reason for premiums? Consider for a moment. There are a number of institutions run for the instruction of women in gardening, the fees charged for which would open the eyes of young men, and they give their labour gratis. For French gardening I have known a premium of £100 to be asked and given with a student. It is the same in other callings. Many a gardener could tell of members of his family who have worked for nothing for years, or for a remuneration that scarcely kept them in clothes, with, in some cases, pretty stiff fees in addition. Why, therefore, should a head gardener who instructs his subordinates, either directly or indirectly, be blamed for asking an equivalent? I have never asked a premium myself, but am quite convinced that there is nothing wrong in the principle, else it is also wrong in other cases. I think it is clear from the tone of the correspondence that the further self-evident fact that the privilege of being employed in gardens is worth something has been overlooked. And not only employed, but having the means provided of gaining a thorough knowledge of all the practical parts of horticulture and an intimate acquaintance with the plants of the garden, their culture and uses, whether vegetables, fruits, or flowers. A young man may be so devoid of a desire to obtain knowledge that he merely picks up the scraps that come in his way; but surely it is patent that there is nothing connected with horticulture, practical and scientific, useful and ornamental, that he may not appropriate. If such be the case, and it is the case, then the young gardener obtains for nothing his training, others being obliged to pay for theirs—either by premium and their labour included, or by a remuneration so low that their guardians have to practically keep them till trained. It is, then, after having obtained his training, and he assumes the supervision of a garden with its numerous ramifying annexes, that the hardship of the gardener's vocation appears. There are employers who, without a doubt, cannot afford to give a high wage. But no one can truly conceive of this being a general condition of the employing classes, and the difference of a pound a week more or less to the gardener's wage would never

be felt by the great majority, and to him, and his wife, it would not only be wealth, but, far better, a translation from a life of worry to a life of comfort and peace. Clearly, the solution is in the hands of the young men themselves. I have been astonished over and over again when informed of the sum the applicant for a gardener's situation has asked, when I knew that he might have had more for the asking. It is true that the outlays of many gardeners are diminished by, in addition to a free house, coals, light, and vegetables, but the tendency for some years has been in the direction of reducing perquisites. A cow, or its equivalent in money, seems to be a thing of other days, and there are other little things which kept down expenses or added to the comfort of his family, e.g., medical advice and medicines, which have gone the way of the cow. The acknowledgment from the seedsman, which not all of us depended on, must have been keenly missed by many a gardener. *An Old Hand.*

—I quite agree with *Salisbury's* remarks as regards stopping wages for time off; but I do not think that in most cases the head gardener is to blame. For instance, I myself (as head) took

mained twenty-two years. This afforded me an opportunity of forming an opinion of many young men and boys. I am pleased to say several of them proved excellent men, and are now holding permanent positions. I am convinced that if the young men of the present day would take more interest in their work, instead of grumbling and watching the clock, it would prove to their credit and advantage. *T. Lockie, Diddington Hall Gardens, Huntingdon.*

ALPINE GARDEN.

EUPHORBIA BIGLANDULOSA.

FOR the past two years throughout the winter months this fine Spurge has been the brightest plant on the Glasnevin rockery. The telling colour is particularly welcome at this time of the year, the long shoots hanging over a large rock giving a fine effect. In strong specimens numerous sturdy shoots arise from the rootstock, some nearly half an inch in diameter. These shoots are densely clothed with glaucous

FIG. 94.—EUPHORBIA BIGLANDULOSA FLOWERING ON THE ROCKERY AT GLASNEVIN BOTANIC GARDEN.

a week-end off to go and see my friends, and the Saturday following a day's pay was deducted. I could not help thinking this very mean, especially considering the extra time one puts in during the year—often on Sundays—without extra remuneration. *J. G. S., Surrey.*

—Having been much interested in the letters of your correspondents on the above subject, I beg you will grant me space to report my experience of fifty years ago. At the age of 19 I was sent as journeyman to a noted garden near Ascot; wages, 12s. per week including bothy. This included Sunday duty and attending fires of an evening. The bothy was simply a back shed on the north side of a range of glasshouses, without ceiling or plaster of any kind, and during windy weather we had a great difficulty in keeping the tallow candle burning; but the climax was reached in the month of November, when, owing to shorter daylight, our wage was reduced to ten shillings per week. Being interested in my work, I soon found employment elsewhere, and was much better treated. This encouraged me to persevere and gradually improve my position, and at the age of thirty I was appointed as head, with a staff of fifteen men and boys under my charge. Here I re-

leaves, which have a very distinct spiral arrangement. The stems grow upright for 18 inches to 2 feet, and then bear the bright yellow heads of flowers. As in other Euphorbias, it is the bracts which are the attractive part of the inflorescence. The flowers are small, and appear later on between two curious yellow glands. Some of the stems lengthen to 2 or 3 feet, lose their erect position, and hang downwards. The plant may be increased by cuttings or raised from seeds.

Euphorbia biglandulosa (see fig. 94) is a native of Greece and Asia Minor, and will make a plant from 3 to 5 feet across, according to the richness and depth of soil. *C. F. Ball, Glasnevin, Dublin.*

ADVISER IN FORESTRY.—It is announced that Dr. D. B. OSMASTON, of the School of Forestry, Oxford, has been appointed adviser in forestry to a group of counties, of which Kent is one. Landowners or others who desire advice on the management of woodlands can avail themselves of his services free of charge, but they will be asked to contribute towards the forest officer's travelling expenses.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

MARCH 10.—*Present*: Mr. E. A. Bowles, M.A. (in the chair), Dr. A. B. Rendle, Sir J. T. D. Llewelyn, Canon Fowler, Messrs. Shea, Hales, Fraser, Gordon, Holmes, Worsdell, Worsley, and Chittenden (hon. sec.), with Mr. Goodwin, visitor.

Narcissus hybrids.—Mr. GOODWIN showed a hybrid between *Narcissus cyclamineus* and *N. Golden Spur* flowering now from seed sown four years ago. Like most of the cyclamineus hybrids it has poor weak foliage, but the con-coloured flowers had the broad perianth pieces reflexed and a long corona somewhat frilled and expanded at the mouth.

He also showed *N. Leedsii* Minnie Hume × *N. Jonquilla*. This had rush-like foliage as tall as that of *Minnie Hume*, and the yellowish flowers retained the *Jonquil* scent, though rather toned down. The hybrid is called *Fragrance*, and was raised by Mr. Copeland.

Mr. GOODWIN referred to the prevalence of the fungus *Fusarium bulbigenum* this year, and thought the only effective method of dealing with it was to lift all plants showing yellowing of foliage and to remove the remains of bulbs where blanks occurred.

Zizania sp.—Sir JOHN LLEWELYN referred to the species of *Zizania* cultivated in England, and said that *Zizania aquatica* always proved an annual, but the plant grown under the name *Z. latifolia* was a perennial. It did not flower, and there had therefore been no opportunity of verifying the name. A plant under that name was mentioned in Gray's *Flora of North America*, and was thought to be the same as *Z. miliacea*.

Pelargonium hybrids.—Mr. FRASER continued his remarks upon the scented *Pelargonium*, dealing with the forms belonging to *Pelargonium capitatum* and its hybrids.

Intermittent variegation.—Mr. HALES referred to the matter of intermittent variegation which had been brought to the attention of the Committee some time ago, and said that a plant of *Sedum Telephium*, at Chelsea, after showing no signs of variegation for three years, had this year become markedly variegated again.

Small narcissus fly.—Mr. SHEA showed numerous specimens of the larvae of the small *Narcissus fly* *Eumerus lunulatus* (*E. strigatus*). He said they were proving particularly troublesome in his garden, and that he was lifting all bulbs which failed or showed signs of weakness. A large number of the larvae was often found in one bulb, up to 80 in one case, and 32 in another. Plants growing in the sun appeared to be more liable to attack than those in shade, as is usually the case with bulbs attacked by the large *Narcissus fly*. He thought it probable that the larvae travelled from bulb to bulb in the soil.

[An illustration of the *Merodon narcissi*, a related syrphus fly, was published in *Gard. Chron.*, October 12, 1912, fig. 124.]

"Reversion" in *Odontioda*.—Mr. R. A. ROLFE showed a flower of the cross *Odontioda Bradshawiae* Cookson's var. × *Odontoglossum spectabile*, from the collection of Clive Cookson, Esq., Wylam-on-Tyne. The flower closely resembled the *Odontioda* in shape, but the scarlet colour was entirely suppressed. The flower was white with a few light brown spots round the yellow crest of the lip, and a little brown spotting at the base of the lateral sepals.

Fasciation in Robinia Pseudacacia.—Mr. BOWLES showed a branch of *Robinia* from a garden at Eufield Lock exhibiting this phenomenon.

Axile proliferation in Quince.—Mr. J. CHEAL sent a branch bearing a fruit-like swelling from the apex of which a strong, woody shoot had grown, bearing foliage and buds. The succulent flesh of the fruit had shrunk to small proportions by this date, but in October had been of the usual bright colour and consistence.

HORTICULTURAL CLUB.

THE SPRING BULB SHOW OF 1914.

MARCH 10.—The monthly dinner of the Horticultural Club was held at the Hotel Windsor, on the above date.

Sir Harry Veitch presided over a company of seventy, which included the following guests from Holland:—Mr. E. H. Krelage, President of the Dutch Bulb Growers' Association, Mr. Wentholt, secretary; and Messrs. John Hoog, Jan de Graaff, A. Byvoet, G. H. van Waveren, A. Guldemond, J. M. V. van Zanten, and others.

After dinner the Rev. J. Jacob urged the need for early bulb shows in London and in other large towns. His special hobby at the present was the miniature Hyacinth. There were few exhibited that day, and he could not help thinking that the miniature Hyacinths supplied by their Dutch friends were not very good for the purpose. The typical miniature Hyacinths with a spike like the Roman Hyacinth were Orange Boven, Fleur d'Or, Grand Maître, Gen. de Wet, William III. and Queen Wilhelmina. Three or four of these bulbs would make a nice little display, and if their Dutch friends feared their trade was leaving them, they had many varieties, and a little searching might bring to light just what was wanted. The William III. was a very dark blue and made a beautiful show. The same could be said of the Orange Boven. The Grand Maître had a middling shade of blue—a shade he was very fond of himself and one that had many admirers, although he was quite ready to admit that plenty of people preferred a paler form, while others would like a darker one, such as King of the Blues or King Alfred or Prince of Wales. Two varieties which rather pleased him were Koh-i-noor, a rich pink, and a white variety, which was extremely beautiful. He could not understand why the red Hyacinths were not so high in quality as the pinks and the blues. There was something washy about the red. It did not look quite happy and seemed to need a filip of some sort. King of the Scarlets was a pretty one. As to the Tulips, he could only touch on one or two points. He was very glad to see Mr. Dawkins' exhibit of Darwin Tulips, and to think that he would in the future be one of the supporters of the Spring Bulb Show. The sensation of the year, so far as it had gone, in the Tulip world, did not seem to have been present that day. He referred to Sweet Lavender, which was their old friend William Copeland. Other beautiful varieties were Prince of Austria, Cherry Ripe and Brunehilde. He could not help feeling that there were still a great many early varieties of Darwin Tulips to come from Holland. Some varieties when in Holland two or three years ago were of a miserably dingy colour, yet Messrs. Carter and Messrs. Barr had done much to show them in better colour, and there might be other varieties that would respond with equal readiness. A great deal was to be done by forcing—some considered there was loss of character—but he understood that Sweet Lavender responded to a fairly moderate heat—somewhere about 70°.

As to Daffodils, he was especially pleased to see the exhibit of Messrs. Carters. He did not think they wanted only cut flowers. They were very beautiful; but they wanted to see bulbs growing in the actual soil. Nothing could give so good an impression as the bulb itself growing before their eyes. Another type of Daffodil was what he had called the New Poetaz. The old Poetaz kinds were put into commerce a good many years ago by Messrs. Van der Schoot. They were told by the Narcissus Committee that morning that these Poetaz were raised by Messrs. Van der Schoot somewhere in France. ("No.") He did not believe that was true. The tale must have gained credence because undoubtedly in the early stages when Poetaz were put into commerce the English people did not take to them at all, and the French did. Long before he saw Poetaz in an English catalogue he was able to buy them from Messrs. Vilmorin, in Paris. That was perhaps how the myth had arisen. Now they had another series with rather thicker stems and broader leaves, and probably more flowers. He was glad to see on Messrs. Barr's stand some very nice specimens. One of these was called *Admiration*, a charming specimen, which he could strongly recommend.

He had grown a certain number of this type himself, and he believed that in one he had called Orange Blossom they had a most excellent variety. Here he would suggest that for pot plants there should be a price limit, as it was absurd to expect people to give 10s. a bulb or more to grow in pots. He thought 10s. a dozen would be nearer the mark, and there were not many people who would pay 10s. a dozen to grow Daffodils in pots. They should be grown under glass, and shown on the ground. If they had good prizes for such a class it would be very instructive, and give them many wrinkles. He next suggested some good Daffodils for pots. What was wanted was early Daffodils with red eyes. They already had some very beautiful yellows in Golden Spur, Henry Irving, and others. Then there were Firebrand, Blackwell (one of the very best, so excellently shown by Messrs. Barr), Lucifer, an extraordinary flower, which would stage well, Robert Browning, Fairy Queen, Torch, Beethoven, and Queen of Spain. Speaking of Freesias, he said that when they had another bulb show some of these beautiful flowers would be seen there. As to Lachenalias, there were several beautiful varieties, and grown in 3½ in. pots, three good fat bulbs in a pot, they made most excellent little plants for putting on a small table.

Coming to Hyacinths there were Dorothea, May, Charles Dickens (double blue centre), Prince Bismarck (Christmas flowering), La Victoire, Queen of the Pinks (sport from King of Blues), Ivanhoe (dark sport from King of the Blues), Lord Balfour (bright and clear, and early), Cardinal Manning (earlier than La Victoire), Louis Pasteur, Prince Henry, Princess Juliana, Queen of the Netherlands, Purity, Parsifal, and Count Zeppelin. He wished to congratulate Messrs. Dobbie on their display of Circuses.

THE DUTCH POINT OF VIEW.

Mr. E. H. Krelage (President of the Dutch Bulb Growers' Association) thanked the company for the reception accorded to himself and his colleagues. The Bulb Show was the reason for their presence that night. It was an outcome of co-operation, and another outcome of it would be the Tulip trials to be held at Wisley this spring. The R.H.S. and the Council of the Dutch Bulb Growers' Society were trying to give that co-operation a permanent character, and on the proposal of the Dutch Society the Council of the R.H.S. had decided to enlarge the existing Daffodil and Tulip Committee, thus leading to the possibility of the addition of a number of Dutch specialists to the Committee. This would be another example of international judging of new garden plants. It was not the first time that it had been done, for new Roses had been judged by an International Committee in Paris for several years. This would now be done in London in the case of Tulips; and it was a matter of the greatest importance that similar arrangements should be made for all garden flowers. A certificate or award given by an International Committee would be of far greater value than any certificate from a National or Royal Society. For eight years in succession the Dutch Bulb Growers' Society had been allowed by the R.H.S. to offer prizes for forced Hyacinths at one of the March meetings in the Horticultural Hall. This competition had resulted in the important two-days' R.H.S. Bulb Shows, which had become one of the features of the horticultural year. His Society was very grateful to the R.H.S. for the opportunity thus opened up to awaken the interest of the amateur and the professional gardener in the Hyacinth. It would perhaps never completely regain the immense popularity it enjoyed in the 'sixties and 'seventies of last century, but, nevertheless, the times when Hyacinths were never to be seen in the Horticultural Hall were past, and year by year new names were among the prize-winners in the competitions, while the exhibitors had attained a remarkable standard of efficiency. The flowers shown by the Duke of Portland and the Marquis of Salisbury were as perfect as they possibly could be, and this was the more remarkable because Hyacinths did not force well this season. He thought, however, that the method of showing Hyacinths could still be improved. Messrs. Cuthbert's exhibit was a decorative display of the best kind, but the Hyacinths as a whole did not make such a charming

picture as did the Daffodils. The Daffodil might be a more graceful flower than the Hyacinth, and this gave it a better chance of artistic arrangement; but the Hyacinths would make a better impression if the flowers could be shown in a more convenient way, such as grouping them together, and not mixing them up with other exhibits. The colours of the Hyacinth were so distinct from those of any other flower that a combination was always a great risk, and as a rule did not give satisfaction. Hyacinths should be shown on the ground in groups of one variety, just as they might be used in the garden. They then made a far better impression than on tables, or even against the wall or roof of a building.

RAISING NEW HYACINTHS.

Mr. Krelage next gave a review of such new Hyacinths as were likely to become leading trade sorts in the near future. New Hyacinths were the results either of crossing or of sporting. Sports in Hyacinths were numerous, and some varieties had a remarkable tendency that way. The well-known single blue Charles Dickens had sported to the double blue, and the single red, form of the same name; while the double blue had again produced a double rosy sport which was known under the name of Lohengrin. The single white La Grandesse had produced a sport with double flowers. From the double blue Van Speyk a double pink originated, which was named Leo XIII. Raising seedling Hyacinths took a man's lifetime. The results of what he sowed in his youth he could only appreciate when his hair had become grey, and if he started at a more mature age it was often doubtful whether he would personally gain any financial profit. The Hyacinths which were now making their first appearance on the market must have been raised many years ago, and that they were satisfying the demand of the present day was a proof of the growers' perspicacity. This did not mean that Hyacinths as a rule had been raised by crossing special varieties. This may have been done occasionally, but as a rule the new Hyacinths had originated from varieties selected for seed bearing, which were expected to be fertilised by the wind or by insects with pollen from other choice varieties growing close by. The qualities of the existing trade varieties of the Hyacinth were so excellent in many respects that it was not easy to beat the older sorts. From time to time the older sorts, however, were disappearing from the market, because of disease or degeneration, and they must be replaced by new forms which possessed full vitality and could stand the modern methods of rapid propagation. One of the chief points in judging the merits of the Hyacinth in our days was the spike. If it was so strong that it did not want any tying the flower would have a better sale than when the stalk was weak. This explained why Gertrude was preferred to Moreno. Early forcing quality was another desideratum, and if a Hyacinth proved to be an easy Christmas bloomer it would everywhere have a splendid sale. In this connection he mentioned the first novelty he wished to refer to. Prince Bismarck was doubtless the best blue Hyacinth for Christmas forcing. The name indicated that it was not absolutely new; indeed, it was known for many years, and it was generally considered a rather poor thing, only good enough for the mixture. Only quite recently the remarkable early forcing qualities had been discovered. It had broad, large flower heads and large bells of a clear blue colour; the spike was rather short.

La Victoire, which was represented in several collections in the Hall, was not fit for so early forcing, but forced very easily in the middle of January. Brilliant had long, red flower heads, large elegant bells and strong spike. Queen of the Pinks was a sport from King of the Blues, and had exactly the same character and properties, except for the colour, which was a bright rosy pink. King of Violets, with lilac-violet bells, and Ivanhoe, black-blue, very much admired in the Hall, were two other sports from King of the Blues. King of the Blues being a rather late flowering variety, the new forms could not be expected to be fit for earliest forcing. Nevertheless, they were most promising acquisitions. Rose Lord Balfour was a sport which had not yet received an appropriate name. Lord Balfour was

well known by its fleshy, large bells and its particular colour. The rose-coloured sport might be compared with a very bright and clear Moreno as far as colour was concerned. It was an excellent early-forcing variety.

White Lady was the pure white form of the blue Lord Derby, a well-known large flowering variety with a strong spike. The sport was of a satiny white. It had been known for several years, and was now becoming very popular. Lady Borell was a sport from Lady Derby, and had a deeper and more vivid colour. Dr. Lieber was an improved Charles Dickens, which it resembled in many respects. It was an excellent, early-forcing variety. Cardinal Manning was bright scarlet, and a worthy companion to La Victoire, but was better suited for early forcing. A fine flower head on a spike of medium length. Marconi might be called Cardinal Wiseman Improved. It had the same character, but in larger dimensions. The flower head was immense, broad and bold, with bells of medium size. There were some fine specimens in the Bulb Show. Louis Pasteur, which was also in the Hall, suggested more or less the colour of a Lilac. It had a long, dense flower head, and a very fine spike. It was pretty early, and a good forcing variety. Prince Henry, rosy-white, large flower head, with fine bells, had a very good spike. Princess Juliana was waxy-white, with a broad, well-formed flower head. Queen of the Netherlands was an excellent pink in the same style as Prince Henry. The three latter varieties were very little known, but they were all highly promising. The newest additions to the list were Purity, with large flowers and fleshy bells of a creamy-white colour, Parsifal, with large lilac-blue flowers, and Count Zeppelin, a soft lilac sport from Grand Maître. Purity, Parsifal, and Count Zeppelin recently obtained the First-class Certificate of the Dutch Bulb Growers' Society.

Mr. Guldemond followed with a speech in which he said that thirty years ago Hyacinths were harvested—or, as it was termed in his country, lifted—between June 15 and June 23. They were then laid in rows on the ground and slightly covered with sand. After six or seven days they were brought into the warehouses, the work being usually finished about July 5. After being properly dried, the bulbs were cleaned, sorted, and made ready for export. It would be noticed that by this treatment the Hyacinth had a considerable rest between lifting and shipping. That rest was very necessary, as during that time the bud of the new flower matured. It had been known for many years that if the weather was warm and dry directly after lifting, the Hyacinth came into bloom earlier than in those years when the temperature was cooler, which showed that the flower inside the bulb matured quicker in the higher temperature. Until a few years ago they were absolutely dependent upon weather conditions. In very wet seasons some growers, in order to dry their bulbs, found it necessary to raise the temperature in their warehouses. That was done by means of big stoves. It was noticed that the bulbs stored nearest to the fire gave the best blooms and flowered earlier than those in a cooler place. That was a point of great importance to understand, for it had enabled them to meet the ever-increasing demand for early bulbs. Stoves were soon discarded in favour of the hot-water heating system, which gave a more even temperature and could be better controlled. Nearly all the leading firms and growers were working in this direction, and had obtained results never before thought of. As an example, one grower was able on December 23, 1910, to have about 2,000 Hyacinths in flower, nearly all of which were very good. Since 1911 the General Association of Dutch Bulb Growers had held their annual show of early-flowering bulbs, and the improved results from year to year were most interesting. Up to now it had been necessary to send these Hyacinths, which were required to be in bloom at or before Christmas, to France for one year's cultivation; but the time was not far distant when Dutch growers would be able to sell and guarantee Dutch prepared Hyacinths to flower at Christmas. Dutch growers, on the whole, were very modest people, and were content with a few pence profit; but although they wished their friends in France every prosperity, they

thought they should like the whole shilling! The Dutch Government, knowing the national importance of the bulb-growing industry, had founded a special school, where young men could be trained in the business.

The Rev. G. H. Engleheart said he was once much engaged in raising the Daffodil, and it gave him great pleasure to see so many of his children represented at the show.

Mr. Wentholt said the relationship between Englishmen and Dutchmen and bulbs was not a relationship of mere money, but of common love for the flowers.

Mr. A. Worsley said if they looked back thirty years they would see a tendency to cultivate a few sections of bulbs at the expense of all the others. They had to study the desire of amateurs for new things and for greater variety.

Mr. Jan de Graaff suggested that the R.H.S. should reserve the middle of the hall for the bulbs in order that they could be shown on the ground.

Among the other speakers were Messrs. Walter T. Ware, Van de Meer, John Hoog and A. Byvoet.

ROYAL DUBLIN.

TREES AND THEIR VARIETIES.

MARCH 6.—Professor A. HENRY, in a lecture entitled "Trees and their Varieties," at the Royal Dublin Society on the above date, began by referring to the difficulty of defining the word species, a task which Darwin had apparently not attempted. Nevertheless, species do occur, most of which in Nature are well defined, at any rate as regards their habitat. Of common trees, pairs of species in the same country can often be readily recognised, one adapted to a dry, the other to a moist situation. Examples of this occur in the two species of Elm, of Oak, and of Birch. The Austrian Pine differs mainly from the Corsican Pine in retaining its leaves a year longer, and is thus enabled by its dense and copious foliage to keep some moisture in the dry limestone rock on which it grows naturally in Servia. The lecturer described the nature of sports, each of which arises as a solitary and often inexplicable phenomenon, either as a rare seedling or as a single branch with some strange peculiarity on an otherwise normal individual. Numerous slides showed different kinds of sports in trees, weeping and erect forms, varieties with bizarre foliage (coloured, puckered, deeply-cut leaves), dwarfs, and trees with all the branches curved and twisted. Some of these varieties, as the simple-leaf Ash and the Irish Yew, can be explained as individuals that have retained the features of the young seedling, and have never taken on the adult form, which, as a rule, differs materially from that of early youth. A good specimen of the fine Irish Yew at Seaford, Co. Down, was contrasted with the wide-spreading common Yew at Crom Castle, Fermanagh, under whose shade two hundred people had sat together at dinner.

Professor HENRY next dealt with another class of trees, those which originated by hybridisation, and he showed how, amidst innumerable varieties of Hollies, the two classes of sports and hybrids can be clearly distinguished. Hybrids, especially those of the first generation, usually show exceptional vigour. In the United States, when two kinds of Maize, one producing 42 bushels and the other 17 bushels per acre, had been crossed, their progeny gave no less than 127 bushels. First-cross trees had hitherto only been obtained by accident, as when two allied species stood together in the forest or in the nursery, and had given risen to a chance hybrid seedling. To such haphazard seedlings, picked up by observant nurserymen, we owe many valuable trees, such as the Huntingdon Elm, the black Italian Poplar, the cricket bat Willow, and the common Lime. One of them, Populus robusta, found in a nursery at Metz, has actually attained in fourteen years on the poor soil at Glasnevin a height of 45 feet. Professor HENRY has during the last three years been making crosses of Ash, Alder, and Poplar, some of which are of remarkable vigour and beauty. The manner in which the different characters of each parent combined in the offspring was well exemplified in the case of the seedlings of the Huntingdon Elm, raised by Professor HENRY, which followed Mendelian laws.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending March 14, is furnished from the Meteorological Office:—

WEEKLY REMARKS. *March 17, 1914.*

Pressure, Wind, and Weather.—Throughout the week the distribution of atmospheric pressure was of a very unsettled type. At first anticyclones ruled over Southern Europe on the one side, and from Greenland to Spitzbergen on the other. Subsequently the southern anticyclone became more extensive, stretching from the middle belt of the Atlantic to Southern and Central Europe, a new high pressure forming over Scandinavia, and the Arctic one disappearing beyond the field of observation. These anticyclones hemmed in a great basin of low pressure, embracing the British Isles, the northern half of the Atlantic and surrounding regions. Within this basin there were numerous secondary depressions, many of which, moving along paths between east and north, visited this country. As a rule, they were of no great depth, the barometer descending to about 1,000 millibars, but on the 14th a deeper one arrived over the North of Ireland, with the barometer down to 975 millibars, the system later moving northward across Scotland. With so many disturbances, the winds varied a good deal in direction, south-westerly to north-westerly predominating, and only occasionally was there a strong breeze experienced locally, but the arrival of the more intense depression near the close of the period was marked by exceedingly stormy conditions over a great part of the Kingdom, a strong gale to storm force being felt in several southern districts, with gusts of hurricane violence, 77 miles per hour at Holyhead, and 78 miles at Scilly. Rain was of daily occurrence over a wide area, and snow or hail at times. Generally the daily falls were not large, there being few instances of more than an inch, but the aggregate totals for the week were far in excess of the normal in nearly all districts, more than five times the usual quantity in England E., and more than four times in England S.E. Thunderstorms, or thunder or lightning alone, visited various parts of England and Ireland on the 9th, 10th, and 14th.

THE WEATHER IN WEST HERTS.

Week ending March 18, 1914.

Eleven Days of Very Wet Weather.—Another warm week, and the seventh in succession. During the course of it there did not occur a single unseasonably cold day or night. On the first day (12th inst.) the temperature in the thermometer screen rose to 58°, making this the warmest day as yet of the present year. The ground is now 2° warmer at 2 feet deep, and 1° warmer at 1 foot deep, than is seasonable. Rain fell on each day of the week, and to the total depth of 1½ inches. In fact, rain has fallen on all but one of the last seven days, the total measurement being 3¼ inches, which is 1½ inches more than the average rainfall for the whole month. Of that quantity 13½ gallons have come through the bare soil percolation gauge, and 12½ gallons through that on which short grass is growing, or nearly the whole of the rainfall. Both gauges are a yard square, and nearly a yard deep. The sun shone on an average for 3½ hours a day, which is a quarter of an hour a day short of the mean duration for the same period in March. On the sunniest day the sun was shining brightly for 8½ hours. The winds were as a rule rather high, and in the windiest hour, the hour ending 11 a.m. on the 16th, the mean velocity reached twenty-four miles—direction W.N.W. The average amount of moisture in the air at 3 o'clock in the afternoon exceeded a seasonable quantity for that hour by 2 per cent. An Early Rivers Peach growing on a south wall in my garden came first into blossom on the 17th inst., or five days earlier than its average date for the previous twenty-eight years, but three days later than last year. E. M., Rosebank, Berkhamsted, March 18, 1914.

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

- Mr. J. E. Jones, for 2½ years Gardener at Parnoor, Henley-on-Thames, as Gardener to Col. C. E. WUKER, Burnthwaite, Heaton, Bolton, Lancashire.
- Mr. Page, late of The Grange, Earls Barton, Northampton, as Gardener to Mrs. RENTON, Arthingworth Hall, Market Harborough.
- Mr. Ed. Hayton, for 11 years Gardener to Captain HARCOURT WOOD, as Gardener to W. H. AKROYD, Esq., Cliffe Hill, Lightcliffe, near Halifax.
- Mr. James Machar, for the past 2 years Gardener to Sir WILLIAM EDEN, Bart., of Windlestone, Ferryhill, Durham, as Gardener to Colonel ROWLAND BURDON, of The Castle, Castle Eden, Co. Durham. [Thanks for 2s. for R.G.O.F. box.—EDS.]
- Mr. Harry Winter, for the past 3 years Foreman at Gallowhill Hall, Morpeth, as Gardener to F. RICHMOND BROWN, Esq., Llanfair, Carnarvon, North Wales.
- Mr. F. Dalton, for the past 5½ years Gardener to the Earl of DUNRAVEN, K.P., at Kenry House, Kingston Hill, Surrey, as Gardener to the same gentleman at Adare Manor, Adare, Co. Limerick, Ireland. [Thanks for 1s. for R.G.O.F. box.—EDS.]

MARKETS.

COVENT GARDEN, March 18.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report.—EDS.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices. Columns include item names (e.g., Arums, Azalea, Camellias) and prices in s.d. and s.d. s.d. formats.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and their prices. Columns include item names (e.g., Adiantum Fern, Agrostis) and prices in s.d. and s.d. s.d. formats.

French Flowers.

Table listing French flowers and their prices. Columns include item names (e.g., Anemones, Daffodils) and prices in s.d. and s.d. s.d. formats.

Guernsey and Scilly Flowers.

Table listing Guernsey and Scilly flowers and their prices. Columns include item names (e.g., Anemone fulgens, Daffodils) and prices in s.d. and s.d. s.d. formats.

REMARKS.—Business is very slack, due no doubt to the unfavourable weather. Flowers from Guernsey and Scilly are still arriving in large quantities, their prices so far are very low. Some of the subjects show signs of the end of the season, and although these will be cleared very cheaply, the value of better kinds should advance. There is an abundant supply of red Roses, such as Richmond and General Jacqueminot. A few good blooms of Liberty are on sale, but they are not very plentiful. Flowers of Mme. Abel Chateau are also commencing to arrive, and these, like Niphetos, are very fine just now. Other varieties available are Prince de Bulgarie, Lady Hillingdon, Sunrise, Sunburst, Caroline Testout, Bridesmaid, Madame Hoste, Lady Roberts, and Maryland. There is still a good

supply of Carnations, but the blooms are not of very good quality. There is a good supply of Lillium Harrisii, but L. speciosum rubrum and L. s. album are not plentiful. Lily-of-the-Valley continues to be very cheap. There is an abundant supply of double and single Tulips; also Darwin varieties. A few bunches of Spanish Iris sell well at high prices. Violets are arriving in a good condition. Foreign flowers in most cases suffer from the long journey, but Stocks and Star of Bethlehem are arriving in a good condition. Parma Violets are arriving in fair condition, but the single varieties do not pay for their carriage. Trade in the plant market is only moderate. Azaleas are finishing. Cinerarias, Genistas and White Spiraeas are required most. Ferns are becoming more plentiful, but only better weather will bring about a further improvement in the trade for these plants.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various plants in pots and their prices. Columns include item names (e.g., Aralia Sieboldii, Arancaria excelsa) and prices in s.d. and s.d. s.d. formats.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices. Columns include item names (e.g., Apples, Lemons, Peaches) and prices in s.d. and s.d. s.d. formats.

REMARKS.—Of Apples Californian Newtown Pippin and a few fruits from Wenatchee of the varieties Spitzenberg and Winesap are still available. There are also Winter Nelsa Pears from California. Gros Colmar Grapes from English and Continental growers are fairly plentiful for the season. The crop of Black Alicante finished this week. Forced Strawberries are obtainable in much larger quantities, both in punnets and in boxes. About 25,000 packages of fruits have arrived from Cape Colony per s.s. "Balmoral Castle," including White, Black, and Red Grapes, Melons, Pears and Plums. Shipments of Australasian Apples are now due. Fine samples of Continental-grown Asparagus are obtainable. Supplies of Peas, Beans and Potatoes from Guernsey show an increase, but there are fewer Beans from Madeira. Good Tomatoes are arriving from the Canary Islands. Of Seakale there is a good supply and Mushrooms are plentiful. Broccoli and Early Cabbages are arriving in large quantities from all sources. Rhubarb is plentiful, and there are good supplies of Cucumbers.—E. H. R., Covent Garden, March 18, 1914.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices. Columns include item names (e.g., Artichokes, Asparagus, Carrots) and prices in s.d. and s.d. s.d. formats.

Potatoes

Table listing various potato varieties and their prices. Columns include item names (e.g., Bedford, Blacklands) and prices in s.d. and s.d. s.d. formats.

REMARKS.—Trade is slightly better, and with stocks much lower prices should show a slight increase.—Edward J. Newborn, Covent Garden and St. Pancras, March 18, 1914.

TRADE NOTES.

MESSRS. H. B. MAY AND SONS.

Mr. T. A. BARNETT, who for many years has been in charge of the order department at Messrs. James Veitch and Sons, Ltd., The Royal Exotic Nursery, Chelsea, is joining the staff of Messrs. H. B. May and Sons, Ltd., of Upper Edmonton and Chingford, and will enter upon his new duties early in April.

MR. GEO. W. HAGON.

Mr. GEO. W. HAGON, recently in the employ of Messrs. Wm. Wood and Son, Ltd., has been appointed agent in the Midland Counties and North Wales for Messrs. H. Scott and Sons, Horticultural Sundriesmen, Woodside, London.

Obituary.

JOHN C. GOULD. — We deeply regret to record the death of Mr. John C. Gould, a director of Messrs. Charles Sharpe and Co., Ltd., Sleaford. Mr. Gould, who died on the 14th inst., was for sixty-four years connected with the firm of John Sharpe, John and Charles Sharpe, and Charles Sharpe and Co. He retired from active work in the management of the business in June, 1913. The funeral took place on Wednesday last at Quarrington, near Sleaford.

STEPHEN McHALE.—Horticulture announces the death from pneumonia of Mr. Stephen McHale, foreman for John Condon, florist, Brooklyn, N.Y., on February 18. He was a native of Castle Bar, County Mayo, Ireland, and was thirty-four years of age.

DR. W. W. BAILEY. The death is recorded of Dr. W. W. Bailey, the distinguished American botanist, who was professor of botany at Brown University, Rhode Island, from 1881 to 1906. He was the author of numerous scientific works, including Botanical Collector's Handbook, Among Rhode Island Wild Flowers, Botanical Note Book, New England Wild Flowers, and Botany.

EUGENE VALLERAND.—This well-known French nurseryman, whose establishment was near Paris, died recently at Taverny (Seine et Oise), at the age of 78 years. He was a member of the National Horticultural Society of France, and an Officer of Mérite Agricole. Visitors to the Paris flower shows will remember that for many years his displays of tuberous-rooted Begonias formed a conspicuous feature of the exhibitions. The business will be carried on by his sons, Messrs. Gaston and Albert Vallerand.

CARNATIONS: *Carnation Soil.* There is no fungus present. The injury is probably caused by the soil, but what the latter contains cannot be determined now.

CUCUMBERS: *T. C.* Seeing that you have taken the precaution to cleanse the house thoroughly and limewash the walls, you might be successful this season, although it would be better to select a fresh house. Remove every particle of the old soil and scrub the wood-work, etc., with warm water with which a little carbolic acid has been mixed. Take the precaution to spray the plants at intervals with liver of sulphur, $\frac{1}{2}$ oz. to two gallons of water, and do not wait until the disease appears. Liver of sulphur has the effect of turning white paint black. Therefore, have due regard to this when syringing.

FLOWERING PLANTS FOR A LONDON GARDEN: *A. G. W. S.* The following is a list of plants, including Roses, that will do well in a London garden:—Roses (*Hybrid Teas*): Caroline Testout, Earl of Warwick, General McArthur, Grace Darling, Koenigin Carola, Lady Ashtown, Madame Abel Chatenay, Souvenir du President Carnot. *Climbing H.T.'s:* Climbing Caroline Testout, Gruss an Teplitz, Longworth Rambler. *Hybrid Perpetuals:* Abel Carrière, Frau Karl Druschki, Hugh Dickson, Margaret Dickson, Prince Camille de Rohan, Général Jacqueminot, Mrs. John Laing, Ulrich Brunner. *Climbing:* Maharajah, Mrs. W. Paul, Zepherine Drouhin, Fellenberg, Aimée Vibert, Alister Stella Grey, Lamarque, Madame Alfred Carrère, Cramoisi Supérieure, A'beric Barbier, Dorothy Perkins, Lady Gay, Paul Transon, Hiawatha, Jersey Beauty, Dawson Rose, Crimson Rambler, Conrad Meyer, and Penzance Briars. Hardy herbaceous plants that may be expected to do well are: Agrimonia Eupatoria, Anchuca italica Opal and Dropmore varieties, Aquilegia chrysantha and its hybrids, Arabis albidia fl. pl., Artemisia tanacetifolia rubra, Asters (perennial), Alpine and border Auriculas, Betonica grandiflora rosea, Campanula alliariaefolia, C. caespitosa and its variety alba, C. carpatia and its varieties alba, Isobel and White Star; C. celtidifolia, C. gargarica compacta, C. glomerata, C. Hendersonii, C. isophylla, C. latifolia, C. linifolia, C. macrophylla, C. pelviformis, C. Portenschlagiana, C. Raineri, C. rotundifolia, C. Rapunculus, C. Stansfieldi, C. Tommasiniana, Centaurea montana, Centranthus rubra, Chrysanthemum maximum, C. uliginosum, Chrysogonum virginianum, Cimicifuga racemosa, C. simplex, Coreopsis lanceolata major, C. verticillata, Corydalis thalictrifolia, Delphiniums of garden sorts, Alpine and border Dianthus, Dictamnus fraxinella, Digitalis purpurea and alba, Doronicum Caucasicum, D. Clowesii, Epilobium angustifolium, E. a. album, E. obcordatum, Epimedium pinnatum, E. niveum, Erigeron aurantiaceum, E. Quakeress, E. speciosum, E. mucronatum, Ervsum Arkanosanum, E. helveticum, Funkia subcordata and varieties, Gaillardia hybrids, Galega officinalis varieties alba, bicolor, and Hartlandii; Geranium Endresse, G. ibericum platyphyllum, G. macrorrhizum, Geums Apricote, Mrs. Bradshaw, and Heldreichii lutea, Helenium autumnale, H. Hoopesii, Helianthus

multiflorus fl. pl., Hemerocallis aurantiaca major, H. Middendorffii and others, Heuchera gracellina and hybrids, Inula glandulosa, Isatis glauca, Kniphofia Aloides and varieties, Liliums in variety, Lupinus polyphyllus of sorts, Lychnis Chalcedonica, L. viscaria, Lythrum alatum, L. salicaria, L. s. roseum, Lysimachia clethroides, L. s. thyriflora, Monarda didyma, Nepeta Mussinii, Oenothera Youngii, O. Fraseri, Papaver orientalis, Alpine and border Phloxes of sorts, Polemonium coeruleum and varieties, Potentillas in many varieties, Primula denticulata, P. frondosa, P. cashmeriana, P. pulverulenta, P. japonica, P. denticulata, P. Beesiana, P. Bulleyana, P. capitata, P. Forrestii, P. Poissonii, Pyrethrums, Rudbeckia laciniata fl. pl., Salvia virgata, Saponaria officinalis, Solidago Shortii, S. Virgaurea, Thalictrum adiantifolium, T. atropurpureum, T. aquilegifolium, Trollius europaeus (Orange Globe and Fire Globe), Verbascum Chaixii, V. olympicum, and Violas. Suitable annuals include: Double and single Chinese Asters, Antirrhinum, Calliopsis, Celandula, Candytuft, Centaurea, single and double Clarkias, Convolvulus, Dianthus chinensis, Eschscholtzia, Godetia, Helianthus, Larkspurs, Lavatera trimestris, Lupinus, Marigolds, Mignonette, Poppies, Hesperis matronalis (Rocket), Stocks, Sweet Peas, Wallflowers, Zinnia elegans and Nigella Miss Jekyll.

GARDENIA LEAVES: *C. H.* We cannot tell you the cause of your Gardenia leaves turning yellow, for there is no disease present due to fungi. The injury is probably caused by unsuitable soil.

KENTIA FORSTERIANA.—*G. H. H. W.* Our market expert informs us that there is only a limited demand for large Palms, and that the value of your specimen would be approximately 25s. to 30s.

MINT DISEASED: *C. H. E.* The Mint is attacked by the Mint rust (*Puccinia menthae*) which often destroys entire beds of Mint. Dig up the infected plants, burn them, and be careful to remove all underground portions of diseased plants. Plants from infected beds even if they do not show signs of disease should not be used for making new beds, for they are likely to be infected with spores from diseased plants. The wild Mints are often badly diseased, and the disease may be introduced to cultivated Mint if hay or other litter containing diseased wild Mint in a dried condition is brought in contact with the cultivated Mint.

MOSS ON LAWNS: *Anxious.* First give the turf a raking with an iron rake to remove as much of the moss as possible. Let this be done thoroughly, working across as well as up and down the lawn. Next sweep the turf and then apply superphosphate at the rate of 2 oz. to the square yard. Green vitriol (ferrous sulphate) applied at the rate of $\frac{1}{2}$ cwt. to 2 cwt. per acre is also effective in destroying moss on lawns. It is necessary in some cases to repeat the dose. Other substances which are valuable for eradicating moss on lawns are copper 2 per cent. and nitrate of soda 10 per cent.; these should be mixed and sprayed on the turf at the rate of about 70 gallons per acre. The advantage of liming mossy land is well known. The dressing you suggest would benefit the grass.

NAMES OF FRUITS: *D. M. H.* Apple Annie Elizabeth.

NAMES OF PLANTS: *E. S.* Pinus sylvestris aurea.—*H. B. 1.* Gazania sp., probably splendens; 2, not recognised, send when in flower.—*C. E. 1.* Laelia-Cattleya Gottoiana; 2, Laelia cinnabarina.—*M. P.* Eulophia lurida.—*F. T. 1.* Asplenium lucidum; 2, A. marinum; 3, Adiantum hispidulum; 4, Selaginella uncinata.—*Ecclcs.* 1, Cypripedium villosum; 2, Cypripedium Boxallii atratum; 3, Cypripedium Haynaldianum; 4, Cypripedium Boxallii; 5, Laelia-Cattleya Warnhamensis (L. cinnabarina \times C. Trianae).

PEST OF CYCLAMEN: *E. P. D.* Black weevils are destroying your Cyclamen plants. Bisulphide of carbon or "Vaporite" may be em-

ployed for destroying the grubs that are below the surface of the soil, but there are various ways of trapping the beetles. As they feed chiefly by night, and have the habit, like most other weevils, of dropping to the ground on being suddenly disturbed, it is desirable to group the plants together during the day, standing them on a large, greased sheet of white paper or calico. After this has been done enter the house at night-time with a bright light, and tap the pots or shake the plants whilst holding them to one side, when the weevils will fall on the sticky surface, and may be caught easily. Another method is to trap them with pieces of some vegetable, such as Potato or Carrot.

QUINCE NOT FRUITING: *H. J. G.* You must exercise patience. The tree has only been planted two years, and it is not unusual for fruit trees to fail to fruit in such a short period after planting. We have had the same experience with a Pear tree planted three years ago. As your plant has bloomed freely it will perhaps satisfy your expectations this season, as we are hoping the Pear will ours.

ROSCOEIA: *Miss B. Shaw.* Your plant is probably Roscoea purpurea, which is half-hardy in this country. You have evidently been growing the specimen in too hot and moist conditions. The plant is deciduous, dying down each autumn with the early frosts. It is best planted out in a warm, sunny situation in April in a rich, open compost, such as you have previously used, placing the tuberous root-stock about 2 inches below the surface. The flowers are produced from July to September, and are of a rich purple colour. Lift the tuberous root-stocks in the first week of October, and store them in a box of dry sand in a cool, dry, frost-proof room until the following spring. Treated in this way, the plants will increase rapidly.

SEEDS OF DOGWOOD POISONOUS: *Alex. E. Beaton.* There does not appear to be any well-founded reason for believing that the berries or seeds of various kinds of Dogwoods, or Cornus species, are poisonous to birds. Various Cornuses are widely planted throughout the country, and one or two species grow wild, yet we have been unable to trace any reference to the fruits being poisonous to birds. As a rule birds are very careful to avoid fruits of a poisonous nature, and there is no reason why you should not proceed with the planting of Red Dogwood as undergrowth in woods and plantations.

SEEDS USED FOR ROSARIES: *W. T. Price.* The seeds of Sapindus Saponaria, a small tree belonging to Tropical America and the West Indies, are frequently used as beads and made into rosaries. They are hard, black, and take a good polish, and in addition to their use as beads, they are also employed for making buttons. The seeds of other plants are also used for beads, notably those of Toddalia sp., Calodendron capensis and Abrus precatorius. The seed of the last-named is bright red with a single black spot. The seeds are often called Crab's Eyes and Rosary Peas, and the plant is sometimes known as the Rosary Bush. The first-named is, however, the most important seed used for the purpose.

PRIMULAS: *E. H.* No fungus is present. The silvery appearance suggests injury caused by fumes.

TOMATOS DISEASED: *W. C., Taplow.* Yes, the disease attacking your plants is the sleeping disease. Soak the soil with a solution of sulphate of potash, 1 oz. in 2 gallons of water, repeating the operation after six days.

"THE HORTICULTURAL RECORD"*

(See Coloured Supplement.)

THIS stately volume dedicated to his most gracious Majesty King George V. is a memorial of the great International Exhibition of 1912. In this record the Chelsea show lives again. As we turn its pages we see once more the long and busy avenue, the great tent, and feel the press of the throng making its way to the Rock Gardens or the Orchids. It accomplishes more than this. For not only does the Record rekindle our enthusiasm for the magnificent cultivation which was demonstrated at the Exhibition, it also brings within the compass of the mind the large part which the Exhibition was destined to play in influencing the art of gardening. Indeed, it is no exaggeration to say that the in-

fluences which spread from Chelsea are to-day making themselves felt and seen in most of the gardens in this country and in many of the gardens of foreign countries.

Without this generous enterprise on the part of Mr. Cory, in course of time—our memories growing old—we should have forgotten the skill and labour and devotion bestowed upon the Exhibition, and the show itself, like an insubstantial pageant faded, would have left not a rack behind. Now, instead of searching through the dusty archives of the past and reconstituting the show from a study of laconic official documents, the horticulturist of the future may himself see the Exhibition and share our own vivid enjoyment of that event.

Albeit that this work is justly entitled a Record, it is more than that. For Mr. Cory has summoned to his aid a distinguished band of horticulturists, who have traced the several histories of the chief groups of plants from 1866, the days of the former International Exhibition, to the present time. These essays, all of remarkably high merit, constitute the first 178 pages of the volume, and serve to focus attention on the salient features of the show.

It is but proper that the first of these historical résumés should be devoted to Garden Design and Rock Gardens; for it is not to be denied that the excellent garden exhibits at Chelsea have had far-reaching influence. It needs only to read the first page of this brilliant contribution to discover in its nervous, incisive, provoking prose and in its wealth of information the hand of Reginald Farrer. Therein he projects one of his apocalyptic visions on paper, and stricken dumb with its effulgence we have revealed to us the whole art and meaning of the rock garden.

The tumult and the shouting dies as we turn to the more peaceful pages and follow the serener guidance of Mr. H. R. Darlington, with whom it is Roses, Roses all the way. We trace the vicissitudes of this flower from 1866 to the present day, learn of the decadence of the Hybrid Chinas, the fall of the Bourbons, and the decline of the Hybrid Perpetuals. The census of Roses shown at the 1866 Exhibition is profoundly interesting, and this chapter in history will prove invaluable to all students and lovers of the flower. Mr. W. J. Bean, never so happy as when he is among trees and shrubs, treats of these garden subjects, and shows what a wealth of new plants the gardener of to-day has at his command, as compared with his predecessor of 1866. Since that date Fortune, Veitch, Maries, and Wilson have brought home trees and shrubs from the East and West, and have added enormously to the resources of the modern gardener.

Mr. William Watson's essay on tropical plants takes our minds back to the days when these nurslings of the hothouse were prime favourites in the garden. Mr. James O'Brien's paper on Orchids is all that we should expect from one whose knowledge of the garden history of these plants is unrivalled.

Mr. Cuthbertson treats of Sweet Peas, Mr. C. H. Curtis (Greenhouse plants), Mr. Charles T. Druery (Ferns), Mr. E. A. Bunyard (Fruit), and Mr. G. F. Tinley (Vegetables).

Part II. of the volume consists of a detailed record of the show, accounts of the various arrangements, and reports of the speeches delivered during the various functions held in the course of the exhibition. Next follow the report on Horticultural Education, prepared by Mr. Chittenden for the Science and Education Committee, and a full account of the Conference. The report on Legislation in connection with plant diseases occupies nearly 100 pages, and the letterpress concludes with a list of the Jury and an enumeration of the awards. No less remarkable than the text is the series of coloured plates appended to the volume.

To have obtained the photographs during the short time that the subjects were in their best condition was a feat of no ordinary magnitude, and that the results should have reached so high a standard is a tribute to the pains taken with them. There will doubtless be critics who will comment adversely on the lack of depth and brilliance in some of the colour pictures, but no one who has experience of the difficult art of reproduction in colour will be grudging of praise for the general results. We reproduce in the Supplement one of the plates, which gives a very good illustration of the Japanese garden designed by Messrs. J. Carter and Co., Raynes Park. Amongst the others some of the more striking and successful are "Phalaenopsis, Dendrobiums, and Cypripediums"; "Cypripedium Maudiae"; "Anthuriums from Italy"; "Begonia Victoria Louise"; "Hippeastrum Daphne"; "H. Holfordii"; "Schizanthus retusus"; "Roses, Carnations, and other Flowering Plants"; "A Rose Garden"; "Japanese Garden Ornaments"; "Water Garden with Wistarias and Clematis Lord Neville." Of all the pictures that which pleases us for its artistic effect most is the beautiful scene "Rock Garden with Bamboos." The black-and-white illustrations, 71 in number, are of a high standard of excellence, and conspicuous among them are *Drosera binata* and a group of Australian Pitcher Plants.

It may well be that the glory of the garden abideth not in words, and it may be also that that glory is reflected neither by coloured nor black-and-white photographs. Nevertheless, to those whose imaginations are aided by printed word and pictured scene this richly illustrated and finely-compiled book will appeal with insistent force. It shows the strength of British Horticulture, it brings gracious memories. For those who care for these things admiration will brighten any tints which may be dull and knowledge will correct such tones as are false.

The heavy task of editing the Record has fallen to Mr. R. Hooper Pearson. We congratulate the editor and contributors, and we wish Mr. Reginald Cory's enterprise the success which it so richly deserves. K.

NEW OR NOTEWORTHY PLANTS.

SOME NEW SHRUBBY SPECIES OF AMERICAN HAWTHORNS.

THE Intricatae Group of North American Crataegi are widely distributed. Several species are found in Ontario, Canada, and a considerable number in New York State. Pennsylvania seems to be the headquarters of the group, where thirty-three species have been discovered. They are found sparingly through the southern states, and a number of species have been described south-westwards across the Mississippi in Missouri.

The group characters are well defined. The leaves are membranaceous, and generally cuneate at the base, and often distinguished by a concavity of surface; petioles short, glandular; flowers large, opening late, in few-

1½ inches long and 1¼ inches wide; petioles slender, wing-margined above. The 10-stamened, cream-white anthered flowers come into bloom about the last of May. The oblong obovate drooping clusters of fruit when fully ripe assume a light red to yellowish bronze colour, and ripen towards the middle of October. The type plant grows on Brandywine Creek, near Wilmington, Delaware. The species has been found distributed through Pennsylvania.

C. CORNELLII, Sargent.—This hawthorn is a low-growing shrub and seldom exceeds 4 to 5 feet in height. The branches are erect, forming a narrow head. The leaves are oval, acuminate at the apex, abruptly cuneate at the base, with 4 to 5 pairs of small acuminate lateral lobes, 2 inches long and 1½ inch wide; petioles slender, wing-margined at the apex. The corymbs, with 10-stamened flowers and cream-white anthers, blossom during the first

September. The fruits are borne on dense, large clusters, and when fully ripe drop with the slightest shake. This is a noticeable feature when collecting the fruits either for the herbarium or for sowing. The type plant grows on a roadside on the north side of Toronto, Ontario, Canada, and has not yet been reported outside of that region. It is named in compliment to the late Delos Whie Beadle, a well-known nurseryman, pomologist, and botanist, in Ontario, Canada, who did excellent work in studying the rich fields of Crataegi in different parts of Ontario.

C. FLAVIDA, Sargent.—This species is an intricately branched shrub 8 to 9 feet tall, with a wide, dense head. The leaves are oblong-obovate, acute at the apex, concave cuneate at the base, divided above the middle into three to four pairs of small acute lobes, 1½ inch long and 1¼ inch wide; petioles slender, narrowly wing-margined at the apex. The 5 to 8-stamened flowers, with

FIG. 95.—CRATAEGUS FOETIDA GROWING SPONTANEOUSLY IN SENECA PARK, ROCHESTER, U.S.A.

flowered glandular corymbs, with large conspicuous bracts and bractlets, and in the large majority of the species usually glabrous; stamens rarely more than ten, usually creamy-white, occasionally pink or rose; fruit ripening late, in varying shades of brownish red to yellowish red.

None of the species in the group attains the dimensions of small trees, and they are mostly of neat, compact habit. The showy flowers in spring, with handsome fruit displays in the fall, and the highly-coloured foliage that many of them assume, render them charming plants for garden and park decoration. Dr. C. S. Sargent, Director of the Arnold Arboretum, Harvard University, has a high appreciation of their decorative value.

The following described species are in the Intricatae Group:—

CRATAEGUS APOSITA, Sargent.—This species attains a height of 6 to 8 feet, with a thin branching habit, and slender spreading branches. The leaves are oblong to oval, acute or rarely rounded at the apex, cuneate at the base, slightly and irregularly lobed towards the apex,

week in June. The obovate fruits, rounded at the apex, red to orange-yellow, suspended on the short, stout pedicels, ripen about the end of September. The type plant grows on a moist hillside at Coopers Plains, Steuben Co., in Western New York. The species is named in compliment to G. D. Cornell, an industrious school teacher, who made a thorough study of the Crataegi in his home county. At the present this species has not been reported outside of this country.

C. DELOSII, Sargent.—A shrub 6 to 8 feet high with intricate branching stems, and branches generally spreading horizontally; leaves ovate, acuminate at the apex with short points, concave cuneate at the base, divided into five to six pairs of acuminate lobes, 2½ inches long and 2 inches wide; petioles stout, wing-margined occasionally to the middle. The 7 to 10-stamened flowers on large corymbs (unusually large for the Intricatae Group), with cream-white anthers, blossom during the first week of June. The short, oblong, slightly obovate reddish-orange fruits ripen about the end of

pale yellow anthers produced on lax corymbs, blossom about June 4. The subglobose to short-oblong fruits, dull reddish-orange, ripen at the end of September. The type plant grows in an open moist wood near London, Ontario, Canada.

C. FOETIDA, Ashe (C. Baxteri, Sargent) (See fig. 95).—This is usually an arborescent shrub from 12 to 14 feet high, very intricately branched with spreading and ascending branches, forming a handsome, irregularly round-topped head. Leaves oblong-ovate to oval, acute and sometimes almost rounded at the apex, concave-cuneate to truncate at the base, divided into short, broad, acute lateral lobes, and always characterised by a conspicuous concavity of surface, 2½ inches long and 2¼ inches wide; petioles slender, somewhat wing-margined at the apex. The 10-stamened flowers, with pale yellow anthers borne on compact corymbs, blossom from June 4 to 8. The subglobose fruits, somewhat flattened at the ends, orange-red when fully ripe, and occasionally with a bronze-reddish tinge, ripen about the middle of October. The type plant grows in Seneca Park, Rochester,

N.Y. It is widely and commonly distributed through Western New York, Pennsylvania, and Ontario, Canada. This is the largest growing species in the Intricatae Group with which the writer is acquainted. The foliage turns to a handsome yellowish-red colour about the end of October. It is an extremely valuable shrub for garden decoration.

C. NEMORALIS, Sargent.—A tall shrub with a somewhat erect branching habit, from 10 to 12 feet high. Leaves usually oval in outline, acute at the apex, gradually narrowed at the base, divided above the middle into coarsely serrate acute lobes, 2 inches long and $1\frac{3}{4}$ inch wide; petioles slender and slightly grooved. The 10 stamened flowers, with pale yellow anthers produced on slender corymbs, blossom at the end of May. The subglobose to globose red fruits ripen in October. The type plant grows at Rockford Park, Wilmington, Delaware. The species is said to be common in that region in rocky soil.

C. MINUTIFLORA, Sargent.—This species is a low intricately-branching shrub, 5 to 6 feet high, and inclined to spread into thickets. The leaves are usually suborbicular and usually broader than long, acute at the apex, rounded at the base, divided above the middle into three or four pairs of broad acute lobes, 2 inches long and $2\frac{1}{2}$ inches wide; petioles slender, slightly wing-margined at the apex. The 10-stamened, pale pink anthered flowers are borne on very compact corymbs, and blossom about June 4. The short oblong to subglobose fruits, dull orange-red in colour, supported on stout, erect pedicels, ripen about the middle of September. The type plant grows in an open pasture at Bracondale, a suburb of Toronto, Ontario, Canada. This species is distinctive in this group for its small flowers.

C. MODESTA, Sargent.—A low shrub that rarely exceeds 3 to 4 feet in height. The slender branches are numerous and intricate. Leaves ovate, acute at the apex, rounded at the base, divided into numerous short lobes, 2 inches long and $1\frac{1}{4}$ inch wide; petioles slender, somewhat winged above. The 10-stamened flowers, with pale yellow anthers, are borne on compact pubescent corymbs, and blossom during the first week in June. The subglobose fruits, flattened at the ends, orange-red in colour, on erect peduncles, ripen about the end of September. The type plant grows on the rocky benches of Twin Mountain, West Rutland, Vermont. It is distributed in Eastern and Western New York and Eastern Pennsylvania. This is one of the smallest growing species of the group known to the writer, and is marked by pubescent corymbs, a specific character found in very few species in the group.

C. PECKII, Sargent.—This species is a broad-headed shrub, 5 to 6 feet tall, with numerous intricate branches. The leaves are oblong-ovate, acuminate at the apex, rounded to concave-cuneate at the base, divided into three or four pairs of slight acute lobes, 3 inches long and $2\frac{1}{2}$ inches wide; petioles stout, slightly winged-margined above. The 10-stamened flowers, with purplish-pink anthers on slightly pubescent corymbs, blossom during the first week of June. The subglobose to ovate fruits, reddish-green in colour, borne in erect clusters, ripen about the middle of October. The type plant grows at Lansingburg, near Troy, on the Hudson River, New York. So far as is known at the present time, the species is confined to a very restricted area. It is named in compliment to Professor Charles H. Peck, the distinguished State Botanist of New York, who has given a great deal of study to the genus *Crataegus*. Professor Peck is well known throughout the scientific world for his investigation and discoveries in mycology.

C. VERECUNDA, Sargent.—This is commonly an erect, branching shrub 6 to 8 feet high, but it is sometimes found in shaded conditions 3 to 4

feet tall. The very dark purple spines, markedly curving downwards, are a distinguishing feature of the species. The leaves are oblong-obovate to oval, divided above the middle into a few short, broad, acute lobes, $2\frac{1}{2}$ inches long and 2 inches wide; petioles slender, wing-margined by the decurrent bases of the leaf blades. The 5 to 7-stamened flowers, with cream-white anthers borne on thin corymbs, blossom from June 4 to 8. The oblong-obovate crimson-orange fruits, borne on slender pedicels, ripen early in October. The leaves of this species unfaithfully turn to lemon-yellow, and fall before the end of October. The type plant grows in shaded rocky woods, in the gorge of the Genesee river in Seneca Park, Rochester, New York. It was at first suspected that this species was partial to shady woods, and that it did not exceed 3 to 4 feet high. A few years since I found it growing in colonies in an open pasture near Conesus Lake, forty miles south of Rochester, N.Y., 6 to 8 feet high, and in much more vigorous habit than the type plants. The flowers and fruits, however, plainly showed the species to be *C. verecunda*. The species has during recent years been found at widely different points in New York State. *John Dunbar, Rochester, N.Y., U.S.A.*

ORCHID NOTES AND CLEANINGS.

EPI-LAELIA MEDUSAE (L. CINNABARINA × E. CILIARE).

THIS remarkable and interesting hybrid flowered in the gardens of the Right Hon. Lord Rothschild, Tring Park (gr. Mr. A. Dye), and it forms a useful subject in which to trace out the results of the struggle which Nature makes to accommodate in the offspring the characters of two such diverse parents, and the compromise which results. A curious point is that the flowers of the hybrid are larger than either parent. The red tint of *Laelia cinnabarina* appears in a modified form, but its narrow, wavy-edge lip is broadened out to fill in the spaces between the long, bristle-like filaments of the lip of the *Epidendrum*. This reduces the fimbriation considerably, but the filaments are distinctly traceable in the membrane of the labellum of the hybrid. The long filiform front lobe of the lip of *E. ciliare* well maintains its character, but is shortened and changed by a membranous wing on each side distinctly acquired from the *L. cinnabarina*. In habit the plant is intermediate between the parents, but the scape is more like the *Epidendrum*, 9 inches to 1 foot, dark green, slightly compressed, and furnished at intervals with sheaths 1 inch long, three to five flowered: pedicel and ovary 3 inches, the lower third enclosed in a sheath; sepals 2 inches long by $\frac{1}{4}$ inch wide, keeled at the back, and re-curved at the tips; petals rather shorter and narrower, slightly wavy at the margin, curved forward, both sepals and petals red on yellow ground; lip adnate to the column, three-lobed, nearly 2 inches long, the side lobes fimbriated and re-curved, white tinged with yellow outwardly, mid lobe linear for half its length, then broadening into a narrow lanceolate blade tinged with reddish-yellow and slightly fringed in the lower half. It is not recorded which of the parents bore the seed-capsule, but it was most probably *Epidendrum ciliare*. It is interesting that two species so vastly different in structure in every part should produce an offspring which is a reproduction in part of each parent.

LAELIO-CATTELEYA GOTTOIANA VEITCH'S VARIETY.

THE fine and richly-coloured variety of this natural hybrid, which, as well as being a handsome flower, is one of the best parents in the hands of the hybridist, was shown by Messrs. Jas. Veitch and Sons at the R.H.S. meeting on the 10th inst., and proves that importations

still give remarkable varieties. *Laelio-Cattleya Gotoiana* was first shown at the meeting of the Royal Horticultural Society on June 23, 1891, when the plant received a First-Class Certificate. The parentage then suggested—*C. Warneri* × *L. tenebrosa*—has since been verified. Subsequently the plant was occasionally imported with *L. tenebrosa* and *C. Warneri*, but the forms were mostly of indifferent quality though good breeders. The form shown recently by Messrs. Veitch with large, vinous-purple flowers was imported with *L. tenebrosa*, and is probably the finest yet seen.

THE ROSARY.

ROSES UNDER GLASS.

WITH increasing heat, the growth of pot Roses will become more rapid, so that watering must be attended to with care. In the case of large specimens in pots, tap the pots; those that give a clear, bell-like sound should be copiously watered. The plants showing bud will need a stimulant; a safe mixture is liquid cow manure and soot. To well-established plants this may be given twice a week until colour is seen in the buds. Damp the surfaces in the house with a little manure water to feed the foliage, but do not overdo this treatment. A little bone flour worked into the surface of the soil has a very stimulating effect on pot Roses. Guano water is also of assistance; use about a teaspoonful to one gallon of water.

Backward plants should be tied into shape, so that every leaf obtains the benefit of light and air. Do not maintain too high a temperature. Roses do not like severe forcing, excepting, perhaps, the true Teas. These, when once started, should be kept going, increasing the temperature until it reaches about 55° at night.

A buoyant atmosphere must always be maintained in the Rose house. If dryness of atmosphere is allowed red spider soon becomes troublesome. Frequent syringing should be resorted to, the syringe being directed well beneath the foliage.

Fumigate as soon as traces of green fly are observed, not waiting until large numbers appear. Auto Shreds is a good insecticide and easily used. For mildew Campbell's Vaporiser is good.

When beginning to show colour, Roses develop best in a cool temperature, so that if a north house is available move such plants into it. Roses glory in sunshine when they are growing, but all Rose houses should be equipped with roller blinds to shield the plants from fierce heat, especially in April and May. Rambler Roses grown as pot or tub plants will need much water, and it is necessary to look over them two or three times a day. They succeed best when in comparatively small pots, but if so grown they require specially frequent waterings.

A bunch of *Mme. Edouard Herriot* shown at the R.H.S. meeting on February 24 created much interest, indicating the popularity of hard colours in forcing Roses. *Melody* is being extensively grown by some commercial florists, one grower alone devoting several houses to its culture. The new American Rose *Hadley* is said to be superior to all other red varieties. *Ophelia* will be a great favourite, especially as a forcing Rose.

Now is the time to insert Rose cuttings from growths that have just flowered. These root readily in a sandy compost, the pots being plunged in the propagating frame or in a dung-bed. Such plants furnish useful material for forcing. Always insert strong, healthy cuttings and give them ample room in the cutting-pots. If space allows, one cutting inserted in a thumb-pot is better than inserting several in a pot of larger size. *Experience.*

NOTES ON TULIPS.

TULIPA KAUFMANNIANA COCCINEA.

This scarlet form of the well-known Tulipa Kaufmanniana opens its flowers in the middle of March. It is perfectly hardy, but deserves, if ever a plant did, a sheltered, sunny corner. The huge flowers are of the most brilliant scarlet with a pure yellow base, and they open in the sun as does the type. The effect of a group of a few of these Tulips is simply amazing in its splendour.

The red colour seems to pervade the whole plant, for the very leaves are red when they first appear through the ground, though they soon lose this colour; while the fact that the first small leaves of the germinating seeds are also of a bright-reddish hue seems to indicate that this fine form will come true from seed.

TULIPA LOWNEL.

THE sight of a well-flowered pot of Tulips, labelled *T. Lownei*, in the Alpine house at Kew led me recently to look up this species in the herbarium, where Mr. Baker's type specimens of the species are preserved. It became at once apparent that the plant which has been in cultivation for some years as *Tulipa Lownei* is wrongly named. The type specimens are both two-flowered and the plant looks very like a dwarf *T. saxatilis*. I failed to find in the herbarium any wild specimens of this latter species, but it would hardly be surprising if, in its native mountain habitat in Crete, the plants were very much smaller than the cultivated specimens in our gardens. Moreover, side by side with the so-called *Lownei* there were also displayed in the Alpine house some excellent examples of *Tulipa pulchella*. A careful comparison of the two revealed the fact that the only difference lay in the colour of the flowers. The dull-red flower with a blue base of *pulchella* was replaced by a pink flower with a pale-yellow base. It is true that those labelled *T. pulchella* usually had only three leaves to the four of the pseudo-*Lownei*, but these numbers were not constant. *T. pulchella* is a native of the Cilician Taurus, and, as the so-called *Lownei* bulbs are obtained from Syria, it is probable that they merely represent a local colour form of that species, and they should more properly be called *T. pulchella* var. *rosea*. Whether the real *T. Lownei* from the top of Mount Hermon is identical with *T. saxatilis* from Crete it is at present impossible to say. W. R. Dykes, *Charterhouse, Godalming*.

VEGETABLES.

ASPARAGUS.

FOR the past few years we have adopted the practice of raising annually a batch of Asparagus plants by sowing the seeds in 60-size pots, raising the seedlings in a cold frame and thinning them when quite small to one in a pot. The plants are grown in an open situation during the summer, the pots being plunged in finely-sifted cinder ashes as a protection against frosts during winter. The plants are set out early in April in well-prepared beds. This may appear a troublesome method, but I am convinced that much better results are obtained than by adopting the usual practice of sowing the seed in the open. We have cut good heads in the first year after planting and splendid produce in the second season, and I would strongly advise anyone who has not tried this plan to give it a trial.

I do not wish to take credit for this method. On visiting a fellow-gardener some years ago I was much impressed with his Asparagus, and he kindly informed me of the plan I have described, which he had practised for many years with good results.

THE HERB BORDER.

A well-arranged, properly-kept herb border is by no means the least attractive or useful part of

the kitchen garden. Although it is not possible to cultivate all things classed as herbs in all establishments, there are nevertheless many kinds which are in constant demand, and these should be included. It is essential every few years to renovate, re-plant, or re-arrange them, and now is a capital time to undertake the work.

Almost any site or aspect except a north one will suit the majority of herbs, but for preference choose a west or east border. By adding a good supply of fresh material annually the same position will answer for many years. The ground should be well trenched and enriched with well-decayed manure, leaf-mould, and the materials from spent hot-beds. If the soil is of a wet, retentive nature lighten it by adding road-grit and finely sifted mortar rubble. Perennials, biennials and annuals should be placed together, and, when it is not necessary to re-plant, a good top-dressing of suitable material should be afforded. Mint grows best in decayed leaf-mould, and Thyme (especially Lemon Thyme) delights in an annual dressing of road-grit.

The propagation of most kinds of Herbs is very simple. All the perennials may be increased readily by division or from cuttings, whilst many are easily raised from seed, as are the annuals and biennials. Certain of the stronger-growing kinds will need annual pruning to keep them within bounds. Among the most useful herbs are Bush and Sweet Basil, Borage, Chervil, Chives, Fennel, Pot Marjoram, Sweet Marjoram, Mint, Parsley, Sage, Summer and Winter Savory, Sorrel, Tarragon, Thyme and Lemon Thyme. *Edwin Beckett*.

LILIUM PARRYI.

IN the *Gardeners' Chronicle*, January 24, 1914, p. 60, Messrs. Wallace, of Colchester, quote Purdy, the Californian collector, as writing of this Lily:—"I am at last making *L. Parryi* a success. It is . . . not boggy soil that the plants need. . . . I have one fine bed of young ones that was quite dry all summer." The italics are the present writer's.

It is something of a shock to find that after all these years the arch-priest of Californian bulb culture should only now be able to say that he is making a success of this Lily, and, in the absence of further information, the fact is calculated to deter others less fortunately placed than he from attempting the cultivation of one of the fairest of wild flowers.

But our countrymen need have no qualms on the subject, for if one goes the right way to work there is no insuperable difficulty in the cultivation of *Parry's* Lily, and no one not bereft of his senses would attempt to grow it in boggy or waterlogged ground.

By no stretch of the imagination can *L. Parryi* be as yet included in the comparatively short list of Lilies which will always fend for themselves in our climate without some assistance from the gardener, and go on from season to season till waning growth points to exhausted soil and overcrowded bulbs; but if the needs of this Lily—and they are perfectly well understood—are ministered to with a modicum of the sympathetic understanding hundreds of people bestow on "difficult" garden plants, there should be no fear of the result.

Assuming that the soil conditions are right the normal English summer is good enough for *L. Parryi*: it is the exceptional season that lays it by the heel, and if it is not intelligently cultivated a prolonged drought that will ordinarily have no more effect on, let us say, *L. candidum*, *croceum*, *monadelphum*, *pomponium*, *pyrenaicum*, and even *pardalinum*, than perhaps a slight stunting of growth, will send *L. Parryi* straight to the gardens of Paradise. An abnormally wet autumn such as we have to bear with from time to time will also have the same untoward result.

The two main points, therefore, the would-be grower has to bear in mind when dealing with this Lily are adequate provision against excessive dryness on the one hand and excessive moisture on the other. This is more easily said than done, for while it is simple enough to guard against an excess of wet by providing quick drainage under the bulbs, the very fact that such drainage carries off all natural moisture rapidly renders it the more necessary to arrange some plan for watering the subsoil in case of need. The gardener may not have occasion once in a decade to use such watering arrangements as his ingenuity may devise, but the day of reckoning will inevitably come sooner or later, and woe betide the bulbs if, for instance, a scorching drought of the 1911 variety catches him unprepared. Here and there, as, for instance, in the late Sir Henry Yorke's wood garden at Iver, or the so-called American gardens of Mr. Leney at Saltwood, one may find perfect natural conditions in a loose top soil, brought down by the floods of countless ages, overlying a water-bearing stratum, but such ideal instances are all too few. Where they prevail no adventitious watering or drainage arrangements are necessary, and *L. Parryi* should be perennial: elsewhere some preparation must be made for it.

The soil conditions in which *L. Parryi* flourishes are those afforded by a deep, loose, gravelly or gritty loam, with a fair proportion of leaf-mould and crushed charcoal, in as sunny a spot as you please, and with some ground-shading shrub of gentle growth to serve the triple purpose of support for the stems, shelter for the young shoots against the cutting winds of March, and a screen to keep the earth cool in summer; if on the side of a slope so much the better, but if on the flat there must be no doubt about the drainage, even in such porous soil, and the bulbs should each be laid on a 5-inch inverted pot. It is better to err on the side of excessive drainage, for, as already indicated, the subterranean water supply with which the bed must of necessity be provided, if perchance Nature has not already seen to it in her own way, will enable the gardener to counteract any tendency to over-dryness.

The absence or presence of lime has undoubtedly a very important bearing on the cultivation of Lilies in general, and whatever may be the case where the wild plants are concerned, it seems almost certain that in this country the Western American Lilies with rhizomatous roots are better without it; *L. Parryi* certainly is. An absence of lime, however, especially in beds and borders of made ground, is often associated with an acid condition of the soil—fatal to all Lilies—and according to the chemists this may largely be neutralised by aeration; for that reason the top soil of the *L. Parryi* bed cannot be too open and crumbly. "A little peat" is not infrequently recommended for *L. Parryi* by horticultural scribes and the compilers of catalogues, but it is not necessary nor even desirable.

So far as the writer is aware nine-tenths of the bulbs of *L. Parryi* offered for sale in this country are imported from California, where they are collected in the wilds. It is for them a long journey and a dry one, which generally leaves its mark on the majority of the bulbs, and is at the bottom of many wearisome disappointments. The wise man will refuse to be hurried, and, realising that the planting of these soft and travel-stained bulbs must almost inevitably lead to failure, he will pot up the imported bulbs for the first season, keeping them in the convalescent home one finds in some corner of every garden, and when planting time comes round again putting out such as are sound and have developed strong roots. "Planting time" is, after all, a vague term, and in the case of *L. Parryi* implies a period of a week or two after the seeds have ripened. If there are no seeds let the bulbs be put into the ground about six weeks

after the passing of the flowers. They may be planted about 6 inches deep in a cylindrical hole about 4 inches in diameter—easily made with a length of iron stove pipe, fashioned and used like a huge cheese-taster—filled almost to ground level with fine lime-free sand. Before winter comes round care should be taken to see that the old, hollow dried stems are not used by a horde of slugs, millipedes, wire-

to it. As the years go by generation after generation of seedlings will be raised, and if the writer's limited experience is any criterion, each succeeding batch of seedlings will be just a trifle more robust than its forbears, and rather better able than they to battle with the vagaries of our climate without hoisting the white flag.

With a good supply of bulbs in the reserve bed one can afford to be comparatively reckless

effects of lime on their growth can only be properly observed in this matter.

Some day perhaps it may not be necessary to take any more trouble with *L. Parryi* than one does with the "common" Lilies of the garden, but for the present, unless one is blessed with a naturally perfect soil, it is not possible without special cultivation to give it an assured place in the category of perennial Lilies, nearly all

FIG. 96.—LILIAM PARRYI : SHOWING THE PURPLE MARKINGS THAT SOMETIMES OCCUR ON THE PALE YELLOW SEGMENTS.

worms, and other riff-raff of the soil, as a sort of tube railway lift down to the bulbs. Many a score of Lily bulbs is lost in this way.

Having once obtained a little seed from his potted bulbs the grower will soon find himself the happy possessor of a panful or two of seedlings, and in a couple of years or three he should have at hand a supply of home-raised bulbs, which will render him independent of the imported article with all the drawbacks attached

in planting bulbs of *L. Parryi* about the garden, as often as not in experimental fashion, for while the resulting wastage is usually heavy—always, indeed, much heavier than when the bulbs are planted in prepared beds, and the growth seldom so fine—one can make good most of the losses from one's stock of seedlings, with the comforting knowledge that the bulbs cost one nothing. It is by such trial plantings that one learns a good deal of the ways of diverse Lilies, and the

of them, curiously enough, limestone plants. The illustration (fig. 96) shows the purple markings often to be seen on the petals of *L. Parryi*, but these markings are not a constant characteristic in the case of home-raised seedlings, and as often as not are absent: on the other hand, one may frequently find flowers in which the markings are far more numerous than in the specimen from which the artist has drawn the figure. *A. Grove.*

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

ONCIDIUM.—There are numerous *Oncidium*s which may be grown successfully in a cool house under the same cultural conditions as *Odontoglossums*, and among them are some of the most useful and beautiful Orchids in cultivation. I refer in particular to those belonging to groups which embrace *O. macranthum* and *O. superbians*. The plants are now producing their flower-scapes, which grow many feet in length. Therefore it is desirable to train the spikes so as to display the flowers to the best advantage. It is a good plan to place neat, painted sticks around the edges of the pots at equal distances and to twine the spikes around the outsides of them. There is a considerable advantage in training them. It is best to do this before the spikes grow too long, and the ends of the spikes should remain loose for, say, 6 inches or a foot, as they are very brittle and soon snap. As the flower-buds are produced guard against attacks of thrips, greenfly, and other insect pests. Small punctures in the petals are the first indication of attacks by thrips, but plants that have been sprayed at regular intervals, as advised previously, will be but little troubled in this respect. When the flower-buds can be separately discerned the plants should be placed in a very light position in a cool house, for under these conditions the colour of the flowers will be enhanced. Spray the plants overhead whenever the outside conditions are favourable, and keep the atmosphere moist.

ONCIDIODA COOKSONIAE (COCLIODA NOEZLIANA × ONCIDIUM MACRANTHUM).—This hybrid Orchid produces spikes similar in character to *O. macranthum*, and bears purple-scarlet flowers. The plant will grow well if afforded a similar treatment to *Odontoglossum*, but it requires to be shaded carefully during the summer. Protect the flower-scapes from slugs by binding a small piece of cotton-wool around the stalk at the base, and place Potatoes, hollowed out, as traps for slugs and woodlice.

MILTONIA VEXILLARIA.—The plants of this useful species are producing their flower-scapes. Cultivators differ as to the best season for repotting these plants; the time should be governed by the conditions under which plants are cultivated. In the neighbourhood of large towns and manufacturing districts the plants frequently suffer considerable damage in winter owing to the deleterious atmosphere injuring the foliage. In such places it is not advisable to disturb the plants in the autumn by repotting them. Some of the finest specimens I have ever seen were repotted just as the flower-scapes appeared in the spring. It is at this season that the new roots are produced, and by repotting at this period the roots get hold of the fresh compost immediately, and no ill-effects are experienced. Use ample materials for drainage, and employ compost consisting of equal parts fibrous peat, broken leaves and Sphagnum-moss chopped moderately finely, with sufficient sand to render the compost porous. Carefully shade all repotted plants from strong light, and promote a moist atmosphere until the plants get re-established.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady Northcote,
Eastwell Park, Kent.

OUTDOOR VINES.—Vines are not grown so extensively out-of-doors for fruiting as formerly, but they are planted for ornamental purposes, and there are many corners on sunny walls in the warmer parts of the country where suitable varieties would repay for a little more attention than is usually afforded them. Too often the vines are tangled masses of untrained growths; the bunches are neither reduced in numbers nor are the berries thinned, and as the season advances the plant becomes covered with

mildew. Under such treatment it is useless to expect a crop of Grapes. Established vines, if not already attended to, should be pruned at once and the bark washed with a strong solution of Gishurst Compound or other insecticide to destroy red spider and other insect pests. When the rods are cleansed train them evenly over the wall, allowing sufficient room for the young shoots to develop. Where it is intended to plant young vines this season the border should be prepared now, so that the soil may become settled before planting. A south or south-west wall is practically the only position suitable for outdoor vines, which thrive in any good garden soil; if the ground is not suitable the top portion should be removed and good loam substituted. Make provision for efficient drainage and do not use rank animal manures, which, when employed in large quantities, often favours the development of mildew, which is the chief trouble with this crop. Wood-ash, lime rubble, charcoal and a little crushed bones should be mixed with the loam and the soil made firm. Do not plant the vines for another month at the earliest, when the soil will be warmer and the roots will develop quickly. Royal Muscadine, Sweetwater and the Strawberry Grape are the best varieties for planting. Chasselas Vihert produces slightly larger berries, which ripen earlier than those of Royal Muscadine. This variety should be given a trial where outdoor Grapes are grown.

GRAFTING FRUIT TREES.—In most gardens there are inferior sorts of Apples, Pears or

FIG. 97.—WHIP OR TONGUE GRAFTING.

FIG. 98.—CROWN OR RIND GRAFTING.

Plums, and healthy trees may be grafted with better varieties. In view of grafting them the trees should have been already headed down. The sap will soon be rising, and as soon as this is apparent the work should be taken in hand. Cut a little more off each branch so that the scions are inserted in fresh wood. There are several methods of grafting, all of which may be carried out with success under ordinary conditions.

CROWN OR RIND GRAFTING (see fig. 98).—With large or moderate-sized trees—as in the case of those headed down—crown grafting is the most convenient method. The scions having been cut off in the winter and inserted in the soil in a cool, shady border, should now be cut to about 6 or 8 inches, leaving three or four buds on the top part. The lower portion should be cut in a sloping direction and neatly fitted in an incision already made in the bark of the stock. Bind the union, but not too tightly, with matting and cover with grafting wax or clay.

WHIP OR TONGUE GRAFTING is suitable for very young stocks. Cut off the top of the

stock at a joint and slice off a portion about 3 inches long, as shown in fig. 97, with a reverse cut at the top to form the tongue. Cut the scion to fit the stock, making a notch to fit in the one in the stock. Although not shown in the illustration, a slight shoulder may be made to rest on the top of the stock. The scion should have three buds. When the stock and scion are unequal in size see that at least one side of each are in juxtaposition. As with crown grafting, tie with matting and cover the union completely with clay or wax to exclude the air. Watch the grafts closely in times of drying winds, and if cracks appear in the clay or wax damp the material and press it with the hand to make it smooth, filling up cracks with fresh clay or wax.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl Beauchamp, K.C.M.G.,
Madresfield Court, Worcestershire.

SUMMER CHRYSANTHEMUMS.—In addition to raising a stock of these plants from cuttings, divide the old stools to furnish early-flowering specimens in neat bush form. When these Chrysanthemums are well rooted, whether in pots or planted out in frames with a little fermenting material, for furnishing bottom-heat, afford plenty of ventilation, so that they may be hardy for planting out at the end of April. Good varieties for the purpose are *Mme. Desgranges*, *Queen of the Earlies*, *Precocity*, *Horace Martin*, *Harvest Home*, *Nina Blick*, *Goacher's Crimson*, and all of the *Massie* family. Do not fail to plant in the reserve garden a good stock of Chrysanthemums and other flowering plants that may be drawn upon at any time of the year, to make good losses in the decorative quarters.

THE PLEASURE GROUNDS.—No other part of the gardens is expected to afford greater enjoyment or variety than the pleasure grounds, and those in charge should utilise every possible means to maintain them in the highest possible condition with a variety of beautiful flowers and foliage plants. One of the greatest helps in obtaining new ideas is to take frequent notes throughout the seasons, drafting them into a scheme to be put into practice at the proper time. A garden may be laid out by the most skilful architect and in the most elaborate manner possible, but unless the gardener exercises constant skill and attention in maintaining a high standard it soon becomes uninteresting, and fails to please. There is no such thing as finish or finality in a garden, and it requires unceasing energy and forethought to develop it and make the most of its capabilities; therefore every opportunity should be embraced for adding to its attractions. Things always proceed most smoothly when there is a good understanding between master and man, and the gardener must not expect to be an autocrat of the "Corney Grain" type, for occasionally the non-technical man can offer suggestions which even the professional gardener can put to good use.

BORDER PHLOXES.—Varieties of *Phlox decussata* provide some of the best flowering plants for arranging amongst shrubs as well as in the herbaceous border proper. Young plants always give the finest trusses of bloom, and now is a suitable time to dig up the old stools with a view to selecting suitable portions from the outside for re-planting. Each new set should have three or four crowns. Where it is possible to do so, it is an advantage to plant in fresh beds, as the *Phlox* is a gross feeder, and after a time exhausts the soil. In any case the ground should be trenched deeply, incorporating plenty of animal manure at the bottom, and a little bone meal on the top. *Coquelicot*, *Lord Rayleigh*, and *Tapis blanc* are three excellent varieties.

SWEET PEAS.—Plants that were raised three or four in each 4-inch pot should be gradually hardened, preparatory to planting them out in well-prepared trenches in ground that was manured heavily last autumn. Although the Sweet Pea needs plenty of manure, fresh dung should never be used except for mulching.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

PINES.—Pay unremitting attention to such details as watering the plants, the temperatures of both house and bed, and the admission of air to fruiting plants. Reduce the supply of water to plants the fruit of which is on the point of colouring. Ripe fruit that may not be required for immediate use can be kept back for two or three weeks by removing the plants to a dry, airy house, such as a late vinery or Peach house, keeping them dry. Beds in which successional plants are grown, if composed of tan, or other fermenting materials, will occasionally require turning and partly renewing to maintain the bottom-heat at 70° or 80°. If necessary do this at once, and replunge the plants, carefully watching the state of the bed; should this become too warm, lift the plants as advised in the issue for March 14. Suckers or successional plants should be potted before the roots become too matted, and care should be taken to see that the soil in which they are now growing is thoroughly moistened before doing the work. Pot firmly, in ten or twelve-inch pots, according to the strength of the plants.

PEACHES AND NECTARINES.—Those crops that have commenced the stoning process—a very critical stage—require increased attention in their general management, and particularly so with regard to the correct regulation of the temperatures, which should not be subjected to fluctuations. At night the temperature may with safety be kept at about 63° or 65°, with a rise of about 10° by day until the stoning process is completed. Examine the inside borders carefully, as from frequent syringings and sprinklings the surface becomes an unsafe guide as to the true condition of the soil, inasmuch as it may be nearly dust dry, whilst the surface may be in a state of saturation. Continue to disbud by degrees all trees in successional houses, and ultimately leave no more young growths—except in doubtful cases—than will be required to furnish the trees for next year's crop. Tie in the young growths as soon as this can be done, and thin by degrees the young fruit, leaving rather more than may be required for an average crop till they have stoned. All misplaced or deformed fruits should be promptly removed. The flower-buds on trees in late houses are well advanced, and the anthers are showing in many cases. At this stage syringing should cease, and on dull or damp days a little artificial heat may be employed early in the day, but only sufficient to warm the pipes. This will bring about a circulation of warm, dry air, and so assist the fruits to set. Should there be the least trace of green fly on the trees fumigation must be resorted to before the flowers expand.

MELONS.—Preserve for as long a time as possible all the matured leaves on the plants. It is a mistaken idea to remove these, as is so often done when dealing with Cucumbers; therefore carefully guard against this loss of foliage, especially those leaves that are next to the fruit, or the latter will fail to finish satisfactorily, and will be deficient in flavour. The timely pinching of all young growths will aid in the preservation of all requisite foliage for the maturation of the fruit. Water the soil thoroughly with diluted liquid manure warmed to the same temperature as that of the house, also keep the evaporating troughs filled with water, as this will assist in keeping insect pests in check.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

MISCELLANEOUS PLANTS.—Fuchsias rooted last autumn are growing well, and the points of the shoots should be pinched to make shapely plants. Secure the central growth to a stake and sling up the side shoots thereto. Remove all flowers and re-pot as required. Hippeastrums are flowering freely, and the roots should be watered frequently with weak liquid manure. As the plants pass out of flower remove them to a heated pit and plunge the pots in a little

bottom heat. Promote a moist atmosphere to encourage growth. Introduce fresh batches of the plants into heat to maintain a succession of flowers. Make the main sowing of *Primula obconica*, and sow *Cinerarias* for autumn flowering.

EUPHORBIA JACQUINIAEFLOREA AND E. PULCHERRIMA.—Examine these plants at frequent intervals to ascertain if they are keeping in a plump condition. Remove all flower heads from *E. Jacquinaeflora* and spray the plants lightly overhead, as this favours the development of short-jointed growths which can be inserted as cuttings in April.

FLOWERING PLANTS.—*Cinerarias*, *Calceolarias*, *Primulas*, *Genistas*, and bulbs coming into flower require plenty of light and air. Very little fire heat will be necessary, for the blooms will last longer in a cool atmosphere. At the same time frost at night must be guarded against. Guano, liquid manure, or soot-water may be used occasionally as a stimulant. The spikes of *Mignonette*, *Pelargoniums*, and bulbous plants should be staked neatly, and successional batches of plants introduced into mild heat. Plants of *Fuchsia*, *Heliotropium* (*Heliotrope*) and *Lippia citriodora* (Sweet-scented *Verbenas*) should now be growing freely. Keep a diligent watch for insect pests and syringe the plants on bright days. Continue to propagate *Heliotropes* and *Verbenas*. Stop the shoots of *Pelargoniums* where growth is irregular, and train the shoots to allow ample room for their blooming. *Deutzias* that have finished flowering should be treated with care to favour the development of healthy wood, cutting back the old growths as soon as the flowers are over. Use the syringe freely to keep the plants clean; re-pot any specimens that require increased root-room before they make much new growth.

GESNERA.—The plants need a similar treatment to the *Gloxinia* as regards compost and management during the early stages. Place from three to six corms in each 6-inch pot an inch below the soil. Grow the plants in a house having a moist atmosphere, and an atmospheric temperature of 65°. Water the roots very sparingly at the start. When growth is active a little weak manure-water may be afforded twice weekly. Fumigate the house at intervals, as the leaves are subject to infestations of red spider and mite. Pot successional batches to prolong the flowering.

THE "FRENCH" GARDEN.

By PAUL AQUINAS.

HOT-BEDS.—As this is the best time for the marketing of Lettuces provision should be made where there is no hot-bed for cloches, so as to have a constant supply until those grown on the cold-beds are ready for cutting about April 20. A good method is to set the Lettuces at the bottom row of each frame, where there is more moisture, whilst the shade from the board will keep aphids in check. When the bulk of Lettuces has been removed clean the Carrots and weed the rows. Afterwards spread fine, black soil to cover the collar of the roots, which will retain the bright red colour and enhance the market value of the crop. Afford ventilation, but gradually, on every possible occasion when the conditions are favourable. The Turnips are well through the soil, and only one plant should be left where every three or four seeds were sown in one spot. The manure fly often attacks the cotyledons and young leaves, but very fine ashes or road sweepings scattered on the leaves when they are wet will stop the damage. On mild, calm days leave one light open at the top, and the next at the bottom to promote a current of fresh air in the frames.

OPEN-AIR CROPS.—Plants of the batch of Cauliflowers sown last October are in a prime condition for setting out. They are planted between the Cabbage Lettuces, allowing a distance of 2 feet between the rows and 18 inches between the plants in the rows. Cos Lettuces reared under the cloches through the winter are also ready for planting out; the variety *Paris Grey* requires a space of 18 inches by 12 inches in the row, but where *Paris White* is

grown, especially in heavily manured ground, 18 inches each way should be allowed.

HOT-BEDS FOR THE CROPS UNDER CLOCHES

—Cos and Cabbage Lettuces must be kept thoroughly cleansed, and as the plants are advanced in growth great care must be taken to shade them during times of bright sunshine. Whitewash should not be used for another fortnight at least, but place mats in position between 11 a.m. and 2 p.m. The Cabbage Lettuces grown in these beds should be marketed as soon as they are ready, to prevent the Cos Lettuces from becoming drawn.

UNHEATED FRAMES.—The crop of Radishes should be marketed whenever the roots are ready and before they check the growth of the Lettuces. An occasional watering on bright days will greatly help their growth. Ventilation is now afforded more freely, and in the case of the variety "Passion" a little air may be allowed at night in suitable weather to harden the plants in view of their removal from the frames and lights in two or three weeks' time.

MELONS.—Early Melons should be potted into 60-sized pots, and plunged immediately after in a manure bed, unless they are to be grown in a greenhouse. Better results will be obtained after the middle of April if all seedlings and plants are grown, till they are put in their final quarters, on a hot-bed, where growth will be harder and healthier than in a greenhouse. As soon as the plants have developed three leaves stop them by cutting the stem across the base of the third leaf; remove the cotyledons close to the stem, and take out the small eyes at their base. The plants should be on the dry side when the work is done, which should take place early on a bright day to facilitate the cauterising of the cuts. Afford ventilation daily to crops in the nursery beds for at least half an hour to change the atmosphere. Seeds should be inserted in sufficient quantity to ensure having a number of good plants to choose from at planting time. Seeds of Cucumbers may be sown in the same manner as recommended for Melons. Only short and hardy varieties should be chosen for growing in frames.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynningham, East Lothian.

LEEKs AND CELERY.—If the ground on which the remaining portions of these crops are growing is wanted the plants may be lifted, the leeks to be laid-in at the base of a north wall and the Celery placed upright, closely together, and covered, in a cool, dry shed or outhouse.

PEAS.—It is time to make another sowing, choosing a second early sort. The furrow should be made slightly deeper than for the last batch. Tall growing varieties are the more profitable, but where suitable sticks are difficult to obtain, those of medium growth must be relied on. Peas sown in January are sufficiently advanced to have soil drawn up on each side of the row, and the sticks placed in position for supports. Even quite dwarf sorts crop all the better when staked. If the plants have been forwarded in boxes, planting should be no longer delayed. The soil having been allowed to become dry, shake the roots free, and line in the plants at about 4 inches apart, if the ground be dry, leaving a shallow depression to be filled with water and afterwards filled up. Protect with short spruce branches, and let the subsequent treatment be such as will promote a strong, vigorous growth.

TURNIPS.—Successional sowings of this crop may now be inserted, with a view to having an uninterrupted supply of medium-sized roots. *Snowball* is a reliable, well flavoured variety for summer use.

SEED-SOWING.—Other seeds to be sown include Cauliflowers, *Magnum Bonum*, *King*, and *Erfurt*, which will turn in late in summer. Also more Brussels Sprouts, *Winningsstadt* Cabbage, and Savoy.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — Our Correspondents would oblige by delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPOINTMENTS FOR APRIL.

WEDNESDAY, APRIL 1—
Liverpool Hort. Assoc. Spring Sb. (2 days). B.G.A. Ex. Council meet.

THURSDAY, APRIL 2—
Linnean Soc. meet.

FRIDAY, APRIL 3—
Dundee Hort. Assoc. meet.

SATURDAY, APRIL 4—
Soc. Française d'Horticulture de Londres meet.

TUESDAY, APRIL 7—
Roy. Hort. Soc. Coms. meet. (Lecture at 3 p.m. on "The Cultivation of Amaryllis.") Hort. Club dinner and meeting: lecture by Mr. P. Amaury Talbot on "The Flora of Nigeria."

MONDAY, APRIL 13—
United Hort. Ben and Prov. Soc. Ann. meet. Bank Holiday.

TUESDAY, APRIL 14—
Kingsbridge Daffodil Spring Fl. Sh.

WEDNESDAY, APRIL 15—
Roy. Hort. Soc. Coms. meet (Special Daffodil Show, 2 days.)

THURSDAY, APRIL 16—
Manchester and N. of Eng. Orchid Soc. meet. B.G.A. (Watford branch) meet.

FRIDAY, APRIL 17—
Huntingdon Daffodil and Spring Fl. Sh.

TUESDAY, APRIL 21—
Roy. Hort. Soc. Coms. meet (Nat. Auricula and Primula Soc. combined Show.) (Lecture at 3 p.m. on "The Probable Origin of Existing Flowering Plants.") Lincolnshire Daffodil Soc. Show.

WEDNESDAY, APRIL 22—
Herefordshire Spring Fl. Sh., Shire Hall, Hereford.

THURSDAY, APRIL 23—
Nat. Rose Soc. Spring Ex. at R.I.S. Hall, Westminster, Midland Daff. Soc. Sh. at Birmingham (2 days). Roy. Botanic Soc. meet.

WEDNESDAY, APRIL 29—
Nat. Auricula and Primula Soc. (Mid. sect.) Ex. at Birmingham Bot. Gdns. (2 days). Perpetual Fl. Carnation Soc. Spring Sh. at Bournemouth (2 days). Roy. Caledonian Hort. Soc. Spring Show (2 days).

THURSDAY, APRIL 30—
Manchester and N. of Eng. Orchid Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 45.2°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, March 25 (6 p.m.); Max. 50°; Min. 35°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, March 26 (10 a.m.); Bar, 28.7°. Temp. 49°. Weather—Dull.

PROVINCES, Wednesday, March 25. Max. 45°, Yarmouth; Min. 42°, Aberdeen.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Rose Trees, Shrubs, Perennials, Lilies, etc., at Stevens' Rooms, King Street, Covent Garden, at 12.30 p.m.

MONDAY AND FRIDAY—
Herbaceous Plants and Hardy Bulbs, at 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.

TUESDAY—
Hollies and other Nursery stock, at Messrs. Paul's Nurseries, High Beech, Epping Forest, by Protheroe and Morris, at 12.

WEDNESDAY—
Perennials and Bulbs at 12, Trade Sale of miscellaneous Bulbs at 12, Japanese Liliiums at 2.45, Palms and Plants at 5, by Protheroe and Morris.

THURSDAY—
Roses, by Protheroe and Morris, at 1.

THURSDAY AND FRIDAY—
The entire collection of Orchids formed by Francis Wellesley, Esq., by Protheroe and Morris, at 1.

THURSDAY AND FRIDAY—
Alpine, Rock and Herbaceous Plants, at the Nurseries, Baldock Road, Letchworth, by Protheroe and Morris, at 12.

Every advance in soil science demonstrates the complexity of the problems which confront

those who seek to unravel the tangle of relations which subsist between the plant and the earth in which it lives. Yet every advance is a hopeful promise that this tangle shall be unravelled, and that before long the grower shall be able to control and modify soil conditions with even greater certainty than he can at present. It was but recently that the biological aspect of the soil came into prominence, and investigators are busy at the work of discovering the ways and habits of the micro flora and fauna of the underground. To-day it is the turn of the physical chemist—he who works on the border-line which lies between physics and chemistry. His recent discoveries have shown that in more subtle ways than was supposed the soil is the seat of changing and far-reaching chemical operations. The nature of these discoveries is described well in a recent article in the *Agricultural News* (XIII., No. 308), which deals with the phenomenon of adsorption and with the work of American investigators on the part played by adsorption in the physico-chemical processes which recur in the soil. The phenomenon of adsorption may be illustrated by pouring a solution of a dye into a tube packed with finely-ground chalk. If the tube be long enough it is found that the dye is separated from the solvent and is held by the chalk, so that the clear solvent issues at the lower end of the tube. With this in mind it may be imagined readily that if a solution of a mineral substance—for example, kainit or sulphate of ammonia—be poured on the soil, some, or all, of the dissolved salt might be adsorbed by the soil particles, so that if any of the liquid drained away that liquid would contain little or none of the mineral in question. This is evidently a matter of first importance in relation to the economic employment of soluble artificial fertilisers. Recent discovery carries us far beyond this point, for it has established the fact that the fine particles of such substances as charcoal may not only adsorb substances, but may exercise selective adsorption. For example, as is pointed out in the article referred to, certain substances can adsorb the constituents of a chemical compound at different rates. Thus if a solution of such a salt as potassium chloride be added to charcoal it is found that potassium in the form of potassium hydroxide accumulates in the solution, and that chlorine, combined with hydrogen to produce hydrochloric acid, is adsorbed. Mr. E. G. Parker (*Journal of Agricultural Research*, Vol. I., No. 3) has shown that soils also possess this power of selective adsorption, but that in accordance with the contrariety of things they manifest it in exactly the opposite way to that in which charcoal exhibits adsorption. For instance, if potassium chloride be added to soil potash is adsorbed more rapidly than hydrochloric acid. Wherefore it follows that the potash is as it were glued on to the soil particles, and the

hydrochloric acid is free to react with other mineral bases—lime, magnesia, and the like—and with them it forms salts. Thus it follows that not only is the potash held, but other substances, which may also serve as plant foods, are brought into the soil solution.

As by dropping a pebble into water ever-widening waves of change are produced, so by dropping water containing salts among the microscopic pebbles of the soil wide waves of chemical change are set up.

That these facts are of prime importance to a discovery of the true philosophy of manuring is self-evident. One example of this importance must suffice. If more than one substance be dissolved in water the mere presence of one of the substances in solution may affect the rate at which the other is adsorbed. For example, it appears that if kainit (crude potassium chloride) be mixed with nitrate of soda and dissolved in water the adsorption of potash is reduced, and hence less of the kainit remains in the soil than would have been the case had it been added alone.

As our contemporary points out, it is premature to apply this new-born knowledge to the practical problems of the efficient use of artificials; nevertheless, it is clear that the further study of adsorption by soils is bound to lead to results of great importance to the practice of horticulture and agriculture.

SMALL HOLDINGS.—In the House of Commons on Tuesday last Mr. Runciman stated that 6,271 approved applicants were still waiting for small holdings. Applicants under the Small Holdings Act had been provided with 182,020 acres, of which 157,104 were in England and 24,916 in Wales.

LA SOCIÉTÉ POMOLOGIQUE DE FRANCE.—The annual Congress of this society will this year be held in Grenoble; the date proposed is September 7. Among the questions to be dealt with are the raiser's rights in new fruits, how to teach fruit culture, the culture of Apples and Pears in pots, and terms to be used in the description of fruit and plant novelties.

ROSE CONGRESS AT BIARRITZ.—The Société Française des Roséristes will hold its annual Congress at Biarritz on May 29 to June 1 next, under the auspices of the Société d'Acclimatation du Golfe de Gascogne. A programme of the five days' festivities has been prepared. Apart from the Congress meetings, there will be visits to San Sebastian, Hendaye, Fontarabia, Cambo, and other places.

WORSHIPFUL COMPANY OF GARDENERS.—Arrangements are being made for a visit of delegates of the Worshipful Company of Gardeners to France, extending from June 7 to June 13, in order to study horticulture and to visit Versailles, Bourg-la-Reine, Roseraie de l'Hay, Verrières-le-Buisson, Olivet, Blois, Romarantin and la Ferté-Imbault. It is expected that the headquarters will be successively at Paris, Orleans, and Angers. The visit will be a state one, and the members will take with them the Company's corporate insignia, and will be everywhere officially received. Special pains have been taken to secure important introductions through the Foreign Office, and the French Government is giving all possible facilities. An interesting programme is in course of preparation by the French Ministry of Agriculture.

JAPANESE GARDEN IN THE ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION

(SEE "THE HORTICULTURAL RECORD," REVIEWED IN THE PRESENT ISSUE.)

BILLS OF VEGETABLE MORTALITY.—From statements in the French Press it appears that M. P. NOEL, Diector of the Laboratory of Agricultural Entomology (Seine-Inférieure), has endeavoured to express in terms of money the loss due to parasitic diseases of cultivated plants. M. NOEL computes that there are in France 350 different kinds of useful cultivated plants, of which 16 are fruit trees, 28 are vegetables, 33 forage plants and cereals, 14 forest trees, 34 ornamental trees and shrubs, 117 ornamental plants, and 85 medicinal plants. These 350 kinds of plants suffer from the attacks of 12,000 different kinds of insects—allowing that one and the same insect attacks more than one plant the number of insect pests may be reckoned at 6,000. The plants have to bear also the brunt of the attack of upwards of 4,000 fungi and other vegetable parasites. For the reason just given, that one and the same parasite attacks more than one kind of plant, M. NOEL assumes, for the purpose of his estimate, that the number of parasites which infest the 350 useful species or varieties of cultivated plants may be put at 2,000. Careful and extended analyses of the statistics of the Ministry of Agriculture and of Forestry, enquiries addressed to horticulturists and others, lead M. NOEL to estimate that the annual revenue derived annually from the cultivation of these plants is about 9 milliards of francs (£36,000,000 sterling). From other and extended enquiries he concludes that the depredations of the 8,000 insect pests and plant parasites cost the country each year no less than 3 milliards of francs (£12,000,000 sterling). In other words, the sum exacted from the cultivators by these pests amounts in two years to more than the price of the indemnity (5 milliards) paid by France to Germany at the conclusion of the war of 1870. Truly and in grim ironic sense, "peace hath her victories no less renowned than war."

"THE BOTANICAL MAGAZINE."—The issue for March contains illustrations and descriptions of the following plants:—

ARISTOLOCHIA GIGANTEA, tab. 8,542.—*Aristolochia gigantea* must not be confused with *A. gigas*, which is synonymous with *A. grandiflora*. *A. gigantea* formed the subject of the Supplementary Illustration in the *Gardeners' Chronicle*, September 17, 1892. The flowers are more than 6 inches wide and the colour brownish-purple with pale-yellow reticulations. Contrary to most *Aristolochia* flowers the blooms of *A. gigantea* are fragrant.

RIBES LAURIFOLIUM, tab. 8,543.—We are indebted to Mr. E. H. WILSON for the introduction of this charming little shrub, which he found growing wild in Western Szechuan at an altitude of 5,000 feet. The blossoms appear in February and the sexes are on distinct plants; from these circumstances it is expected that fruits will develop only in exceptionally mild seasons. The garden value of *Ribes laurifolium* is more as an early blooming subject for the rockery and other places suitable for dwarf plants. Specimens planted on the rockery at Aldenham House, Hertfordshire, have been very beautiful this season.

SALVIA ULIGINOSA, tab. 8,544.—This beautiful, blue-flowered Sage has every appearance of making a good garden plant, especially as it flowers from September to November, and has so far proved to be hardy in this country. It is a tall grower; the loose, erect shoots attain to a height of 6 feet—just the kind of plant that is serviceable for the back of the hardy flower border. The flowers are a beautiful shade of opal blue.

KNIPHOPIA CARINATA, tab. 8,545.—Plants of this yellow-flowered *Kniphofia* raised at Kew in 1892 only blossomed in September, 1912, but they flowered again in the following year. This points to the species being a shy bloomer, although it may be that, like most seedlings, a long time is necessary before the adult stage is reached. The species is new to science, and should offer excellent material for the hybridist. The raceme is

about 6 inches long and densely packed with clear, yellow flowers.

COTONEASTER TURBINATA, tab. 8,546.—This species was received from China, the home of so many other *Cotoneasters*, by Mr. de VILMORIN, and the original flower fruited in that gentleman's garden in 1903. Specimens presented to Kew have reached a height of 6 feet, and everything points to the plant being hardy and vigorous. The flowers appear in July, which is later than in any other *Cotoneaster*, and this is an advantage, for then most flowering trees and shrubs are getting over. The inflorescence is a pyramidal corymb of white flowers, which are sometimes tinged with purple and sometimes with rose.

PLANTS IN FLOWER AT MADRESFIELD COURT.—The following shrubs are in bloom in the gardens of Lord Beauchamp, at Malvern, Worcestershire:—*Corylopsis spicata*; *Ceanothus dentatus*, with beautiful dark-blue flowers and trained on a south wall; *Forsythia viridissima*, *F. intermedia*, *Magnolia stellata*, *Berberis Darwinii* and *Ribes sanguineum*. Bulbs blooming in grass include:—*Muscari Heavenly Blue*, *Grape Hyacinths* (a lovely mass of blue), *Chionodoxas*, *Scillas*, *Hyacinths* and *Daffodils*. In the wild garden are *Violets*, *Primroses*, *Pulmonaria* (*Lungwort*), *Lent Lilies* and *Helleborus orientalis*; whilst on the rockery are *Saxifraga Burseriana major*, *S. Boydii* and others, *Primula cashmeriana*, *Polyanthus*, and *Gentiana acaulis*.

PRIMULA OBCONICA AND SKIN IRRITATION.—The well-known skin irritation caused by handling *Primula obconica*, Hance, has been investigated recently by Professor Dr. E. ROST (*Arch. aus. den Kaiserlichen Gesundheitsamte*, xlvii., Heft i, 1914). This observer gives a careful account of the effects produced by the plant, confirms previous investigators in ascribing the poisonous effects to the glandular secretion of the hairs covering the plant, and shows that none of the forms of *P. obconica* in commerce is innocuous. This is certainly true of the ordinary *obconica* form, but, as pointed out by Professor BAYLEY BALFOUR in his paper read at the *Primula Conference* last year, it is not true of *P. sino-listeri* Balf. fil., which is one of the many microforms of the species *P. obconica*. Dr. ROST shows that the symptoms set up by *P. obconica* are due not to mechanical irritation but to the action of a poison—of unknown nature—on the skin. As a result of this action eczema and dermatitis are produced. The period of incubation—that is the time before the effects are produced—ranges from a few hours to so much as sixteen days. Dr. ROST is of opinion that complete immunity from the poison does not exist. Nevertheless, it is certain that many who work with this plant suffer no ill-effects from handling it. The symptoms are confined closely to the place of contact, and the eczematous region tends to form a concentric area. The itching which results from infection is disagreeably continuous, but is apt to be more pronounced during the morning and evening. Those who are particularly susceptible to the poison should avoid working among the plants with bare arms, since the more delicate the skin on which the poison exudes the more certain are the irritant effects. Care should be taken to protect the infected part from pressure, and Dr. ROST states that zinc powder applied locally alleviates the irritation. It will be evident from the foregoing that those who are markedly susceptible to the poison may secure complete immunity if they wear gloves whilst working among the plants, rinse the gloves afterwards in methylated spirits (in which the poison is soluble), and keep their arms covered.

MUNIFICENT PUBLIC GIFTS.—In addition to his gift of a public park to Hucknall, referred to on p. 205, the Duke of PORTLAND has presented to the town of Mansfield a six-acre

pleasure-ground, at present leased by the town council from the Duke. To Kirkby-in-Ashfield he has offered to present three recreation grounds, and to Mansfield Woodhouse over 13 acres known as Yeoman's Hill, to be kept as an open space for the benefit of the parish. The Duke has also sent cheques to assist the local authorities to fence off the land.

LONDON GARDENS.—Mrs. O'SULLIVAN is engaged in developing a movement known as "London Gardens," and the scheme is affiliated to the Royal Horticultural Society. The object is to encourage the cultivation of small gardens in London, as well as window and roof gardening. The promoters will deal with London only, and will make fortnightly exhibits at the Royal Horticultural Society's Hall, Westminster, in conjunction with the society's fortnightly meetings, when special prizes will be awarded.

WOMEN GARDENERS.—At the annual meeting of the Governors of the Horticultural College, Swanley, Kent, the President, Sir JOHN COCKBURN, in moving the adoption of the report, said the Horticultural College at Swanley was one of the pioneers of the higher education of women. Women there went through a practical training in gardening, and were fitted to take important posts which many old students held, both in this country and the Overseas Dominions. A Swanley student, Miss GERTRUDE WATKIN, had received the appointment from the Home Office of gardening instructor at the Borstal Institute for Girls at Aylesbury.

PARIS INTERNATIONAL HORTICULTURAL SHOW, 1915.—The committee appointed to carry out the details for the show next year has just been constituted by the society, and is divided into four sections. One will undertake the organisation of the Congress, receptions and outings; another will deal with the schedule of prizes, classes, etc.; a third will look after the advertising; and a fourth will deal with the question of subsidies, special prizes and patronage.

NURSERY NOTES.

PRIMULAS AT FOREST HILL.

It has been our pleasure on many occasions to visit Messrs. Jas. Carter and Co.'s Forest Hill Nursery at Primula time, and, although our visit this season was made rather late, the plants were the finest we have seen for a long time. Everyone is aware that the nursery culture of flowering plants differs in many respects from that practised by gardeners. The advantage is on the side of the gardener. The nurseryman has a different object in view, his concern being chiefly to raise seeds, which imposes the greatest strain on the energies of the plants. When, therefore, the plants are of the highest quality after setting a quantity of seeds, as is the case at Forest Hill, the utmost praise is due to the growers. Well-grown plants show the varieties at their true worth, and at Forest Hill house after house is filled with some of the most beautiful *Primulas* in cultivation. The cream of the collection is the beautiful variety named *Princess May*, which bears on stout stalks trusses of large, blush-rose coloured flowers, set off by the pale green, palm-shaped foliage. The greater part of one of the glass-houses is filled with plants of this variety. Some are growing in small (sixty-sized) pots; this method should commend itself to those who are required to furnish plants for table decoration, as the *Primulas* flower splendidly under these conditions, and make fine little decorative specimens. The flowers do not suffer in size, and the spike is in suitable proportion. *Hulborn Coral* is a giant form of the *sinensis* type, taking its name from its coral-red colour. The flowers are large, the petals of good substance, and of a rich shade. In the same house

with the two last-named varieties is the new Stellata variety, Fairy Queen, which has ivory-white petals, with a zone of carmine and a gold centre. There is promise of an abundant seed crop of this variety, for the plant not only blooms freely, but also sets the seed-pods well. It is in every way a satisfactory plant for growing. Plants of this variety are also grown in small pots, the blooms being particularly large. White Stellata and Pink Stellata are two good types of the Star Primulas, and both are useful for supplying cut blooms. The varieties Vermilion, Pink, Salmon, Crimson, and Ruby are all good in their respective colours. Carmine Empress is one of the deepest-coloured varieties among the double-flowered kinds, and produces a very bushy truss. Mauve Pink is exceptionally free in blooming, sending up secondary trusses from the base. Holborn Crested is a distinct variety of great beauty. The large mauve-pink flowers bear a broad band of yellow around the eye; the crested takes the form of

stellata novelties in white, pink, salmon, blue, crimson, lilac, and other colours, all of which are valuable for conservatory and greenhouse decoration. They have also some remarkably fine forms of *Primula obconica*; their variety Royal Purple impressed us as being one of the finest colour developments in this flower we have seen. The strain is known as Excelsior, and varieties of reddish-magenta, pale blue, lavender-blue, Hydrangea-blue, purple, white, crimson and other shades are all good.

Cinerarias and Gloxinias are also extremely well grown. There is about the whole of this well-managed nursery an air of alertness which always impresses visitors favourably.

SCOTLAND.

RESIGNATION OF MR. P. HARPER.—Much regret is felt in Aberdeen and elsewhere that Mr.

FIG. 99.—ROCKERY EXHIBITED BY MESSRS. PIPERS AT THE R.H.S. HALL ON TUESDAY LAST. (See p. 225.)

fimbriated edges round the petals, the foliage being also crested. Elaine is a well-known white variety, and is to be found with both Fern-leaf and palm-leaf types of foliage. It is a favourite with growers, being one of the most freely-flowering of all Primulas. Snowflake is a semi-double variety; the petals are sometimes faintly suffused with rose-colour. Alba magnifica, which belongs to the *sinensis* type, is pure white, and so is the interesting variety known as Bouquet White, which has a whorl of leaf-like bracts surrounding the large pips.

Among novelties of promise, Rose-Magenta may be mentioned; the petals are of a very beautiful shade, harmonising well with both lighter and darker tones. Double Scarlet has brilliant flowers of the *sinensis* type, and is one of the finest varieties of this shade. Other good varieties are Princess of Wales, white, delicately tinted with salmon; Giant Salmon, Vivid (double carmine variety), and Crimson King. Messrs. Carter's possess a fine strain of

Peter Harper, keeper of the Duthie Park, Aberdeen, has been compelled through ill-health to tender his resignation.

DUMFRIES CORPORATION CUP.—The Dumfries Town Council has offered the large silver cup, which was at one time competed for at the show of the now defunct Dumfries and Galloway Horticultural Society, to the Dumfries and District Horticultural Society, which was founded last year.

AGRICULTURAL RESEARCH WORK BY CARNEGIE SCHOLARS.—The Carnegie Trustees have issued a report on the work of their bursars for research work since the establishment of the scholarships in 1908.

PLEASURE GROUND FOR ABERFELDY.—The Marquis of Breadalbane has offered the town of Aberfeldy the Den and Falls of Moness at a nominal rental of 1s. per annum, on several conditions easy of fulfilment, and the Town Council has accepted the gift. Miss Jessie Campbell, Aberfeldy, has offered £200 to repair the walks and bridges and to restore the mineral well.

EDINBURGH'S BOWLING GREENS.—Owing to local opposition, the provision of bowling greens at Piershill will not be proceeded with, but the Council is recommended to approach the Board of Works for ground for two greens at the Meadowbank entrance of Holyrood Park. Another bowling green is to be provided at Morningside.

SEED-TESTING STATION.—A seed-testing station has been established by the Scottish Board of Agriculture at 21, Duke Street, Edinburgh. The station is to be under the charge of Mr. T. Anderson, formerly of the botanical department of the Edinburgh and East of Scotland College of Agriculture, and also of the Armstrong College, Newcastle-on-Tyne. The station comprises a laboratory, two testing rooms and an office, and the system is to be the same as that followed in the Irish seed-testing station.

THE PROPOSED NATIONAL PARK AT LOCH LOMOND.—The proposal to establish a national park on the shores of Loch Lomond, at Balloch, Dumbartonshire, is assuming a practical shape. Sir John Stirling-Maxwell, of Pollok, and Mr. A. Wyllie, of Cordale, have secured an option for the purpose of the purchase of the Balloch Castle estate, and have deposited the sum of £500 each. The purchase price is £30,000 and the Town Council of Glasgow is asked to provide £10,000 towards the amount required, the intention being to raise the remainder by subscription.

ALLOTMENTS IN EDINBURGH.—The allotments already provided in different parts of Edinburgh have been so much taken advantage of that a further scheme for the St. Leonard's district is in contemplation to supply disappointed applicants for the last allocation of allotments in the district. It is proposed to form twenty-six additional allotments.

PROPOSED PUBLIC PARK FOR FALKIRK.—The estate of Bantaskin, Falkirk, is for sale, and there is a proposal that it should be purchased for the purposes of a golf course and recreation ground for the town of Falkirk. The Corporation having declined to furnish the necessary funds a movement is on foot to raise the money by public subscription.

THE "THOMSON" CHALLENGE CUP FOR GRAPES.—Mr. James Dixon, Rowallan, having won outright the "Massie" Challenge Trophy offered for Grapes at the autumn shows of the Royal Caledonian Horticultural Society, Messrs. William Thomson and Sons, of the Clovenfords Vineyards, have offered a Cup of the same value to be competed for in the class for six bunches and on the same conditions as before. The trophy is of the value of fifty guineas.

EDINBURGH PARKS AT THE LYONS EXHIBITION.—Among the numerous exhibits which are being sent by the Corporation of Edinburgh to the Exposition Internationale Urbaine de Lyon are views in colour of the parks and gardens of the city. *Corres.*

FOREIGN CORRESPONDENCE.

PRIMULA OBCONICA.

On attentively examining the reports which from time to time have found their way into the papers as to the poisonous nature of *Primula obconica*, two things appear to go like a red line through all these communications: (1) The suspicion of those who have suffered from those ill effects that some strains are more virulent than others, and (2) that the evil effects only appear in the more advanced stage of cultivation. May I now be allowed to make a few statements in support of these two points? Mrs. Heinrich received two pots of *Primula obconica* when this plant was yet comparatively rare. They were then in flower and of the original pale lilac tint. A few days afterwards an ominous irritation on fingers and wrists set in, and, having read before notices in the gardening papers, I at once said: "*Primula*

obconica! away with it." They went and all was well again. However, as the improved strains made their appearance, Mrs. Heinrich could not resist the temptation and last year ordered seed to try "whether it had not only been imagination after all, obconica is of such exceeding beauty that we cannot do without it." Very well! The seedlings thrived amazingly and no ill-effects were noticed. They commenced flowering beautifully, nothing happened. They were cut for vases and handled without any precaution having been taken, and we were already rejoicing that the stately plant need not be sent into exile again. But, lo! Fate strode along its evil path again. As the inflorescences began to lessen unsightly shrivelled blossoms spoiled the handsome trusses; to remove those Mrs. Heinrich reached across the stage in short sleeves. Next morning the mischief was done; the under-side of the wrists showed the well-known irritation. "Then it can only be the pollen to cause it and not the leaves, for I have now been handling the plants for over six months without any ill-effects," and to prove it she bravely rubbed the upper side of her wrists with the decayed blossoms, and, sure enough, the same night the irritation followed. As all plants with the original lilac tint had been sorted out into the front row, so that Mrs. Heinrich had mostly to reach across those, she has a feeling as if plants reverting to the original mauve or lilac tint were more virulent, for what she had used for cuttings were mostly of the rosy tints improved. The two presentation plants spoken of were also of the original tints; they were also in the advanced state of cultivation and commenced their action at once, while the seedlings, tended for six months without evil effect, did not prove virulent until they reached about the same condition as the presented plants.

All this may, of course, be supposition, but in so important a case I thought it well worth recording in order to direct observation into that channel. The case of hay-fever which is said to be caused by the pollen of, I believe, Corn (Rye), and which also only attacks predisposed persons, might offer an analogy as to the ill-effects such plant-pollen may produce on mankind. The microscope has not disclosed any appearances of a suspicious nature in the pollen grains of *Primula obconica*. E. Heinrich, Planegg (Bavaria).

[There appears to be no doubt but that the irritation is caused by a poison excreted by the glandular hairs of the petioles, flower peduncles, etc. See note on p. 221.—EDS.]

CORONA DI NOVIA.

In the *Gardeners' Chronicle* of January 24 last, p. 64, C. B. asks if any reader can give him the name of a shrub growing freely here and known as Corona di Nova. I think that I can answer this question. Although the plant grows freely here it does not belong to this country, but to Europe, and it is the very well known Spiraea. There are many kinds, and nearly all do very well in this climate. Horacio M. Peluffo, Buenos Aires.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE HISTORY OF AQUILEGIA STUARTII.—In his notes upon "Aquilegias and Their Hybrids" (see p. 207), the Rev. David R. Williamson states that the introducers of *A. Stuartii*, Messrs. Cocker, of Aberdeen, informed him that it was the result of a cross between *A. coerules* and *A. glandulosa*. This is not correct. At the International Hybrid Conference held under the auspices of the Royal Horticultural Society in London in 1899, the late Dr. Charles Stuart contributed a paper upon "A Few Notes on Reproduction in Hardy Plants," and in the course of his remarks he dealt very fully with *A. Stuartii* and how he raised this exquisite hybrid Columbine. He stated that in May,

1880, having plants of *A. glandulosa* and also *A. Witmannii* in flower in pots at the same time, he fertilised a flower of the latter species with pollen from *A. glandulosa*. A ripe pod of seed was gathered in less than a month and sown at once. Seven plants lived, and were planted out on a sheltered border in the autumn. Their existence was forgotten, till, at the end of May of the following year, a friend who was staying with Dr. Stuart came upon the first open flower on one of the plants. The visitor asked where the plant had come from, as the flower was the finest he had seen of the Columbine family. Dr. Stuart could hardly tell until he referred to his notebook, but he was quite aware they were crossed seedlings. The seven plants all bore flowers identically the same, the top blooms measuring more than 4 inches across. The following season, that was in 1882, Dr. Stuart took flowers to a meeting of the Berwickshire Naturalists' Club, and they were submitted to the late Professor Balfour, of Edinburgh University, and the late Mr. John Sadler, then Curator of the Edinburgh Botanic Gardens; both gentlemen, in conjunction with many other competent judges, considered *A. Stuartii* a first-rate novelty, and it was there and then named by Professor Balfour. Dr. Stuart stated that he had grown *A. glandulosa* on and off for forty years; he found it a notoriously shy flowerer, and he used many years ago to consider it a triumph to get it to display its beauty at all. He claimed for *A. Stuartii* that it was an improved form of *A. glandulosa*, refined in colour, free blooming, very large and attractive in appearance, and it is perfectly hardy and flowers three weeks before other Columbines, always coming true from seed. I find it difficult to accept the Rev. David R. Williamson's statement about the difficulty of the cultivation of this hybrid Columbine, which he attributes to Dr. Stuart. I remember a pleasant week-end visit to Dr. Stuart's garden at Chirnside, in the fertile mense of Berwickshire, and I shall always picture in memory a three-year-old bed of *A. Stuartii*, with its thousands of beautiful blue-and-white blossoms. That bed was indeed a sight, the plants a perfect sea of flowers and clothed with fine, strong foliage. Dr. Stuart's method of culture was to dig a piece of ground 2 feet deep, adding an abundance of well-decayed manure to the subsoil. The bed was then raked smooth, newly ripened seed being sown thinly in rows, the plants allowed to remain where they were to flower. The seedlings were thinned out to 1 foot apart each way, and in time the foliage covered the entire bed. Every autumn the bed received a top-dressing of well-rotted manure, and the plants improved in vigour every season. I had tried this *Aquilegia* without success, but I had always purchased plants, and as a rule they were miserable specimens in pots. After my visit to Dr. Stuart I adopted his method, and I was rewarded with a grand lot of plants, which grew well for several years. Newly ripened seed sown at once where the plants are to flower seems to solve the supposed difficulty of the successful cultivation of this exquisite Columbine. George M. Taylor, Mid-Lothian.

FRUIT-EATING BIRDS.—Various kinds of fruit-eating birds have multiplied to a large extent during recent years, as the winters have been so mild that they have not been starved out. Particularly numerous are the tomtits, which did much damage to choice Apples and Pears last autumn. I write to suggest, both to growers and gardeners, that it is a good plan to plant plots of the common Sunflower near to the trees. Tits are very fond of the seeds, which draw the birds from the fruits. I think also that if cheap soup-plates or dishes were placed near the trees and kept filled with water they might prevent some damage to the fruit crops. George Bunyard, Maidstone.

CYANIDING FOR MEALY BUG.—Mr. Fulton (p. 151) says that 130 per cent. sodium cyanide is a meaningless quantity, but now that I have used it, I can assure him that it has proved full of meaning to all exposed bugs and other insect life in the houses in which it has been used. I have treated two vineries, one before cleaning and one after. All the bugs that could be seen were dead, but we found some alive under the bark, and a few have commenced to move on the

vines first treated, which shows the necessity of cyaniding several times at short intervals, as I am certain no strength of gas will destroy the bug or eggs which are in small holes or cracks. I am now going over the rods with a strong wash, and may stypitic any holes that can be seen. It is somewhat strange that some writers have found it necessary to use the cyanide for so many years as they say they have done, judging by the results they have obtained, as once houses and plants are free of bug it cannot come annually in the same way as fly, thrip, or spider. I was surprised to read that Mr. Colville's plants in an adjoining house had suffered, as I have had no trouble of that sort. Certainly this looks ominous for any attempt to cyanide the said houses. Mr. Colville has perhaps not tried the same formula as used by those who have found it harmless to all plants. A. Shakelton, Forde Abbey Gardens, Chard.

FEBRUARY RAINFALL (see p. 157).—The rainfall during the month of February, which *Southern Grower* states is known as "fill-dyke," differs peculiarly in different years. Mr. Cook, writing from Sandringham Gardens, on March 4, states "but 21.68 inches was registered during the whole of last year, and January and February this year are on a par with last year. In January 1.59 inch fell, and in February 1.29 inch, so we have no 'fill-dyke' February here; in fact, the springs and our water supply have never been so low." Compare this with our records at Swanmore, where last year the total rainfall was 38.51 inches, while in February this year 6.38 inches fell. In February, 1910, we registered 5.15 inches, in 1912 3.56, and a total for the latter year of 46.01, which was 16 inches more than the average for South Hants. In February this year we had but seven dry days. We have, therefore, much more rainfall than in *Southern Grower's* district. E. M., Swanmore Park Estate, Bishops Waltham.

—Seeing that *Southern Grower* records a rainfall in February of 4.02 inches in his district, and several others 3.0 inches or just over, I am anxious to know if our fall (5.24) is a record for this part of the country. Most of the rain fell during the second and third weeks. On each day of the 8th and 21st we registered 0.87 inch, and 0.75 on the 11th. The most rain fell on these three days. On seventeen out of the twenty-eight days in the month we registered rain, and this is remarkable, seeing that we seldom get the heaviest of the rain, as Woldingham is on the top of the Surrey Hills, 880 feet above sea level. As a rule the heaviest storms seem to occur in places of a lower elevation. Thos. Newman, The Gardens, Wistler's Wood, Woldingham, Surrey.

NARCISSUS FLY.—At the meeting of the R.H.S. Scientific Committee on February 24, reported in your issue of March 7, a *Narcissus* bulb was shown containing larvae of the small *Narcissus* fly (*Eumerus lunulatus*), and it was stated that this fly is apparently very destructive to *Narcissus* bulbs in certain seasons. It is very desirable that this point should be thoroughly investigated under proper scientific conditions. Until this is done we shall be in a state of harassing uncertainty, but meanwhile, *Daffodil* growers may be relieved to think, as I do, that this opinion will perhaps prove to be mistaken. I have had experience of this fly (or *Eumerus strigatus*) in varying conditions since 1907. The conclusion I have come to at present is that the larvae do not attack a healthy bulb, and are never the direct cause of the injury. I have, for instance, taken up this spring a dozen or more *Daffodil* bulbs which contained *Eumerus* larvae, and in every one of them there was also a *Merodon* grub. In other years I have had bulbs containing *Eumerus* larvae only, but there has always been reason to believe—and I recorded it at the time—that the actual damage to these bulbs had been caused by a *Merodon* grub which had migrated or pupated, or by some fungus pest, and that the *Eumerus* larvae were feeding, not on the living tissue, but on the excrement of the *Merodon*, or on the dead and rotting substance. In the case mentioned by the secretary of the Scientific Committee, of *Eumerus* larvae being found in the rhizomes of *Iris* (which were from my plants), the injury was directly

caused by the fungous-bacterial Iris disease, and it is practically certain that the larvae came from eggs deposited in the rhizomes after the tissues had already gone soft and rotten from the disease. In fact, I feel satisfied that these Eumerus larvae are scavengers. *A. J. Bliss.*

THE N.E.H.S. (see p. 207).—I agree with some of the things my friend the Rev. Bernard Hall says in his letter to you, but has he done a wise or a kindly thing in rushing into print at the present moment? I think the new arrangements might at least have been given a year's trial. Mr. Hall, in all his speeches which I heard while he was Secretary, went out of his way, I thought, to belaud the R.H.S.—its kindly interest, its sympathy, its valuable help (which I never saw), etc., etc. How does this tally with his "Thirdly" in his letter to you? *W. Cuthbertson.*

JOURNEYMAN GARDENERS' WAGES.—Some years ago, shortly after the B.G.A. was started, one of its promoters was staying for a time with me, and was holding forth in his usual manner about shortening the hours of labour and increasing the

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 24.—There was a large exhibition on the occasion of the fortnightly meeting held on Tuesday last in the Vincent Square Hall, Westminster. Forced flowering trees and shrubs occupied the greater part of the space under the north wall, and the visitor on entering the building was confronted by a charming scene of floral beauty. Other notable exhibits before the Floral Committee were groups of Ferns, Carnations, Roses, Clematis, Hippeastrums, Pelargoniums and hardy flowers. This Committee recommended three Awards of Merit to novelties.

The Orchid Committee awarded nine Medals to collections and recommended one First-class Certificate and two Awards of Merit.

The Narcissus Committee awarded five Medals to groups and four Awards of Merit to novelties.

The only exhibit of importance in the Fruit and Vegetable Section was a collection of vegetables shown by Messrs. SUTTON AND SONS, Reading.

those of *R. argenteum*, and have a similar showy pink stigma. They are, however, larger and more cylindrical, and in most of the blooms the stamens are either completely absent or curiously aborted. The plant is hardy, and the blooms of *R. argenteum* shown with it had been cut from out of doors, but the specimen which obtained the award had been flowered in a cold house to keep the bloom in the best condition. Shown by Miss MANGLES, Seale.

Soldanella pusilla alba (see fig. 100).—The pure white, solitary, nodding, and prettily fringed flowers of this dainty little Alpine were much admired. Except in colour, it exactly resembles the type, having the smallest of kidney or heart-shaped leaves in close rosettes and flower stems only 2 or 3 inches high. Shown by Messrs. T. S. WARE, Ltd., Feltham.

Trillium rivale.—This, the smallest of the American Wood Lilies, has a small, creeping rootstock, and bears its erect cup-shaped flowers on slender stems about 3 inches high. The blooms scarcely exceed an inch in diameter, and are white, richly and somewhat variably dotted over with rose. Ternate-stalked bracts are borne about 2 inches below the flower. Shown by Mr. JAMES BOX, Lindfield.

OTHER NOVELTIES.

Rhododendron violaceum, Forrest's No. 5,876.—This new Alpine Rhododendron, from the Lichiang Range of Western China, was represented by a pretty flowering specimen only 3-4 inches high, raised from seed sown in 1911. As a garden plant it was thought too close to *R. intricatum*, which in foliage it somewhat resembles, though the leaves are glossier, narrower and recurved at the margins. The flowers, however, are very different, exceeding an inch in diameter, expanding almost flat, and having the segments cut almost to the centre. The filaments of the stamens are spreading, and as long as the corolla.

Rhododendron Keiskii, a little-known Japanese Alpine Rhododendron, with flowers of a pale lemon yellow, borne freely on plants only a few inches high, raised from seed in 1911. These, with flowers of *R. oleifolium*, were shown by E. J. P. MAGOR, Esq., St. Tudy.

Primula redolens.—A new Chinese Primrose collected by Mr. F. Kingdon Ward for Messrs. Bees, Ltd. It belongs to the *nifruticosae* section, and in foliage much resembles its congener *P. Forrestii*, appearing indeed softer and more hairy. Umbels of 12 to 20 flowers are borne on stout 6 to 9 inch stalks. They vary from white to pale pink in colour, in one case being splashed with purple, and all possess a small yellow eye. Shown by Professor BAYLEY BALFOUR, Botanic Gardens, Edinburgh.

CULTURAL COMMENDATIONS.

The award of a Cultural Commendation was made to Mr. W. BAIN, gardener to Elizabeth Lady Lawrence, for The Knoll variety of *Lapageria rosea*. This fine variety has already received an Award of Merit, but remains very little known. In colour it is hardly so deep as in the Nash Court variety, but the flowers are of large size and substance and quite distinct by reason of the open bell-shape given to the perianth by the spreading, recurving tips of the broad inner segments.

A Cultural Commendation was also awarded to Mr. EMERTON, gardener to Earl Brownlow, Grantham, for *Brownea grandiceps*, a leguminous stove shrub, with handsome pinnate drooping foliage and large, dense, flat heads of bright carmine flowers. The plant had been in cultivation at Grantham for twenty-four years, and flowered in 1913 for the first time. The species was awarded a First-class Certificate by the R.H.S. Floral Committee in August, 1866.

GENERAL EXHIBITS.

MESSRS. J. HILL AND SON, Edmonton, were awarded a Silver-gilt Flora Medal for a group of well-grown Ferns, the most striking feature being the tinted varieties, that were in their full beauty with the new season's fronds. The finer of these were *Adiantum scutum roseum*, *Lastrea erythroa*, *Brainea insignis*, and *Blechnum brasiliense*.

MESSRS. JAMES VEITCH AND SONS, Chelsea, showed a magnificent group of forced shrubs in flower, for which a Silver-gilt Flora Medal was awarded. This splendid exhibit had in the

FIG. 100.—*SOLDANELLA PUSILLA ALBA*.
(See Awards by R.H.S. Floral Committee.)

rate of pay, and sadly wanted me to join the movement. This I refused to do on any account, and was told that, whether I did or not, they would get a following. I said I had no doubt about that, and the following would include all the aspiring young men who could be found any day in the week with their hands washed and their coats on and the handle of the door in their hand, waiting for the "bell to ring," and I wish you joy of them, for they will never be gardeners. Gardeners are born, not made, and the man who is born to become a gardener knows nothing of hours, and is like cream—bound to get to the top. *T. Smith.*

—*H. H.* states on p. 189 what he considers a suitable wage for a man of my experience. I have long been trying to obtain a post with better wages, but without success. The reason I took this place was that I was told that if I made a good garden of it my wages would be considerably increased; when, however, I broach the subject the reply is always, "I can't afford it." I have thought many a time of giving up gardening and working as an unskilled labourer—I believe I should be better off. It's only the love of the garden that keeps me to it; the flowers are a greater joy to me than anything else. *C. H.*

At the three o'clock meeting in the Lecture Room a paper on "The Pruning of Shrubs" was read by Mr. Edwin Beckett.

Floral Committee.

Present: H. B. May, Esq. (in the chair), Messrs. C. E. Shea, H. J. Jones, J. Dickson, G. Reuthe, C. R. Fielder, J. T. Bennett-Poë, C. Dixon, A. Turner, W. Bain, R. C. R. Nevill, W. H. Page, A. A. Dorrien Smith, J. W. Moorman, R. Hooper Pearson, T. Stevenson, J. Green, F. W. Harvey, J. F. McLeod, J. Jennings, W. Howe, C. Blick, B. Crisp, W. A. Bilney, W. B. Cranfield, G. Gordon, R. C. Notcutt, C. E. Pearson, F. Page Roberts, E. H. Jenkins, G. Paul, J. Hudson, C. T. Drury, and W. J. Bean.

AWARDS OF MERIT.

Rhododendron argenteum.—This is a massive-flowered seedling variety of *R. argenteum*, with noble foliage and handsome flowers. The leaves, about 12 inches long by 3 inches broad, are richly silvered below and are held horizontal on stout stalks. The truss of flowers shown was 9 inches across and carried twenty-four large bells of a pure creamy-white, with a small purple patch at the bottom of the bell. The flowers are close to

centre a large number of Wistarias set off by standard Laburnums, Prunus triloba and Exochorda grandiflora, and then a row of the white Viburnum Opulus leading on to masses of Cerasus Pseudo-cerasus, Pyrus floribunda, Prunus triloba and others of this kind. As a separate exhibit Messrs. Veitch showed greenhouse Rhododendrons, Azaleas, Boronia megastigma and varieties of Hippeastrums.

Messrs. W. CUTBUSH AND SON, Highgate, staged a large group of forced shrubs, the collection embracing Acacias, Wistarias, Viburnums, Genistas, Magnolias, Laburnums and Azaleas. This firm also showed Alpines and Carnations Scarlet Glow, Lady Ingestre, pink, Mrs. Lucy Mackinnon, scarlet, and others. (Silver Flora Medal.)

Messrs. JOHN PEED AND SON, West Norwood, were awarded a Bronze Banksian Medal for a bank of forced shrubs, principally Rhododendrons, relieved with ornamental-leaved Maples.

Mr. L. R. RUSSELL, Richmond, showed, as at the last meeting, varieties of large-flowered Clematises, for which a Silver Banksian Medal was awarded.

Messrs. WM. PAUL AND SON, LTD., Waltham Cross, showed pot plants of the fragrant Choisya ternata, for which a Silver Banksian Medal was awarded. The plants were carrying fine trusses of the pretty white blooms, and were suitable for arranging on the conservatory stages or for other decorative uses.

Messrs. R. GILL AND SONS, Tremough, Cornwall, again contributed a display of Rhododendrons, for which a Bronze Banksian Medal was awarded. Trusses of Rhododendron Nuttallii were the most conspicuous in the collection, the large cream-coloured bells having a yellow tinting in the interiors.

Messrs. H. J. JONES, LTD., Hither Green, Lewisham, showed bunches of zonal-leaved Pelargoniums. Pink Pearl (pink, with a white eye), Charles Bullen (salmon-pink), and Mrs. West, a variegated salmon and white flower, are three new varieties of merit. The variety Will, of crimson-scarlet colour, had pips measuring 3 inches across.

An exhibit of these flowers was also shown by Messrs. H. CANNELL AND SONS, Eynsford.

Mr. A. H. COLE, Swanley, Kent, exhibited Star Cinerarias of an early strain, and a crimson sport of Pelargonium Paul Crampel, the novelty being a good winter bloomer as well as a fine summer bedding variety. (Bronze Banksian Medal.)

Messrs. H. B. MAY AND SONS, Edmonton, were awarded a Silver Banksian Medal for Pansies, Violas, Cinerarias, Cyclamens and Clematis.

Mr. CHAS. TURNER, Slough, exhibited miscellaneous greenhouse flowering plants. Specimens of Clivia miniata were exceptionally good, and there were also finely-flowered Staphylea colchica, Azaleas, Acacias, with Roses and Ferns. (Bronze Banksian Medal.)

Messrs. WILLS AND SEGAR, South Kensington, showed flowering plants of Mignonette, Gerberas, Azaleas, Clivia and Cinerarias, for which a Bronze Banksian Medal was awarded.

A Silver Banksian Medal was awarded to Viscountess KNUTSFORD, Royston, for Hippeastrums (Amaryllis).

Mr. GEORGE PRINCE, Oxford, was awarded a Silver Flora Medal for Roses. The fine pillar variety Tausendschön was shown remarkably well, and there were good blooms of W. Shean, Liberty, Mrs. J. H. Welch, Mrs. W. J. Grant and Mme. Edouard Herriot.

Messrs. W. AND J. BROWN, Stamford, showed Roses. The new pillar variety, Mrs. Rosalie Wrinch, has large, single rose-coloured blooms. (Bronze Banksian Medal.)

The following were exhibitors of Carnations:—Mr. H. BURNETT, Guernsey (Silver Flora Medal); Messrs. STUART LOW AND CO., Enfield (Silver Banksian Medal); Mr. C. ENGELMANN, Saffron Walden (Bronze Flora Medal); Messrs. ALLWOOD BROS., Wivelsfield, Haywards Heath (Bronze Banksian Medal); Messrs. W. WELLS AND CO., LTD., Mersham; and Messrs. YOUNG AND CO., Cheltenham (Silver Banksian Medal).

Messrs. J. PIPER AND SON, Bayswater, contributed the largest of the numerous rock gardens staged on this occasion. As will be seen on reference to fig. 99, it was

a large and bold exhibit, well arranged and not over planted. The top was crowned with a mass of the fine rose-coloured Azalea Benegeri, with Bamboos and other shrubs as a background. At the lower part were excellent plants of Primula denticulata, Gentiana verna, Primula Juliae and other Alpines, whilst a depression at the other end was massed with Primula japonica. In nooks and crannies of the rocks were set fine plants of Shortia uniflora, Viola gracilis, Anemones and other species. (Silver-gilt Banksian Medal.)

Messrs. BARR AND SONS, King Street, Covent Garden, were awarded a Bronze Flora Medal for a rockery, which was planted with seasonable flowers, such as Muscari, Anemone blanda taurica, Narcissus Cyclamineus, Fritillarias and Anemone Pulsatilla.

Mr. MAURICE RICHARD, Christchurch, Hampshire, had one of the best exhibits of Alpines arranged as a flat rock garden, on which Anchusa myosotidiflora, Primula rosea grandiflora and Primula cashmeriana Riverslea, a deep lavender-coloured form, were especially noticed. (Silver Banksian Medal.)

Messrs. JOHN WATERER, SONS AND CRISP, LTD., Twyford, showed Alpines on a rockery and flowering shrubs, including Rhododendron caucasicum, R. Handsworth Early Scarlet, Andromeda (Pieris) japonica and Prunus Pisartii. (Bronze Banksian Medal.)

Rock gardens were also exhibited by Messrs. J. CHEAL AND SONS, Crawley (Bronze Banksian Medal); Mr. A. HEMSLEY, Crawley; The Misses HOPKINS, Shepperton (Bronze Banksian Medal); Mr. CLARENCE ELLIOTT, Stevenage (Bronze Banksian Medal); and Messrs. WHITELEGG AND PAGE, Chislehurst (Bronze Flora Medal.)

Messrs. G. and A. CLARK, LTD., Dover, showed their fine Primulas Cloth of Gold and Avalanche in an exhibit of hardy flowers. (Bronze Banksian Medal.)

Mr. REGINALD PRICHARD, West Moors, Dorsetshire, exhibited Alpines in pots. Hardy flowers were also shown by Mr. G. W. MILLER, Wisbech; BURTON HARDY PLANT NURSERY; GUILDFORD HARDY PLANT NURSERY; Messrs. BAKERS, Wolverhampton (Bronze Banksian Medal); Mr. GEO. REUTHE, Keston (Bronze Banksian Medal); Mr. JAMES BOX, Haywards Heath; Messrs. T. S. WARE, LTD., Feltham (Bronze Banksian Medal); and Messrs. THOMPSON AND CHARMAN, Bushey, Hertfordshire (Bronze Banksian Medal.)

Messrs. RAMSBOTTOM, Geashill, Ireland, again showed flowers of their first strain of St. Brigid Anemones.

Messrs. CARTER, PAGE AND CO., London Wall, exhibited Violas and Pansies, also spikes of the beautiful, light-blue coloured Nemophila insignis.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair, and Messrs. Jas. O'Brien (Hon. Sec.), Gurney Wilson, De B. Crawshaw, W. Bolton, R. Brooman White, S. W. Flory, W. H. White, E. H. Davidson, J. Cypher, J. Charlesworth, H. G. Alexander, J. E. Shill, A. McBean, W. Cobb, F. M. Ogilvie, R. G. Thwaites, W. H. Hatcher, Stuart Low, R. A. Rolfe, T. Armstrong, W. P. Bound, A. Dye, Sir Harry J. Veitch, and Sir Jeremiah Colman, Bart.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontioda Zenobia (see fig. 101) (*Ada Charlesworthii* × *Odontoglossum percultum*) from F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth). A very fine and distinct hybrid, and a worthy production in every way. The spike bore two flowers of circular outline, the segments being also broad and of fine substance, in colour deep reddish-claret with a violet tint; the broad lip expanded in front, deep rose with yellow crest.

AWARD OF MERIT.

Dendrobium superbum Huttonii Southfield variety, from W. WATERS BUTLER, Esq., Southfield, Edgbaston (gr. Mr. Jones). A large form of the type originally introduced by Messrs. Jas. Veitch and Sons through their collector Hutton, and with more colour in the lip. Flowers white, the greater part of the lip dark violet.

Sophro-Laelio-Cattleya Niobe Orchid Dene variety (*L.-C. Gottoiana* × *S.-L. Felicia*) from

E. H. DAVIDSON AND CO., Orchid Dene, Twyford. A charming flower, of good size and shape, and one of the darkest of *Sophrontis* crosses. Sepals and petals bright rose-purple. Lip deep claret-red. The flower is of fine substance.

CULTURAL COMMENTATION.

To Mr. W. H. WHITE, Orchid grower to Elizabeth Lady Lawrence, Burford, for a grand specimen of *Platyclinis glumacea*, with about 100 sprays of white, fragrant flowers.

To Mr. COLLIER, gr. to Sir Jeremiah Colman, Bart., for *Odontioda Bradshawiae* with 119 flowers.

GENERAL EXHIBITS.

Messrs. SANDER AND SONS, St. Albans, staged a very fine group, for which a Silver-gilt Flora Medal was awarded. At the back were large numbers of Messrs. SANDER's original type of *Cymbidium insigne*, with tall spikes of white flowers with rose-purple markings, several *C. Gottianum*, and *C. Pauwelsii*, *C. Wiganianum* and some fine specimens of *C. eburneum*, one of which bore 30 flowers and buds. With them were good specimens of hybrid *Odontoglossums*, *Laelio-Cattleyas* and other hybrids. Rare species noted were *Coelogyne Lawrenceana*, *C. speciosa*, *Vanda Watsonii*, *V. suavis*, *Megaclinium maximum*, *Cirrhopetalum Masterianum*, *Maxillaria Fletcherianum*, *M. lepidota*, various *Masdevallias* and *Dendrobiums*.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), was awarded a Silver Flora Medal for an interesting group containing several hybrids raised at Rosslyn, including two very fine forms of *Cymbidium Low-grinum* (*Lowianum* × *tigrinum*), the new *Brasso-Cattleya William Pitt* (*C. Octave Doin* × *B.-C. Marie*), a finely shaped light-rose coloured flower; *Laelio-Cattleya Avoca* (*L. Latona* × *C. Trianae* var.), and some hybrid *Odontoglossums*, and *Odontiodas*. *Cymbidium Lady Colman* and *C. eburneum-Lowianum* were well shown, together with a good selection of *Cypripediums*, *Miltonia Warszewiczii*, and a well-flowered plant of the rare *Eulophiella Elisabethae*.

Messrs. CHARLESWORTH AND CO., Hayward's Heath, were awarded a Silver Flora Medal for a group of finely-grown Orchids, among which were noted a showy set of hybrid *Odontoglossums*, several fine *O. crispum*, the most remarkable being the pretty *O. c. Queen Maud*, the wax-like segments being distinctly spotted with purple, as in *O. c. Lady Jane*. The *Odontiodas* included a very deep scarlet *O. Charlesworthii*, *O. Cooksoniae*, *O. Bradshawiae*, *O. Lutetia* and others. Good *Laelio-Cattleya Haroldiana*, *Brasso-Cattleyas*, and *Dendrobiums*, and their fine *Miltonia Charlesworthii*, were effectively displayed, the front of the group being of profusely-flowered *Sophrontis grandiflora* and *Oncidium concolor*.

Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, were awarded a Silver Flora Medal for a group, principally hybrids, the centre being of very handsomely blotched hybrid *Odontoglossums* flowering for the first time. *O. Royal Purple* (*illustris* × *Edwardii*) was a pretty flower of a rich violet-purple colour. The *Odontiodas* included a brilliant scarlet form of *O. Keighleyensis*, *O. Bradshawiae*, *O. Leeanaum* and others. Various hybrid *Dendrobiums*, varieties of *D. nobile* and its pure white variety *virginale*, *Miltonia St. Andre*, *M. Bleuana*, good *Cypripediums*, *Cattleyas* and *Laelio-Cattleyas*, some of them showing their first flowers, were also noted.

Messrs. STUART LOW AND CO., Bush Hill Park, and Jarvisbrook, Sussex, were voted a Silver Flora Medal for a group in which the *Dendrobiums* were a pleasing feature. These included several of the *D. Jamesianum* class, *D. crepidatum*, *D. Wardianum*, *D. crassinode album*, *D. Brymerianum* and *D. fimbriatum oculatum*, arranged with *Cymbidiums*, *Oncidium sarcoades*, *Phalaenopsis Aphrodite* and a fine variety of *P. intermedia Portei*; some well-flowered *Cattleya Schröderae*, *Laelia Jongheana*, *Odontoglossums* and *Brasso-Cattleyas*. Among the *Odontiodas* was a distinct hybrid between *O. Rolfeae* and *C. Noezliana*, with broad rich red flowers of the *O. Charlesworthii* class.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Surrey (gr. Mr. Collier), was awarded a Silver Banksian Medal for a selection of very fine specimens of *Odontioda Bradshawiae* and *O.*

Vuystekeae, nine plants of which bore between them 750 brightly-coloured flowers; one specimen of *O. Bradshawiae* with 119 scarlet flowers and buds securing for the grower a Cultural Commendation. The new *Odontioda Colmanii* (*Odontioda Bradshawiae* × *Odontoglossum amabile*), flowering for the first time, was also shown. The flower adhered closely to *Odontoglossum*, being not unlike a richly-blotched *O. crispum*.

Messrs. J. CYPHER AND SONS, Cheltenham, staged an effectively arranged group of good *Dendrobium*s, *D. Thwaitesii* Veitch's variety being still the best deep yellow, with maroon eye. *D. nobile* Perfection, *D. rybens grandiflorum*, *D. Dalhou-nobile*, *D. Apollo grandiflorum* were among the best. With them were *Angraecum sesquipedale*, *A. citratum*, *Masdevallia Gargantua*, a very dark *M. Chimaera*, *Phalaenopsis Sanderiana*, *Sarcochilus Fitzgeraldii*, *Oncidium concolor*, *Epidendrum xanthimum* and a good selection of *Cypripedium*s.

Messrs. FLORY AND BLACK, Orchid Nursery,

cluding the spotted *O. Pescatorei* Pitt's variety, *Cymbidium eburneo-Lowianum* and the pale-yellow variety concolor and a large form of the pure white *Cattleya Brenda*.

R. G. THWAITES, Esq., Chessington, Streatham, sent a selection of hybrids, among which were *Odontoglossum Newlingii* (*Ossulstonii* × *cirrhosum*), *O. Vuylcirra* (*Vuystekeae* × *cirrhosum*) and *Odontioda Sanderiae*.

PANTIA RALLI, Esq., Ashted Park, Surrey, showed *Odontoglossum Aureola* of unrecorded parentage, a fine pale canary-yellow flower with some red-brown blotches on the lip—closely resembling *O. Canary* shown by Mr. RALLI previously, and illustrated in *Gardeners' Chronicle*, fig. 23, p. 44.

E. R. ASHTON, Esq., Broadlands, Tunbridge Wells, showed *Miltomia vexillaria* Lyoth (*chelseiense* × *Memoria* G. D. Owen), a large rose-pink flower with distinct rosy-crimson mask on the lip.

W. WATERS BUTLER, Esq., Southfield, Edgbaston (gr. Mr. Jones), showed *Cattleya Tityus* Southfield variety (*Octave Doim* × *Enid*), a large

AWARDS OF MERIT.

Narcissus Syphax (for garden and cutting).—A yellow *Jonquilla* hybrid of typical shape and excellent appearance, which, however, possesses but slight perfume.

N. Tita (for garden and cutting).—An exceedingly beautiful *Incomparabilis* variety. The perianth segments are very long and firm, and the moderately-sized corona has a fiery orange-rim. This large and bold flower is well set upon stout stalks.

N. Sunrise (for cutting).—As shown, the flowers of this medium-sized *Barrii* variety do not hold themselves sufficiently erect to be an ideal *Narcissus* for vases, but they appeared to be not fully developed. The colour scheme is, however, charming, and the nearly white of the overlapping perianth segments shades into pale yellow around the orange corona, which has a very bright rim. The round flowers have plenty of substance, and should travel well. These three varieties were shown by Mr. ALEX. M. WILSON.

N. Eastern Maid (for show).—A very chaste and beautiful *Leedsii* variety. The large, full perianth segments are of pale yellow colour, and surround a symmetrical corona of a deeper shade of the same colour. Shown by Messrs. R. H. BATH, LTD.

GENERAL EXHIBITS.

Messrs. BARR AND SONS, Covent Garden, London, contributed a large collection of cut *Narcissi* in which unnamed seedling Trumpet varieties were the chief feature. Of these, N.X. 1,997, a bicolor with a long, yellow trumpet and broad, overlapping perianth segments, should prove to be a popular flower. In *Corallina*, a *Leedsii* variety, the shrimp-pink corona standing out from the pure white perianth segments is exceedingly attractive. *Golden Arrow* is a *Cyclamineus* hybrid of large size but typical form and rich yellow colour. Of the new *Barrii* varieties in this collection the chief place was taken by *Isis*, in which the broad, overlapping primrose-yellow segments provided a splendid foil to the brilliant corona. Many standard varieties of great merit were shown, and a large number of the Trumpet variety King Alfred occupied the central position in this superb collection of Daffodils, gathered out-of-doors in Messrs. BARR's Cornish garden. (*Silver-gilt Banksian Medal*.)

Mr. ALEX. M. WILSON, Showell, Bridgwater, Somerset, showed fewer but equally meritorious blooms. The chief attraction was centred in the three new sorts which were selected for the coveted Awards of Merit. Most of the remaining blooms were unnamed seedlings, principally *Leedsii* and *Tazetta* hybrids. Of the former, one with a very widely expanded corona held the eye, and the latter type included several with brilliantly coloured coronas, giving the impression of cluster-flowered *Poeticus*. Of the named sorts, *Vivandière*, a *Barrii* which has "paper-white" perianth segments and a vivid orange rim to the yellow corona, was startlingly beautiful. *Beryl*, a *Cyclamineus* hybrid, and *Averil*, a bicolor Trumpet possessing a very long, yellow tube, were also very praiseworthy. (*Silver-gilt Banksian Medal*.)

Messrs. CARTWRIGHT AND GOODWIN, Kidderminster, specialised in *Tazetta* hybrids and Trumpet Daffodils. Of the former, the best were *Elvira* and *Aspasia*, and chief amongst the Trumpets were *Fairy*, *Supremacy* and *Gold Wolf*, another rich yellow-coloured sort, but with a much shorter and broader trumpet. *Chryse* was the largest *Jonquilla* hybrid in the show, and *Ivorine*, a *Leedsii* bloom with a flattened, fluted corona, had a very uncommon appearance. (*Silver Flora Medal*.)

Messrs. R. H. BATH, Ltd., Wisbech, included in an attractive group of Daffodils *Princess Ena* and *Marie Hall*, two delightful and similar *Incomparabilis* varieties, *Flame*, a vivid-eyed *Barrii*, and *Golden Sunrise*, a rich yellow, widely expanded Trumpet bloom. These were flanked by a large number of *Scilla* and *Chionodoxa* blooms and many Tulips in bowls of fibre. The outstanding Tulip varieties were *William Copeland* and *Valentine* (Darwins), *Le Rêve*, *Rose of Holland*, and *Prince of Austria*. (*Silver Flora Medal*.)

Mr. CHRISTOPHER BOURNE, Simpson, Bletchley, also showed an attractive group of Daffodils

FIG. 101.—ODONTIODA ZENOBIA: SEPALS AND PETALS COLOURED REDDISH-CLARET WITH A VIOLET TINT. (R.H.S. First-class Certificate on Tuesday last.)

Slough, were awarded a Silver Banksian Medal for a group of showy hybrids, the central plant being the richly-coloured *Laelio-Cattleya Invincible Orama*, which secured an Award of Merit in 1912. Also the original coloured form of *Laelio-Cattleya Frederick Boyle*, and the newer blush-white type, *L.-C. Violetta* of fine colour, and several new *Laelio-Cattleya*s of attractive colour. At the back were a selection of *Odontoglossum*s, one spotted form of *O. Pescatorei* being specially good. Others noted were *Lycaste Skinneri alba*, two specimens of the pretty *Disa sagittalis*, and some *Brasso-Laelio-Cattleya*s.

Messrs. HASSALL AND CO., Southgate, were awarded a Silver Banksian Medal for a group in which were some fine varieties of *Cattleya Schröderae* and *Odontoglossum*s, arranged with the bright-red *Renanthera Inschootiana*, very finely-coloured *Laelio-Cattleya luminosa*, *Maxillaria Sanderiana* and *Lycaste Skinneri*.

Messrs. J. AND A. McBEAN, Cooksbridge, staged a small group in which were a very bright-red *Oncidioda Cooksoniae*, some finely-coloured *Odontioda*s, good *Odontoglossum*s, in-

and finely-formed rose-coloured flower with broad ruby-red lip with a rich yellow disc, and *Dendrobium superbum Huttonii giganteum*. (See Awards.)

E. H. DAVIDSON AND CO., Orchid Dene, Twyford, showed the large, bright-red *Odontioda Bradshawiae* Borlases variety and *Sophran-Laelio-Cattleya Niobe* Orchid Dene variety. (See Awards.)

Sir JOHN EDWARDS MOSS, Roby Hall, Torquay, sent a flower of a *Laelio-Cattleya* curiously malformed, the upper sepal being very short and distinctly divided, and the lateral sepals rudimentary and twisted.

Narcissus and Tulip Committee.

Present: E. A. Bowles, Esq., in the chair; the Revs. C. T. Digby and Joseph Jacob, Messrs. J. T. Bennett-Poë, W. B. Cranfield, Herbert Smith, P. D. Williams, Alex. M. Wilson, W. W. Fowler, J. D. Pearson, Walter T. Ware, P. Rudolph Barr, G. Reuthe, F. Herbert Chapman, G. W. Leak, Charles Dawson, Wm. Poupert, Christopher Bourne, C. Lemesle Adams, and Chas. H. Curtis (hon. secretary).

MARKETS.

COVENT GARDEN, March 25.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

Cut Foliage, &c.: Average Wholesale Prices.

a. d. s. d.	a. d. s. d.
Adiantum Fern (Maidenhair), best, per doz. bunches .. 7 0-8 0	Croton foliage, vs., doz. bunch. 12 0-15 0
Agrostis (Fairy Grass), per doz. bunches .. 2 0-4 0	Cycas leaves, per doz. .. 3 0-12 0
Asparagus plumosus, long trails, per half-dozen .. 1 6-2 0	Eulalia japonica, per bunch .. 1 0-1 6
— medium, doz. bunches .. 12 0-18 0	Moss, gross bunches .. 6 0 —
— Sprengeri .. 6 0-12 0	Myrtle, doz. bnchs. English, small-leaved .. 6 0 — — French .. 1 0 —
Carnation foliage, doz. bunches .. 3 0-5 0	Smilax, per bunch of 6 trails .. 1 6-1 9

French Flowers.

a. d. s. d.	a. d. s. d.
Anemones, double pink, per doz. .. 1 0-1 3	Marguerites, yellow, per dozen bunches .. 1 9-2 0
— De Caen, per doz. bunches .. 1 6-2 6	Star of Bethlehem, per dozen .. 1 3-1 6
— Blue, per dozen bunches .. 1 6-2 0	Stock, white, per pad .. 5 0-7 0 — per doz. .. 2 6-3 0
Lilac white, per bunch .. 2 6-3 6	Violets, Parmas, large bunch .. 1 3-1 6
— mauve, p. bnch. .. 5 0-6 0	
Ranunculus, scarlet, per dozen .. 4 0-6 0	

Guernsey and Scilly Flowers.

a. d. s. d.	a. d. s. d.
Anemone fulgens, per doz. bnchs. .. 2 0-2 6	Narcissus, Poeticus, per dozen .. 1 6-1 9
Daffodils (Guernsey) per doz. .. 2 0-3 0	— Grand Primo .. 2 0-2 6

REMARKS.—Prices have a tendency to rise. Good English Daffodils and Tulips are scarce, especially the white varieties, but Darwin Tulips are gradually increasing in quantity and the demand for them is better. Irises are becoming more plentiful, but their prices remain firm. Roses are now becoming prominent on the salesmen's stands. Some fine blooms of Mme. A. Chateau, Mrs. Sharman, Crawford, E. J. Hill, Liberty and Richmonds are marketed by Mr. E. Rochford, of Cheshunt.

Those of newer colours, such as Sunrise, are to be seen on Mr. Beckwith's stands. Supplies of Lily-of-the-Valley and Lilium Harrisii are sufficient for the demand, whilst L. lancifolium rubrum and album are more plentiful and the quality is better. Stephanotis is the latest subject arriving from Guernsey. Narcissus and Daffodils from Guernsey and Scilly are not so numerous as hitherto. Anemones, Freesias and Star of Bethlehem are all arriving in a good condition. The majority of flowers coming from the South consist of white Stocks, Star of Bethlehem and Anemones, the last in several varieties.

REMARKS.—Apples from Nova Scotia, California and Wenatchee are still obtainable in barrels and boxes. The best varieties are Almeria and Newtown Pippins. Cape fruits to hand this week per s.s. "Armada Castle," consisted of about 22,000 packages. The s.s. "Dunluce Castle" is also due with a consignment. The fruits consist of Black, White and Red Grapes, Plums, Pears, Peaches and Melons. English and Continental supplies of Black Grapes are decreasing, and forced Strawberries are a shorter supply. The market has received large consignments of excellent Asparagus from the Continent. Supplies of Peas are shorter, but Beans from Madeira and the Channel Islands are plentiful. There are good supplies of Seakale and Mushrooms. More Tomatoes are being received weekly from the Canary Islands, and a few home-grown Tomatoes are obtainable. Of Cucumbers there are large consignments daily. Forced Rhubarb is plentiful. English and Continental Onions are scarce and dear, but supplies of all ordinary vegetables are equal to the demand.—E. H. R., Covent Garden, March 25.

and Tulips. The former included Red Chief, a Barii bloom which has a very broad orange rim, a good unnamed seedling of the same class, and Noble and Adria, two very fine Incomparabilis varieties. Amongst the many Dutch and Darwin Tulips was a goodly group of the valuable yellow T. retroflexa. (Silver Banksian Medal.)

Messrs. CARTER AND CO., Raynes Park, massed a very large number of Sir Francis Drake, a sterling Trumpet Daffodil, and many clumps of German Iris in a very effective manner.

Mr. JAMES BOX, Lindfield, Sussex, showed such good varieties of Narcissus as Lucifer, Southern Star, and Homespun.

Messrs. SUTTON AND SONS, Reading, arranged a collection of Narcissus growing in bowls of fibre, which were fine examples of this method of culture.

Messrs. ROBERT SYDENHAM, Birmingham, contributed forced Lily-of-the-Valley, Anemones, and a small collection of Daffodils, amongst which The Sisterhood, a Leedsii bloom in which the sulphur-yellow corona is crinkled and frilled, was a chaste and pleasing flower.

Mr. G. W. MILLER, Clarkson Nurseries, Wisbech, also exhibited a collection of Daffodils.

Fruit and Vegetable Committee.

Present: J. Cheal, Esq. (in the chair), Messrs. J. Jeffries, W. Bates, F. Perkins, E. Beckett, H. Markham, Horace Wright, A. Grubb, A. R. Allen, Geo. Kelf, A. W. Metcalfe, G. Reynolds, W. E. Humphreys, A. Bullock, P. C. M. Veitch, Wm. Poupard, and C. G. A. Nix.

Messrs. SUTTON AND SONS, Reading, were awarded a Silver Banksian Medal for an exhibit of vegetables, comprising excellent specimens of Blood-Red Beets, Golden Ball Lettuces, White-tipped Radishes, Pride of the Market Cucumbers, Endive, Chicory, and Corn Salad or Lamb's Lettuce.

Mr. A. HEMSLEY, Crawley, showed fruits of the new Apple, Crawley Beauty, in a fresh and plump condition.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending March 25, 1914.
The First Unseasonably Cold Week for Eight Weeks.—This was the first cold week for eight weeks. During the course of it there did not occur a single unseasonably warm day or night; on the other hand, on only one day was the cold in any way unusual, and that was on the 20th inst., when the highest temperature in the thermometer screen was 36°. On the coldest night the exposed thermometer registered 12° of frost. The ground is at the present time 1° colder than is seasonable, both at 1 foot and 2 feet deep. Rain fell on each day of the week, and to the total depth of 2 1/2 inch. In fact, rain has fallen on all but one of the last eighteen days, and to the total depth of 4 inches—which is about double the average quantity for the whole month. Of that amount, 17 1/2 gallons has come through the bare soil percolation gauge, and 16 gallons through that on which short grass is growing, or nearly the whole of the rainfall of that period. Snow fell on each of the first five days of the week. On the 20th inst. the ground was for a short time covered to the average depth of 1 1/4 inches, and on the morning of the 19th inst. the flakes of snow which fell were for a short time of unusual size. The sun shone on an average for 2 1/2 hours a day, which is 1 1/2 hours a day short of the mean duration for the same period in March. On one day (22nd) the sun was shining brightly for eight hours; in contrast to this, on four days the sun shone for less than an hour a day. Light airs principally from some westerly point as a rule prevailed. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by as much as 13 per cent.—E. M.

DEBATING SOCIETIES.

WARGRAVE GARDENERS'.—At the last meeting of this society, three short papers were read by members, and each led to a capital discussion. The first was by Mr. T. Bachelor, of Shiplake Court Gardens, on "The Value and System of Stoking." Mr. R. Baker, of Park Place Gardens, read the second paper on "Figs—Outside and Under Glass." The methods of cultivation were described, and cultural directions were given. Mr. W. Clarke, of Bear Hill Gardens, followed with a third paper on "The Gesnera."

BURNLEY AND DISTRICT HORTICULTURAL.—A meeting of this society was held in the Mechanics' Institute on the 5th inst., Mr. Wilkinson Heap occupying the chair. The lecturer was Mr. M. Greenwood, of Rochdale, and his subject "Annals, Hardy and Half-hardy." Mr. Greenwood stated that annals may be described as everyone's flowers, for even those without greenhouses or frames could grow them. He recommended that the ground for planting annals should be cleared and dug in the autumn, and in February the land should be manured. The lecturer dealt specially with Sweet Peas, China Asters, Stocks, Marigolds and Chrysanthemums.

REMARKS.—Trade is much better than a few weeks ago; stocks in hand are not quite so large, and there have been fewer consignments. Prices are about the same as those of last week.—*Edward J. Newborn, Covent Garden and St. Pancras, March 25, 1914.*

GARDENING APPOINTMENTS.

Mr. J. Macdonald, Gardener to Colonel R. F. DUDGON, C.B., Gardens, Kirkcudbrightshire, and formerly in the Gardens at Drumlanrig, as Gardener to Colonel POLLOCK-MORRIS, D.S.O., The Craing, Kilmarnock.

Mr. E. Perkins, for 1 year and 10 months Foreman at Oldfield Brow Gardens, Altrincham, Cheshire, and previously at Garnons, Hereford, and Holdenby House, Northampton, as Gardener to Colonel HEYWOOD, Esq., Wootton Lodge, Ashbourne, Derbyshire.

Mr. H. Thrussell, for 4 years Foreman at Leyswood, Groombridge, Sussex, and previously Foreman at Althorp Park and Easton Neston, Northampton, as Gardener to J. S. SNEELGROVE, Esq., Kingswood, Tunbridge Wells, Kent.

Mr. R. H. Butcher, for 3 years at Church Hill, Harbledon, Canterbury, as Gardener to F. A. HAWLEY, Esq., Bunce Court, Otterden, near Faversham.

Obituary.

WILLIAM BRAND.—The death of Mr. William Brand occurred under sad circumstances at St. Aubyn's, Saffron Walden, on Monday last, at the age of 71. On the previous Tuesday his niece, Mrs. Byford, retired for the night at 11 p.m., leaving deceased sitting in front of the fire. Ten minutes later she heard him call, and on going downstairs found that he had fallen into the fire. His right shoulder was very badly burned, and after lingering a few days he died from shock. He was reaching to put out the gas when he caught his foot under the fender and fell. At the inquest a verdict of "Accidental Death" was returned. The deceased was in business for many years at Saffron Walden with Mr. George Webb (now of Cambridge), and traded under the style of Messrs. Webb and Brand. He retired about two years ago, when the business was purchased by Messrs. James Vert and Sons. The firm specialises in Hollyhocks.

ANSWERS TO CORRESPONDENTS.

APPLE BARK INFESTED WITH GREEN GROWTH: *J. S. E.* Your best plan will be to use a wash containing caustic alkali, and it would be necessary to make the application at once, or there may be a risk of injuring the expanding buds. The following formula may be regarded as a safe one for winter use:—Caustic soda (70 per cent.), 1 lb.; potassium carbonate (80 per cent.); soft soap, 10 oz.; water, 10 gallons. If the buds are already expanding it will be safer to add 15 gallons of water instead of ten. Spray again next winter, in February, at full strength.

BLACK HAMBURGH VINE: *S. J. T.* It is possible to grow very good Black Hamburgh Grapes in your district (Essex) without any fire heat in an ordinary season, but the vines having started the temperature should not be allowed to become too low. A temperature of 45° at night, or even 40° for a short time, will do no harm, and this you can generally manage to secure by closing the house early in the afternoon. A maximum day temperature of 85° to 90° in the shade is safe up to the time of stoning, when it is best, if possible, for the temperature not to exceed 80°. Berries of Black Hamburgh variety do not colour well in high temperatures.

DRAININGS FROM A STABLE: *Billerican.* Supposing the waste matter from the stable is pure urine, one part in ten will not be too strong for an occasional dose to fruit trees, which need assistance, including vines. A smaller proportion should be used for flowering plants, unless they are pot-bound, when it may be used at a greater strength. But it should not be applied to fruit trees after the fruits commence to colour. Re-pot the Orange trees; they will flower in time if you get the wood ripened.

DRESSING VINE RODS: *Anxious.* You do not state what method you adopted in cleansing the vine rods. Some merely wash them, whilst others remove all the outer bark and run the risk of damaging the inner surface. If you operated in the latter manner, and, as you say, the growths were rather badly ripened, the mixture containing Stockholm tar and soft soap may have been too strong, notwithstanding that the eyes were not painted. Unripe vines should be allowed to start naturally, after which fire heat may be applied. We do not yet consider it quite a hopeless case; the unripeness of the buds is sufficient to account for some of them not starting. Do not employ a high temperature at night.

GARDENING BOOKS: WORKS ON MELONS, PEACHES, AND FUCHSIAS: *B.* We do not know of any book dealing exclusively with the Melon, but *My Garden* contains five pages of cultural details on the Melon, also a couple of pages on the culture of the Cucumber, and *The Book of the Peach* is devoted entirely to the culture of the Peach under glass and out-of-doors. Both books may be obtained from our publishing department at 2s. 10d. and 2s. 9d. respectively, including postage. There are several old florists' works on the Fuchsia, but they are all out of print.

INSECT INFESTING CUPBOARD: *E. H. L.* The depredator is the larva of one of the so-called "bacon beetles" (Dermestes). Bake the articles to destroy any grubs they may contain, and paint the inside of cupboards with a strong solution of carbolic acid, taking care that the liquid is thoroughly worked into all the crevices and joints.

KAINIT: *Constant Reader.* The sample of manure you send us is not very pure, but it may contain the usual amount of potash found in kainit. It would be necessary, however, to make a chemical analysis in order to ascertain exactly how much potash was present. There is a considerable amount of insoluble matter in the manure. Cousins' *Chemistry of the Garden* contains much valuable information on the use of artificial manures in the garden. The book may be obtained from our publishing department, price 1s. 1½d., post free.

NAMES OF PLANTS: *W. H. M.* *Garrya elliptica*.—*A. W.* 1, *Pinus excelsa*; 2, *Pinus radiata*; 3, this appears to be a weak shoot of *P. excelsa*; send when in cone; 4, *P. Laricio*.—*A. T. H.* 1, *Phillyrea media*; 2, *Elaeagnus umbellata*; 3, *Cupressus pisifera filifera*; 4, *Thuja (Biota) orientalis*; 5, *Juniperus drupacea*; 6, *J. chinensis albo-variegata*; 7, *J. chinensis*.—*W. M.* 1, *Eupatorium trapezoides*; 2, *E. Wienmannianum*; 3, *Phyllanthus nivosus*; 4, *Senecio Kaempferi aureo-maculatus*.—*N. A. G.* 1, *Leucothoe Catesbaei*; 2, *Abies Pinsapo*; 3, *Atriplex Halimius*; 4, *Pieris floribunda*; 4, *Cassandra calyculata*; 6, *Cassandra angustifolia*; 7, *Rhododendron praecox*; 8, *Ribes sanguineum*; 9, *Rubus*; two No. 4 enclosed; No. 5 missing. —*A. C.* 1, *Gleichenia* sp.; 2, *Berberis Darwinii*; 3, *Cassinia fulvida*; 4, *Cupressus pisifera squarrosa sulphurea*; 5, *Cupressus pisifera plumosa*; 6, *Cupressus Lawsoniana* var. *amabilis*; 7, *Thuja orientalis*; 8, *Lupinus arboreus*.—*F. O.* 1, *Masdevallia simula*; 2, *Pleurothallis Scapha*; 3, *Octomeria diaphana*; 4, *Maxillaria lepidota*; 5, *Eulophia scripta*.—*F. P. H.* 1, *Cypripedium Krishma* (tonsum × *insigne*); 2, *Cypripedium Mons. de Curte* (Boxallii × *insigne*); 3, hybrid of *Cypripedium aureum*; 4, *Dendrobium Ainsworthii* (aureum × *nobile*); 5, *Adiantum hispidulum*.—*R. Y.* 1, *Polystichum setosum*; 2, *Gymnogramme tartarea*; 3, *Polypodium Dryopteris*; 4, *Scelopendrium vulgare*.—*W. J. S.* *Atriplex Halimius*.

NON-POISONOUS WEED KILLER: *W. B.* If you wish to employ a non-poisonous weed killer use common salt.

OAK LEAVES WITH GRUBS: *J. H. P.* The brown blotches on the leaves are caused by the mining larvae of a small moth, possibly *Lithocolletis messaniella*.

PIGEON MANURE: *Reader.* See reply to *Single-handed* under Vines.

RHUBARB: *Sherwood.* The variety Paragon, though with stems less highly-coloured than in some Rhubarb, is one of the most productive and best in cultivation; the quality is excellent, whilst the plant seldom if ever runs to seed.

SOIL FOR EXAMINATION: *B. and Sons.* The sample of soil has been subjected to a critical examination, with the result that no trace of eggs of any kind of insect were found. Instruct your correspondent to collect examples of the "eggs" to which he refers and forward them carefully packed without earth.

TULIP: *J. McK.* The short flower-stalk is the direct outcome of an insufficient depth of plunging material and a too early exposure to light. Judging from the example before us, the plants have hardly been covered with soil, and this with early exposure to light and greenhouse warmth has brought about the result of which you complain. In the garden plants are set a few inches deep, and in forcing this principle should be followed. All bulbous-rooted plants should be first prepared for forcing by plunging the pots, and when the shoots have started they should be grown in darkness in the forcing department to obtain a maximum stem growth.

VIOLET PRINCESS OF WALES: *C. C. G.* The variegation in the blooms is apparently due to some mechanical injury. However, it may be worth while to cultivate the plant for another season to see if the variegation is constant. If so, you might submit specimens to the Floral Committee of the Royal Horticultural Society at one of the R.H.S. fortnightly meetings with a view to seeing whether or not the variegation is regarded as a desirable quality.

THE ROCK GARDEN AT WISLEY.

(See Figs. 102, 103, and Supplementary Illustration.)

A SHORT account of the Wisley Rock Garden may prove useful to any who are contemplating the construction on a large scale of a home for Alpines and other plants that are the better for one or other of the advantages derived from the variations of aspect, slope, and drainage provided by a rock garden.

Also, although the promising infant has not yet attained to the zenith of its fame and glory, beauty and strength, it is as well to record the actual facts of its parentage, birth, and education, while they are fresh in mind. It is possible to commence with the conventional biographical opening and say it was born of poor but honest parents, for its immediate predecessor, that which bore the title of the rock garden at Wisley, exemplified both adjectives. From that poverty sprang the desire for something better, and so the project was born.

The obviously suitable site on the sloping bank that descends from the hill top

to the picturesque old ponds was chosen. Tenders for designs were invited and the Sub-Committee appointed by the Council to examine and advise upon those plans may be likened to the infant's godparents, and their selection of that prepared by Messrs. Pulham and Mr. Edward White decided the general lines of its future and named this child. So a rock garden of terraced slopes with a central watercourse forming a pool or two in its winding descent, to be carried out in Crowborough stone, was commenced in January, 1911. The Crowborough stone was selected as the most suitable to be found within reasonable distance that would provide large masses of a warm, yellow-brown colouring calculated to harmonise with the sandy soil of the garden.

The effects produced by some of the largest unbroken blocks have proved the wisdom of this choice, and when more of the smaller ones are partially covered by neighbouring plants, and shrubby plants have grown into rounded mature specimens, the somewhat regular and rectangular cleavage of this stone will not be sufficiently exposed to be monotonous. The quarries are about forty miles distant from the garden, and the blocks were brought by train to Horsley, one of the nearest stations, four miles away, so the carting was a serious matter, considering that over five hundred and fifty tons of stone were required for the work. The area covered is, roughly speaking, a hundred and one yards by ninety, that is to say, nearly two acres, and though by its natural slope splendidly fitted for a rock garden, the absence of a sufficient water supply at the top, and the nature of the soil, added two great difficulties.

It was decided to build a large tank on the top of the hill and to pump water up to it from a well three hundred and fifty yards away, and seventy-five yards below it, and this having been done there is now an ample and most satisfactory water supply available for watering purposes and for filling the streams and ponds. The tank has a capacity of twelve thousand gallons, and the well promises an unfailling supply.

By the middle of August, 1911, the actual construction of the rocky portion was pronounced finished, and the preparation of special soils for various aspects and the needs of different classes of plants was commenced.

A series of moraine beds was planned close to the stream, so that underground pipes might be laid to convey water to each bed separately. These sunken pipes, with holes bored in them at intervals of three inches, are laid about eight inches below the surface. They have been found to work well and to keep the beds moist without wetting the leaves and collars of the plants, and many rare and interesting Alpines are thriving in them, such as *Campanula Cenisia*, *Wahlenbergias*, and *Androsaces*.

The total cost of the rock garden, including the water supply and purchase of plants, amounted to £1,350. More than two thousand plants have been bought, besides something like fifty-five

thousand which were raised in the gardens for the purpose of furnishing it, and about twelve hundred have been presented by Fellows of the Society, so that by means of propagation and division of many of the plants, the rock garden now holds about sixty-five thousand. Nevertheless, it is still far from full, a fact which has called forth a certain amount of criticism, but to those endowed with patience and a knowledge of large rock gardens it will be clear that this is by no means a misfortune.

Undue haste to see the spaces filled is apt to lead to the planting of showy, rapidly-spreading things that exhaust the fresh soil so much that when they are cleared away to make room for worthier plants, it is hard to get the newcomers to thrive, and nothing produces so natural and beautiful an effect in the end as allowing ample room for plants to spread out in their own way into large specimens, rather than the filling of a space with a large number of small ones.

Certain plants, especially those that do not mind the absence of lime, are thriving amazingly, but the fine sand, and in parts an underlying, sour, bluish clay, need much careful mixing with leaf-soil and mortar rubble to produce a suitable rooting medium for what in many gardens are the most easily grown plants.

The encrusted Saxifrages, and even many of the mossy section, look very unhappy in some crevices that appear well adapted for them, while *Ramondias*, *Haberleas*, *Soldanellas*, and many *Primulas*, including *P. Winteri* and *P. Allionii*, look the picture of health.

A little colony of good forms of *Saxifraga Bursariana* on a ledge was, when I was last at Wisley, as fine as any I have seen in the open air, but forms of *S. Cotyledon* and *S. Aizoon*, that will thrive in most places in spite of any amount of neglect, are yellow and sorry-looking although in good positions. On the other hand, *Parochetus communis* was one of the happiest-looking plants in almost any position last summer. Stores of suitable materials for the improvement of the soil whenever it is unsatisfactory have been provided, and it is hoped that when this has been done the beds and ledges that settle down too much, or become close and sour, and fit to grow nothing but *Marchantia*, may be rendered open and friable, and suitable for good plants.

A useful range of frames has been arranged above the tank, close by the Alpine House, where new and delicate plants may be nursed into vigour before they are planted out, and these frames are filled with sand, so that small pots may be sunk in it, and this has been found very successful in helping to establish and recuperate many a sickly or freshly collected rarity. The photographs reproduced herewith give a good idea of the general appearance of the Rock Garden last summer, and I trust also foreshadow what a year or two more of careful attention and further planting will produce in the way of a beautiful picture, as well as an interesting and rich collection of Alpine and Rock plants. *E. A. Bowles.*

ORCHID NOTES AND CLEANINGS.

THE BRACKENHURST COLLECTION.

BRACKENHURST, Pembury, with its charming residence and large garden and woodland, was purchased by Mr. J. Gurney Fowler partly because the locality was known to be highly favourable for the cultivation of Orchids. The place is situated on high ground a few miles out of Tonbridge, and there Mr. Gurney Fowler has prepared a model block of houses to which he has removed his Orchid collection, which had for many years been famous as the Glebelands collection.

Under the guidance of Mr. Fowler we were privileged to make an inspection of the new

Electric light is installed everywhere in the Orchid houses and buildings, and before next winter the Rose-covered walk from the house to the Orchid quarters, and some other parts of the garden, will also be supplied with electric light for use on evening visits. Important points leading to success in Orchid culture, such as the heating, ventilation, and the arrangement of ample storage for water, have in the Brackenhurst houses received due attention. There is great power in the boilers, and an ample supply of hot-water piping, kept as low as possible in the base of the houses and well provided with check-valves, so that every section can be regulated as required.

In the basement of the houses the natural earth provides the surface in all the parts pos-

admitting of a free circulation of air on all sides of the plants, and generally it is evident that well-studied accommodation has been provided with the best results.

The back wall of the corridor, against which is suspended a fine collection of Dendrobiums, which plants are now covering its entire length with a charming display of finely-coloured, fragrant blooms, gives the greatest display of the season. Dendrobiums, like other classes of Orchids, fluctuate in point of favour with Orchid-growers, but there is no doubt that for a show of spring flowers nothing can compete with them. The compact plants at Brackenhurst have the pseudo-bulbs densely set with flowers varying from white to rose, purple and yellow in all shades, and forming literally a wall of bloom. Varieties

houses. The plants were in the most satisfactory condition and appeared to be enjoying the change they have got by their removal from Essex to Kent. The six houses, with orchard house for fruit trees in pots, are connected by a lean-to corridor, at the back of which is a north house for Cymbidiums, Masdevallias, cool Oncidiums, etc. Here, too, are the two large Robin Hood sectional boilers which heat the whole block, the bothies for the gardeners, fitted with bathrooms and every appliance useful for the comfort of the men, the large potting-shed and storage for potting materials, and at one end the office of Mr. J. Davis, the gardener, and which has telephonic communication with the house and the exchange.

sible, and the rocky sub-soil and porous nature of the top soil in this locality render this arrangement of great value to the plants.

The staging provides for the automatic distribution of moisture in the atmosphere, the evaporation from the arched brickwork on which the staging is arranged being regulated by the hot-water piping beneath, and by the general temperature of the house. The lower close staging on a level with the top of the arched brickwork has angle-iron frames, on which are placed ordinary porous red tiles to form a moisture-giving surface. This is not covered with shingle or any other material, as the tiles alone are found to answer all purposes. The open-woodwork upper staging is well elevated above the lower one,

of *Dendrobium nobile* are there, some of the old favourites, like the true *D. nobile nobiliss* with its profusion of rich-coloured flowers, being still unrivalled. So also the pure white *D. nobile virginale* among whites, *D. rubens grandiflorum* and the varieties of *D. Apollo* still merit their place. Among yellow forms *D. Thwaitesiae* and *D. Chessingtonense* were in great beauty, and some new hybrids of them and of *D. signatum* were very distinct and pretty. Several had fine canary-yellow flowers with maroon blotch in the centre; *D. signatum* × *Alice Bound* produced a pretty form with primrose flowers, and the same crossed with *Ainsworthii*, gave a large-flowered kind with yellow flowers having no blotch on the lip. Several pretty forms resulting from fertili-

sation between *D. nobile Amesiae* and *D. n. virginale* were interesting. No white like *virginale* results; some are almost identical with *Amesiae*, and others have the violet blotch on the lip larger and darker than in *Amesiae*, although a colourless form was used in obtaining the plants. Some seedlings of *D. Cybele* × *nobile nobilius*, *D. Sibil* and others, were also in bloom, and several *D. Hookerianum* and other showy *Dendrobiums* were making up their flowering growths.

In the corridor, suspended overhead, are a very fine lot of *Laelia anceps*, chiefly the best white forms; *L. Gouldiana*, and a number of the yellow *Cattleya citrina*. In the north house, in bloom, were *Cymbidium glebelandense* with two spikes of 4 to 5 feet, each with numerous flowers;

shaped flower with deep rose-red sepals and petals, with the yellow ground showing between the blotches, and with rose-tinted tips, the pandurate lip being rose-coloured in front, and with a purple band and some dark spotting around the yellow crest. The Brackenhurst variety of *Odontioda Madeline* (*Charlesworthii* × *crispum roseum*) was also in bloom, its richly-coloured petals having a thin yellow line inside the margin; and a promising *Odontioda* raised by Messrs. Charlesworth between *Odontioda Bohnhoffiae* and *O. Harryanum*, had nearly black buds and was being watched with interest. A good collection of hybrids of *Odontoglossum Rossii rubescens*, including the stock of the original *O. Smithii*, was also thriving here.

The next house contained a fine collection of

suspended some young plants of new *Laelio-Cattleyas*. The end division is the seedling house fitted with seed-raising case, in which were promising crosses in the first stage. The lens reveals the success likely to be attained, and the wisdom of the arrangement of the warm case in a uniformly warm, moist house. On an elevated staging were nice batches of *Sophronitis* crosses of promising parentages, both primary and secondary crosses of *Sophronitis grandiflora*. They are sturdy little plants and should soon develop into the flowering size. The next house had a wonderful collection of unflowered hybrids of *Cattleya*, *Laelia* and *Brassavola*, to flower within the next three years, at the end being a screen of *Vanda teres* with some *V. Miss Joaquim*, and two healthy plants of *V. Hookeriana*.

FIG. 103.—CASCADE IN THE WISLEY ROCK GARDEN.

(See p. 229.)

(Photograph by J. Russell & Sons.)

four plants of *C. J. Gurney Fowler*, of unknown parentage, each with several spikes of cream-white flowers, having a zone of red spots on the lip. The spikes are perfectly erect, and the flowers indicate *C. eburneum* on the one side. *C. Woodhamsianum* Fowler's variety (F.C.C., 1912), the finest *Cymbidium* of its class, was noticed, and some *Masdevallias* were also in bloom and bud.

In the main block, the first house contained a fine selection of the newer hybrid *Odontoglossums* and *Odontiodas*, some of the crosses not having yet been flowered.

Odontioda Brackenhurst (*Odontioda Charlesworthii* × *Odontoglossum eximium*), a great beauty flowering for the first time, is a finely-

Cypripediums, with *Miltonia vexillaria* suspended overhead. The famous *Cypripedium Leeaunum* J. Gurney Fowler has been increased, and it is being tried in the warm and cool *Cypripedium* houses to see in which it thrives the better, for although a sturdy grower it does not make growths rapidly. A finely-coloured form of *C. Miss Louisa Fowler* showed that it is still a very worthy and distinct *Cypripedium*; other notabilities were a brightly-coloured *C. Dicksonianum*, *C. chrysotoxum*, *C. Memaria Jeringhamiae*; a showy set of varieties of *C. aureum* and others. The third range contained the warmer *Cypripediums*, including the crosses of *C. bellatulum*, *C. niveum*, etc., some of which were in bloom, and overhead were

The large *Cattleya* house contained at the end a display of bloom made by a very handsome *Laelio-Cattleya* George Woodhams; some other *Laelio-Cattleyas*; two fine white *Cattleya Susanne Hye de Crom*, several good *C. Trianae*, *C. Schroderae*, *Brasso-Cattleya Cliftonii*, with very large white flowers, already set for seed; *Calopha Scripta*, and others. Famous plants noted were *Brasso-Cattleya Dighyano-Schroderae* Fowler's variety, with two buds; *Cattleya Schroderae Glebelands* variety, and others for which awards at the Royal Horticultural Society have been obtained. At the end are some *Sobralias* flowering well, and *Chysis bractescens*.

The large *Odontoglossum* house, which was such a success at Glebelands, was brought to

Brackenhurst and reconstructed. The famous collection of *Odontoglossums* and *Odontiodas*, always in fine condition despite their former residence in the Metropolitan area, are now exhibiting extraordinary vigour, even the smallest plants showing flower-spikes, some two from a bulb, efforts which are checked by pinching out most of the spikes this year to admit of the plants getting full benefit of the change.

The many choice varieties of the Glebelands collection are of absorbing interest. *Odontoglossum Aquitania*, said to be the best *Odontoglossum* yet seen, size, shape and colour considered, is in fine health; so also are *O. illustre Europa* (F.C.C., June 20, 1911), *O. Jasper Fowler's* variety, *O. crispum Saga*, *O. Arnoldianum*, *O. Halseyanum*, and other of Mr. Gurney Fowler's Certificated plants, all of which have been successfully grown, and some increased by division. With such a large number of rare plants, and a steadily

out-of-doors, a very different treatment to that usually given to *Ageratums*. It is usual to sow them in heat in February or early March, and grow on for bedding out in May, or they are propagated from cuttings taken from old plants wintered in pots in the greenhouse. This question of height may be largely due to locality and climate. In Kent and Essex I can quite believe annuals will generally be dwarfer than in the north; in fact, I know that many of them are. *Blue Perfection* was deeper in colour than *Little Dorrit*, and had larger flower heads. The colour is best described as lavender-blue. The plants bloomed continuously till frost came. This is doubtless caused by the fact that they set no seed. One of the most charming effects I ever saw on a large scale with two annuals was a huge bed of *Mignonette*—perhaps 200 feet long by 8 or 9 wide—recessed into the front of which, in great crescent-shaped masses, was a fine strain of *Ageratum*.

FIG. 104.—*CHRYSANTHEMUM INODORUM* "BRIDAL ROBE": FLOWERS WHITE.

increasing number of hybrids, Mr. Davis and his staff must be always busy; but the good accommodation provided insures the best results for their labours.

The study of Orchid hybrids, so elaborately and accurately recorded in his stud book by Mr. J. Gurney Fowler, gives that gentleman a vast amount of pleasure, and forms his chief recreation.

ANNUALS.—IV.

KEEPING to my idea of talking about annuals according to their heights, I have in view now species which grow about 1 foot high.

AGERATUMS.

The dwarf forms are selections from *A. mexicanum*, which, introduced into this country in 1822, grows from 18 inches to 2 feet in height. *Blue Perfection*, *Little Dorrit* and *Little Dorrit White* are stated in catalogues to grow from 6 to 9 inches. They grew 11 and 12 inches with me, and it must be remembered they were sown

ARCTOTIS.

I refer to *Arctotis* here because the plants do not run to more than about 10 or 12 inches in height, though the slender flower-stalks rise to twice that height. *A. breviscapa* is very showy. The blossoms are rich orange-yellow, Daisy-like in form, with dark centres. Each petal has a glossy-black mark at the base, and the expanded flowers are 3 inches in diameter. *A. grandis* is much taller—28 inches to the top of the flower. Its colour is palest lilac on the outside, white inside, with pale blue centre.

BROWALLIA.

Browallia elata produced fine, compact plants 12 inches in height. The glossy, green foliage was well covered in fine weather with very pretty blue flowers, about $\frac{3}{4}$ inch in diameter, with white centres. One frequently sees this and its white counterpart treated as greenhouse annuals, and they are very effective as such. The *Browallias* belong to the Solanaceae (Nightshade) Order.

CAMPANULA LOREYI.

This is truly a beautiful annual *Campanula*. Its height is 12 inches. For a long period it was smothered in bloom, each blossom being about $1\frac{1}{2}$ inch in diameter. Two varieties were grown, one having mauve-blue, the other pure white flowers.

CENTRANTHUS.

Centranthus macrosiphon or the annual *Valerian* grows about 12 inches tall, and produces large heads of deep rose-coloured flowers. It is an easily-grown annual, and, if well thinned, its fine foliage is seen to advantage.

CHRYSANTHEMUM INODORUM BRIDAL ROBE.

(See fig. 104.)

This is a dwarf (12 inches) form of *inodorum* producing in great abundance pure white, double flowers. It is a recent introduction, and for bedding purposes will be found most valuable, as it grows easily and remains a very long time in bloom.

DELPHINIUM BLUE BUTTERFLY.

This is an introduction of Messrs. Carters. I doubt if it is a true annual, as I have often seen plants stand over winter; nevertheless, treated as an annual, it is most valuable, giving a clear note of effective blue in the border. The plant grows from 12 to 14 inches in height. It branches well, and continues to flower for nearly three months.

NEMESIA.

Previous to the introduction of *N. strumosa Suttonii* by Messrs. Sutton, one could not say that the *Nemesias* were popular, but now they are decidedly so, and they grow remarkably well in northern counties. Much work has been done in selecting and improving during the last few years, and now many of the flowers are over an inch in diameter, and of the most beautiful shades of colour—rich orange, rich crimson, every shade of rose, and many primrose, ivory and white forms give an added charm. The seed is delicate-looking but germinates easily, even out-of-doors, but for an early display plants must be raised under glass, and planted out 6 to 9 inches apart. Recently some small-flowered varieties have been introduced; two of them—*Myosotis* blue and pure white—are very effective as bedding plants.

NASTURTIUM.

In this section of annuals there fall many of the most popular and largely grown, e.g., *Nasturtiums*, but everyone knows them, and there is nothing new to say about them. All kinds of *Nasturtiums* have a great vogue in the United States, the merchants handling tons of seed of them. Specialisation has developed a race of variegated-leaved forms, but these have never become popular here.

MIGNONETTE.

Mignonette also comes into this section. I often hear it said that *Mignonette* does not succeed in certain gardens. The following plan ought to be tried. Fill a dozen or two dozen small pots with a good compost, plunge in a shaded greenhouse, sow three or four seeds in the centre of each pot. When the plants are large enough thin out to one, harden off, and plant out in May, a foot apart, without breaking the balls of soil, and a grand result will be obtained.

A few notes on *Mignonettes* may be useful.

Golden Gem, 12 inches, deep golden, small heads of bloom, compact habit.

Crimson Giant, 12 inches, rather small flower-heads, red anthers.

Golden Queen, 15 inches, erect habit, golden-brown effect caused by golden-brown stamens being very pronounced. This is a remarkably good *Mignonette*.

Golden Machet, 16 inches, rather small heads, flowers greenish-white, stamens yellow.

Dobbie's Giant, 15 inches, large heads, bold habit, foliage like *Spinach*, greenish-white flowers with brown stamens.

Large Flowering.—This is the common Mignonette generally sold in cheap packets, 15 inches, small heads, greenish-white flowers, brown stamens.

Miles' Spiral, 16 inches, rather straggly growths, white flowers, with brown stamens. *W. Cuthbertson.*

THE MARKET FRUIT GARDEN.

A MONTH ago the rainfall of February was described as the greatest but one for that month at my station in fifteen years. For March the comparison is the same in character. The total measurement was 5.07 inches, taken on 24 days, and the only March in the preceding fourteen years approaching that quantity was that month in 1905, which yielded 5.14 inches. The average for fourteen years up to 1913 is 2.25 inches, and for a longer period it would be less, because we have had more rain in March than usual in six out of the fourteen seasons. The average number of rain days is 14.50. This year the number was nearly double, without counting two days in which there was a sprinkle, not measurable because not amounting to one-hundredth of an inch. So we had only 5 days of twenty-four hours entirely free from rain. My district is reckoned to belong to the south-east by the meteorological authorities, and no other division of England except the south-west had quite so much rain, though all had more than average in the first three weeks of the month, and two or three more than double the average. The complete official details for March are not available at the time of writing.

ANOTHER FUNGUS DISEASE SEASON FEARED.

There is grave reason to fear that the extremely wet weather of February and March will lead to the development of bad attacks of fungous diseases, like those of 1913. I do not know whether silver leaf is encouraged by wet weather or not, but canker in Apples and brown rot in Plums, Cherries and Apples certainly are.

OTHER DISADVANTAGES.

Never before have my workmen lost so much time in two months as they have lost in February and March by the frequent wet days or half-days. They are paid "wet or dry," but there has not been anything profitable for them to do when rain was falling. Some of the orchards are becoming grassy, and not a stroke with the hoe has been practicable up to the present. When the weather becomes suitable for the work there will be so much to do that it will be impossible to get it done quickly enough without employing many extra hands, and the supply is not likely to be equal to the demand.

STAGES OF VEGETATION.

Remarkably mild though the temperature of the last two months has been vegetation is not at all extra forward, probably owing to the coldness of the water-logged soil. Last season was such an exceptionally forward one that it is not a good one for comparison. To take the case of the earliest-blooming fruit, the Almond. It was in full blossom in the south of England in the last week of January, 1913. This year it was full on March 26, which is about a medium date. Early Pears showed clusters of blossom-buds last year on March 15, but were only just beginning to emerge from their sheaths a fortnight later this season. This is not much later than usual. Plums fortunately are not nearly so forward as they were a year ago, when my Black Diamonds were in full blossom on March 21, and Monarchs on the 31st. In 1912 the dates were March 24 and 30. This season at the end of March there were no signs of blossom, the earliest buds having only just begun to burst. Looking back to the records of many past years, I notice that April 20 to 25 has been usually the time for early-blooming Plums to be in full blossom. Apparently there will be a remarkable approach to contemporaneous blossoming among the differ-

ent varieties this season, as Black Diamond, President and Rivers's Prolific are very nearly abreast in bud-bursting, while the buds of Czar and Pond's Seedling were on the point of bursting at the end of March, and Victoria was very little behind them. Monarch, on the other hand, though usually only second to Black Diamond in blossoming, is no forwarder than Victoria at present in my oldest orchard. Perhaps this is because the trees are unhealthy from repeated attacks of brown rot, to which Monarch seems to be particularly liable. Many varieties of Apples showed clusters of blossom-buds last year on March 22, when a few blossoms were expanded on Irish Peach. This season the fruit-buds were only just bursting at the end of the month. My earliest date for Apples in full blossom is April 14, in 1906 and 1913; but the date was only one day later in 1903. In half my past fourteen seasons here Irish Peach or Bismarck has been in full blossom before the end of April. It may be so this year. Gooseberries were about half out in leaf at the end of March, as compared with March 15 in 1912 and 1913, both early seasons. Red Currants are nearly as forward as they were last year and in 1912, showing blossom-buds at the end of March, and Black Currants are quite as forward—namely, about a quarter out in leaf. Raspberry leaf was about as forward at the end of the month as it was a year ago on March 15.

THE PROMISE OF BLOSSOM.

There is a good all-round promise of blossom on Apples, Pears, and Plums. It is too early at the time of writing to say how Gooseberries and Currants will show in this respect, but the bushes are in vigorous condition. Black Currants, which rejoice in rainy weather, are particularly flourishing, and have made much growth in the last twelve months. A full display of blossom, however, is no guarantee of abundance of fruit, as was seen last season with Pears, Plums, and some varieties of Apples. Cox's Orange is thickly studded with fruit-buds, in spite of the removal of a great number of cankered spurs from comparatively young trees. An older lot has nearly recovered from an attack of canker. All Plums except Monarch have a great show, and nearly all Pears. As Cobnuts had an off season last year, and no severe frost has occurred since the female blossoms came out, while catkins are superabundant, there is good reason to hope for at least a fair crop.

USEFUL RESEARCH WORK.

It is greatly to be desired that entomologists engaged in research work should direct their attention to aphid attack. Let them search for eggs or mother queens on Apple and Plum trees and ascertain whether there are at present any signs of a forthcoming infestation. In pruning many hundreds of trees of both fruits I have noticed only one shoot of an Apple covered with aphid eggs, and I have not seen a mother queen or any eggs on a Plum tree. Yet it is to be expected that, as usual, there will be bad attacks on both these fruits, and the question is, Whence do the attacks come? The theory is that eggs are deposited upon the trees in the autumn, hatch in the spring, and produce viviparous insects. But if no eggs can be found now, and attacks should occur hereafter, the theory will be discredited—at least in part. In my opinion the life-history of the aphid is not known, at least so far as the location of the pest during the winter is concerned. Why should we assume that the eggs are on the trees if we cannot find any? Take the similar case of an attack of the aphid on spring-sown Beans. There are no plants in the winter to harbour the eggs, yet the tops may be densely covered with aphids when the crop has grown to nearly its full height.

In the course of the last two or three days of March I searched with a lens among all the varieties of Plums in one orchard, inspecting the

crotches of branches and spurs and last year's shoots. Multitudes of red-spider eggs were found, but not a single aphid or aphid egg. Several trees of each variety were examined. Yet I have no doubt that there will be the usual attack of aphid as soon as the leaves begin to show, as there has been in every preceding season. Similarly some varieties of Apples, usually badly infested with aphid, have been examined. Swarms of red-spider eggs were found, with sucker-eggs here and there, but not one aphid egg. Where are the eggs that will produce the infestation confidently anticipated? That is the question upon which research is needed.

LIME WASHED OFF TREES.

Even the latest-sprayed of my Apple trees have now had nearly all the lime washed off them, although in the latter part of the time the proportion of lime used was 1½ cwt. to 100 gallons of water. There was no difficulty in getting wash as thick as this large proportion of lime made it through the nozzles, to be distributed by the spreaders, to which reference was made a month ago. Trees sprayed with lime-sulphur still show the purple tinge which that wash imparts to them.

TOO MUCH FORBEARANCE.

Experience has convinced me that too much forbearance is commonly shown to fruit trees which make a bad start in growth or health. Many commercial growers give a short shrift to such trees. They cut them back and regraft them with another variety if the trunks and branches are sound. They are wise in their action. Unsound trees, of course, should be grubbed up, to give place to fresh ones. Trees are so cheap now that there should not be any hesitation in removing those which are not good enough for top-grafting, and substituting others of a variety proved to flourish in the district. There is much loss in leaving unprofitable trees to grow worse and worse, instead of dealing with them at an early period of their deterioration. *A Southern Grower.*

CULTURAL NOTE.

WINTER-FLOWERING STOCKS.

WINTER-FLOWERING Stocks are well adapted for pot culture, and come in most usefully for conservatory and house decoration during winter and early spring. The plants last well in flower, and the blooms are very sweetly scented. By sowing seeds in July they will start flowering in January. It is well to make a second sowing in August, to prolong the season of flowering. When the seedlings are strong enough to handle, prick them off into boxes, and grow them in a light frame; shade them for the first day or two, and afterwards admit plenty of air. In about three weeks or a month they will be ready for potting single into 4½ inch pots in a mixture of three parts loam, one part manure from an old Mushroom bed, one part wood ashes and lime rubble, and a good sprinkling of bone meal, and some soot. After they are potted stand them in a frame and shade for a day or two till they recover from the check of potting. Afterwards only use the lights to keep off rain. About the beginning of October they should be removed to shelves in vineries or Peach houses, close to the roof-glass, where they can get plenty of air. As they begin to throw up the flowers a little artificial manure will help them, Clay's manure and soot water being the two best. The best varieties to grow are Beauty of Nice (mauve and salmon-pink), Riviera Market (white and rose), and All the Year Round. I have tried other varieties, but find the above-mentioned to be the best, and have had from 70 to 80 per cent. double flowers. *Alexander Reid, Cheswardine Hall Gardens, Market Drayton.*

[Our correspondent sent with the above note some very finely grown specimens.—Eds.]

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

DECIDUOUS CALANTHES.—Plants that were treated as advised on page 38 are producing new growths. Many of those laid in boxes have rooted into the Sphagnum-moss and leaf-mould, and, the roots being very easily injured, great care must be taken in re-potting them. It is well to remove the old compost adhering to the roots. The proper stage at which to pot is directly fresh roots develop from the bases of the growing stems, for there will be less danger of injuring the roots than when they are further advanced. Specimens that have been rested in their pots should be turned out of the receptacles, and the old potting compost removed. In this case also exercise extreme care not to damage any young roots which may be present. The old roots should be cut away, leaving only a sufficient length to enable the pseudo-bulbs to be secured in position after they are re-potted. Few cultivators agree on which is the best kind of compost to use; much depends on where the garden is situated and the conditions under which the plants are cultivated. If the conditions are favourable to the requirements of Calanthes, the potting compost is only a secondary consideration. I refer to such species and varieties as *C. vestita*, *C. Veitchii*, *C. Bryan*, *C. W. Murray*, and those of the Regnier group, for all these have a vigorous constitution. It will also generally be observed that these Calanthes are mostly satisfactory in places where few other Orchids are cultivated. In most localities a mixture of fibrous loam, peat and Sphagnum-moss, with dried cow-manure, charcoal, sand, etc., added, constitutes the most suitable rooting medium. In certain districts the use of loam to any large extent favours the development of "black spot" in the very early stages of growth, and in such places compost of a light, quick-drying nature is the most satisfactory. In this neighbourhood some of the best-grown plants are planted in a mixture of peat, Sphagnum-moss, and leaf-mould, with plenty of charcoal and sand added to render the compost porous. When liquid manure is afforded in the later stages of growth this compost answers well. But no hard and fast rule can be laid down, and cultivators should test the different methods, for only in this way will they determine the best system to adopt for their particular district. The pots should be cleaned and filled to one-half their depth with clean, broken crocks. The sizes of the pots will be determined by the sizes of plants. Make the compost firm, and allow sufficient space at the top for watering. Moisture should be afforded sparingly during the first few weeks following root disturbance. Grow the plants in plenty of light, but not so intense as to cause scorching. *C. atro-rubens*, *C. Clive*, *C. Norman*, *C. Oakwood Ruby*, *C. Chapmanii*, and *C. Angela*, the finest of all the dark varieties, all do best in a light compost, very similar to that used for *Odontoglossums*, using no loam whatever. Most of these varieties are scarce and not in general cultivation, but as they become more generally known their merits will be appreciated.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

PROTECTION.—It is always advisable to afford a little shelter from cold winds and strong sunshine to plants that have been raised under glass, for they are sure to be a little tender. The protection may consist of a few short sprays of Yew, Spruce, or other common evergreens stuck in the ground on the windward side of them.

GALTONIA CANDICANS.—This plant, often known in gardens as *Hvacinthus*, may be planted with safety now. We find it very suitable for mingling with groups of herbaceous

Paeonies in open spaces in shrubberies, where they produce a charming effect in the late summer when the Paeonies are over. The stately spikes show to advantage against the bronze foliage of the Paeonies and the greenery of the shrubs at the back.

GLADIOLI.—These bulbous plants may also be planted now, and it will be an advantage if the corms have been started in boxes, for this will hasten the flowering season. The varieties of *branchleyensis* are cheap, and if three or four hundred corms are associated with about one hundred plants of *Hydrangea paniculata* a gorgeous effect will be produced. Of named varieties *America*, *Faust*, *Baron J. Hulot*, *Hollandier*, *Prinsep*, *Pink Beauty*, with *Graaff's* and *Lemoine's* hybrids offer an excellent selection for planting in special beds in the bulb garden.

LILIUM.—Certain Lilies, such as *L. speciosum*, *L. tigrinum*, *L. auratum*, and *L. speciosum* var. *Melpomene*, may be planted as recommended for Gladioli, although some of the choicer varieties seem to do better when grown with a "foster" plant, such as *Iris* or *Sedge* grasses. Of late years mites have been very destructive to Lilies, and the pests have spread to our *Montbretias*.

PAMPAS GRASS.—Where it is desired to increase the stock of certain pure-white, plumed varieties the plants may be divided now. Each portion should consist of from one to six good crowns, and be replanted as advised for Bamboos. Seedlings may be raised under glass, but numbers of the plants will revert to the original dull-brown form. In dividing the old clumps plant any small pieces that become broken off in the reserve garden, when, after one season, they will make grand specimens.

GUNNERA MANICATA.—This fine ornamental-leaved plant is as easily cultivated as *Rhubarb*, but the crowns require a little protection during the winter. The protection may consist of a few Oak leaves held in position by evergreen branches. The plant is a gross feeder, requiring plenty of moisture and manure at the roots.

LAWNS.—The work of mowing lawns should be delayed no longer. We always employ scythes at the first cutting, for this levels up inequalities in the turf, and the hard sweeping that follows removes grit, stones, and other rubbish that would blunt or otherwise damage the lawn-mower. Where there are large, open areas of short grass to be kept, a mower driven by motor power will be found a great saving of labour. The makers have perfected these machines, which may be driven under perfect control, and travel fast in and around flower beds. Moreover, they do the work better, for they obviate treading on and disfiguring the verges of gravel paths.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

VINES.—Grapes that are beginning to colour require a free circulation of warm, dry air. Moisture should not, however, be withheld too suddenly, but by degrees, as the berries advance in the colouring process. The temperature in later houses, where the fruit is swelling, may be 75°, with a genial, moist atmosphere. Thin all bunches in succession vineries as soon as the berries are fit, the extent of the thinning depending, of course, entirely upon the state of the vines. Strong, healthy plants will swell their berries to double the size of others of the same kind growing under less favourable conditions, so that experience alone can teach the degree to which the bunches of fruit may be thinned. Attend to those vines that are in bloom as advised in a former issue, preventing sudden changes of temperature as much as possible. Disbud and stop at three buds beyond the bunch all growths on vines at a later stage. No time should be lost in starting late houses, syringing the rods both morning and afternoon, and closing the houses early to secure as much sun heat as possible, with a genial, moist atmosphere. Less trouble is usually experienced in the starting of late

vines than with early ones, but it is well to lower vigorous canes, so as to secure an equal or uniform bursting of the buds.

PEACHES AND NECTARINES.—Pot trees or specimens planted out in the borders with fruits in which the stoning process is completed, should be grown in a temperature of 75° or 80° by day, with an increase of 10° to 15° by sun heat. The night temperature may range from 65° to 70°. Maintain a moist atmosphere and afford a little top ventilation during nights when the weather is mild. The final thinning of the fruit may now be done, but in doubtful cases remove the superfluous crop by degrees. Keep all late houses well aired and as cool as possible. Syringing should be carried out with great care; an excess will destroy the tissues of the leaves and induce a sappy growth. The water should be ejected from the syringe with sufficient force to dislodge insect pests, but not so vigorously as to tear or damage the tender foliage.

THE ORCHARD HOUSE.—Now that most of the fruit is set syringe the trees gently on mild mornings and maintain a closer and moister atmosphere in the house in order to assist the young fruit to swell and the wood-buds to grow rapidly. Close the ventilators early in the afternoon and thus conserve the heat of the day for warding off the cold at night without using much fire heat. Syringe the plants freely on warm afternoons, but withhold syringing in cold, damp, or frosty weather, at which times a drier atmosphere is best. Carefully go over all the trees and pick off all decayed flowers and leaves. Disbud Peaches where necessary, removing only a few buds at first, as it is better to do this gradually than to remove a large quantity at one time, which may seriously affect the constitution of the tree. If green fly appears dust the plants with tobacco powder, but first spray the trees gently with clear water to make the powder adhere. If more convenient, light fumigations may be practised instead. Examine Apricots, Cherries and Plums for the presence of grubs and caterpillars, which will be found curled up amongst the young leaves and shoots. Constant supervision in this respect is necessary to keep these pests in check; the only means of doing so is to search for them by unfolding the leaves and destroying any grubs which are found. Afford the roots plenty of water at all times, for if they are allowed to become dry the fruits will be sure to drop.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOZE,
Eastwell Park, Kent.

PLANTING STRAWBERRIES.—Runners that were secured late last autumn and wintered in pots in cold frames or plunged in ashes should be planted in their permanent quarters as soon as the soil is in a suitable condition. The recent heavy rains have caused retentive soils to become very bad for working, but it is better to wait for a week or so than to trample the ground whilst it is wet. Strawberries repay for good cultivation, and, as the plants usually occupy the same site for two or three years, it is necessary to thoroughly trench and manure the ground previous to planting. When the soil has become settled, fork it over on a drying day, levelling the surface with a rake before making the drills for planting. A dressing of wood-ashes or old potting compost forked in the top spit will be beneficial in assisting the plants at the start. The materials should be worked around the roots when the planting is done. Strawberries succeed in a variety of soils if afforded good treatment, but for preference choose a cool, retentive loam for the main crop. Moderate numbers of plants of an early variety should be grown on a warm border, where they will fruit considerably in advance of those in the open quarters. Royal Sovereign is the most reliable variety for the purpose, but the newer King George is being recommended as a little earlier. The growth of Strawberries varies according to the quality of the ground, in rich soil a distance of 30 inches between the rows, and 24 to 30 inches between the plants should be allowed. When

planting from pots disentangle the roots carefully, spreading them out evenly, and keep the crown of the plant level with the surface. Make the soil firm about the roots, and run the flat hoe through the beds when the work of planting is finished. Young Strawberry plants put in now should not be allowed to crop this season, therefore all flower-spikes should be picked off as soon as they develop. If the ground is limited, small salad plants, such as Lettuces, Radishes and Onions, may be grown in the space between the rows for the first season. These supplementary crops will mature quickly, and will not harm the Strawberries. If drying winds prevail directly after the plants are put out spread a light mulch over the roots, but not heavy, rotted manure. For the latest crops a border on the cool side of a wall should be planted with Givon's Late Prolific, Latest of All, or Laxton's Latest.

ESTABLISHED BEDS.—If these were cleansed and mulched during frosty weather, as recommended in a previous calendar, very little need be done now. Assuming strawy litter is to be employed for keeping the fruits clean, let it be placed along the rows early, in order that it may be perfectly bleached and clean before the flower-spikes appear. There is a double advantage in placing the litter along the rows early in the season, for in times of frost, when the flowers are opening, the litter may be lightly shaken over the plants in the evening, and, unless the frost is exceptionally severe, will protect the blossom from injury. The plants should be uncovered from the litter next morning as soon as the temperature rises. Before putting the litter down give plants that have already borne heavy crops a light dressing of artificial manure, and also dust soot around the crowns. The soot will help to ward off slugs, which usually take a heavy toll of the fruits.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knutsley Hall, Lancashire.

CHRYSANTHEMUMS.—Pot the remainder of the plants rooted in January at once, using similar compost to that recommended on p. 109. Bush varieties may be placed two or three in each 4-inch pot. Press the soil moderately firm, stand the plants on an ash bottom close to the roof-glass, and keep the atmosphere close for a few days, shading the plants for a few hours about midday. Plants intended for furnishing large blooms should be potted into receptacles 5 inches and 6 inches in diameter before growth becomes stunted. Stand them close to the roof-glass. Stop the shoots of decorative varieties when about 4 inches to 5 inches long, and pinch the secondary shoots from these when they have grown about 5 inches. Syringe the foliage with quassia extract in preference to fumigating for the destruction of aphides. A batch of cuttings of outdoor varieties (Masse and Goacher types) may be struck now to furnish bloom for the conservatory in the autumn. Grow two plants in each 7-inch pot and pinch the shoots twice. The plants will bloom after those in the borders and before the earliest of the indoor varieties.

MARGUERITES may be repotted and placed in a cold pit. Dip the plants occasionally in petroleum emulsion to keep the fly that lays the leaf-mining grub in check.

BEGONIA GLOIRE DE LORRAINE.—A batch of this plant should be placed in a moist, warm house to produce cuttings for flowering next winter. In a temperature of 70° suitable shoots for cuttings will soon develop at the base of the plants, and these may be taken off and inserted when 2 or 3 inches long. Strike the cuttings in pans or pots furnished with plenty of drainage and filled with a mixture of equal parts loam, leaf-mould and sand. Water the soil with a fine-rose can; subsequent sprayings overhead will afford sufficient moisture until roots form. Place the receptacles on a stage close to the roof-glass and keep the cuttings shaded at all times, but the atmosphere must be kept in circulation.

HYBRID BEGONIAS.—The varieties *Ideala*, *Bowden Beauty*, *Elatior*, *Winter Cheer*, *Gloire de Sceaux*, and others, may be propagated in

the same manner as the above. The plants are very subject to infestations of mite, which should be destroyed by frequent fumigations and dipping the plants in quassia extract.

BEGONIA REX.—This ornamental-leaved plant is best propagated from leaf-cuttings. Select well-developed, fully-matured leaves, make incisions across the main nerves, and lay the leaves flat on a sand bed or a layer of coconut fibre. In moist, shaded conditions plantlets soon form, and may be potted up as soon as they can be handled.

IMANTOPHYLLUM (CLIVIA).—The plants are becoming active again after being rested, and some are pushing up their flower-spikes, therefore water may be afforded from now onward. Applications of weak soot-water and liquid manure diluted with clear water may be afforded the roots twice weekly, also a little Thomson's manure. Where Palms and similar plants are grown in beds in a conservatory a row of *Clivias* makes a suitable border, and established specimens thrive for many years with very little attention.

DECORATIVE GRASSES.—*Eualia*, *Carex*, *Isolepis gracilis*, and other ornamental grasses and sedges may be overhauled forthwith. The plants may be increased by dividing the old stools carefully; retain all the foliage of *Carex* and *Eualias* until new growth commences. *Isolepis* may be grown in 60-sized pots, and the other kinds in 4½ to 5 inch pots. Use a compost consisting of equal parts loam and leaf-mould with sand added. Members of the *Carex* family are benefited by a little peat in the soil. *Cyperus alternifolius* and *C. natalensis* may be raised from seed sown now.

THE KITCHEN GARDEN.

By R. P. BROGHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

HOEING.—Seedling weeds will soon make their appearance everywhere in the kitchen garden, earlier or later according to the locality and the nature of the soil. The cultivator should hoe very carefully the whole cropping ground as soon as the first weeds appear. In the case of crops which are growing in rows and above ground the system pursued by market growers is much to be preferred to that usually adopted in gardens—that is, the workman pushes the Dutch hoe in front of him, following it in the adjacent interspace. The work is equally well performed, if not better, than by the method of short strokes and moving backward, while there is a great saving in time. Potatoes can be safely surface-hoed for some time to come in the old, accustomed way.

SEAKALE.—The roots that have been protected should be examined at frequent intervals, and the heads cut as they become fit. These are much superior in flavour to those forced. If there was a shortage of "thongs" to plant, it is possible to pick out enough of the cropped roots to make up the deficiency. These should be planted at once.

POTATOS.—The soil has been so wet that planting has been delayed in many localities. No time should be lost in planting the whole of the crop, even if the old-fashioned, if condemned, practice of planting with a dibber has to be resorted to. Much will depend on the condition of the soil for this method to succeed, and as soon as possible subsequently the ground between the rows should be forked deeply.

BROCCOLI.—The first week of April is generally a suitable time in which to sow seeds of this important vegetable. Some incline to delay sowing for a time, believing that later plants, though smaller and less vigorous, are more capable of withstanding the winter than larger plants. My experience shows that a long season of growth is required to produce strong plants, which need not be more susceptible to intense cold than smaller specimens. Moreover, they have the advantage in providing heads of a good size during winter, which immature plants fail to do. It might be a question, too, in very cold districts, whether to continue growing the old-fashioned and hardier varieties, or instead

substitute the newer kinds, which partake so largely in growth and quality of the Cauliflower. I have found birds so destructive to seedlings, even when nets were used, that I now sow in rough wooden frames, which afford perfect protection when netted. The seeds are sown broadcast and thin enough to dispense with weaklings; by this system the seedlings need not be transplanted till they are well advanced in size. The following varieties may be strongly recommended: *Michaelmas White*, *Autumn Protecting*, *Superb Early White*, which produces Cauliflower-like heads throughout the later winter months; *Snow White*, of the same type but later; *Perfection*; *Safeguard Protecting*, ready about this period; *Satisfaction*, *Late Queen* and *Methven's June*, the two last-named meeting the early Cauliflowers. *Purple* and *White Sprouting* should not be omitted.

THE APIARY.

By CHLORIS.

SEASONABLE WORK.—When the weather becomes reasonably warm in April, the spring overhauling of the apiary may be undertaken. Remember this is the most important examination of the year, therefore do not start the work unless there is plenty of time to complete it thoroughly. Take note of the amount of food each hive contains, so that no further disturbance of the brood-chamber may be necessary. The record should be written on paper, for it is not wise to trust to memory. Then the quality of brood will be a good index to the value of the queen, always recollecting that an indifferent queen is valueless, and should be replaced. Weak stocks cannot be expected to yield much surplus honey, therefore two or more weak colonies should be united, performing the work about 4 p.m. Keep a watchful eye for the larvae of the wax moth, which are easily detected because of the silken web by which the grubs travel from comb to comb. A weak or neglected colony falls an easy prey to the wax moth, therefore because of this, if for no other reason, it pays to keep colonies strong. Sometimes it will be found possible to strengthen colonies by robbing extra strong ones of a frame of brood, or even one of sealed honey where a colony has plenty of stored food. In the latter case the cells should be bruised, and this will act as an incentive for the bees to feed. The floor-boards need attention. They should be cleansed thoroughly by scraping, in order to remove all adhering debris. The rubbish which collects on the floor decays and makes the hives insanitary, besides forming the breeding-place loved by the wax moth. There can be no doubt that many of the troubles among bees arise from the neglect of bee-keepers to keep their hives healthy and clean.

PURCHASING SWARMS.—It is only when bees are in a healthy state that they swarm, therefore swarms are the most satisfactory to purchase. Too often the beginner procrastinates until too late—i.e., until he actually requires the bees and swarming is in full swing. Then he finds that others have been in the field long before him, for they are placing their orders now, and remember the rule is, first come, first served. I shall be very much surprised if this season does not prove a very busy one for those who sell swarms, because the losses in most apiaries have been very numerous of late years, and there is a great demand for honey.

FITTING UP SECTIONS IN RACKS.—As this task takes up much time when properly done, it will be wise to do a little of the work now. By performing this task early the sections can be made to fit more tightly in the rack, for later every little crevice will be filled with propolis, thus causing more work in a busy part of the season, beside producing indifferent results, for there will always be a stain left in the white wood where propolis has been scraped off. Do not omit to utilise tin dividers between each line of sections to secure a uniform surface to each section. Tin dividers are preferable, because they are not liable to twist, as wooden ones do, and the bees are less likely to attach the sections to the metal.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C. — Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are mis-directed.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, APRIL 7—

Roy. Hort. Soc. Coms. meet. (Lecture at 3 p.m. on "The Cultivation of *Amaryllis*.") Hort. Club dinner and meeting; lecture by Mr. P. Amaury Talbot on "The Flora of Nigeria."

THURSDAY, APRIL, 9—

B.G.A. (London branch), meet. at Carr's Restaurant, Strand.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 46.1°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, April 1 (6 p.m.); Max. 66°; Min. 46°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, April 2 (10 a.m.); Bar. 29.5°, Temp. 56°. Weather—Fair.

PROVINCES, Wednesday, April 1. Max. 61°, Yarmouth; Min. 48°, Sheffield.

SALES FOR THE ENSUING WEEK.

MONDAY—

Hardy Bulbs, Herbaceous Plants and Roses. By Protheroe and Morris, at 67 and 68, Cheapside, at 12 noon.

MONDAY AND WEDNESDAY—

Rose Trees, Perennials, Lilies, etc. At Stevens's Rooms, 38, King Street, Covent Garden, 12.30.

WEDNESDAY—

Herbaceous Plants and Hardy Bulbs, at 12; Roses at 1.30; Palms and Plants at 5. By Protheroe and Morris.

Horticulture on the Riviera.

There are few green-grocers' shops in the country where at this time of year one may not see one or more of the flat reed baskets in which the produce of the Riviera coast is exported. The street flower-sellers, with cheap Roses up to the turn of the year, then with sprays of Acacia, Violets, and Anemones, draw from the Riviera to fill up the gap between the Chrysanthemums and the Daffodils; in fact, the cheap winter flower trade depends almost entirely upon French-grown produce. During a recent visit we had some opportunities of making acquaintance with this important industry, and found a little enquiry among those fine cultivators preferable to the indifferent golf, or even to the routine of pigeon-shooting, lawn tennis, and gambling that is so plentifully provided for the delectation of the English visitor. In the first place, it is a mistake to suppose that the Riviera industry in *primeurs* early vegetables and flowers, is in the hands of the peasant proprietors—the smallholders whom one usually associates with French gardening

and agriculture. The most important gardens are in the hands of men of education and capital, in many cases comparatively new comers, men who have taken up horticulture in the same way of business as a man in this country takes up bootmaking or law. There are, of course, in the district plenty of small proprietors who make a living out of the family acres they have inherited, but they are not the men who have developed the international trade in flowers and early vegetables, though they may do a little in that direction. The typical small farm will have a few acres of vines, interplanted as to some rows with Corn others with Beans, a few Olives, though they are being displaced by the vines, a few Orange, Peach, and Almond trees, and some carefully terraced beds for Globe Artichokes, early Peas, and the more easily grown vegetables and flowers. Further back in the hills most of the land will be uncultivated and occupied by Cork trees or Chestnuts, and in the valleys beyond the first group of hills the raising of silkworms becomes an important industry. In this easy climate the peasant's wants are few, and he is contented to farm easily for a comparatively small return in cash.

The intensive industry is carried on wherever a sufficient expanse of deep and level soil and an adequate water supply at a low elevation can be found. Sometimes there will be several square miles of such cultivation, as in the neighbourhood of Hyères, and in the broad inland valleys about Grasse and Draguignan, but wherever one of the mountain torrents from the Maures or the Esterel debouches on the coast there will be one or more enterprises of the kind, often working under the most favourable conditions as to shelter and aspect. The soil is generally a deep red loam, derived from the primitive rocks that border the coast line; it is full of stones and coarse sand, but is friable and easy to work. Chemically, it is very deficient in lime, and the climate keeps it short of humus. Natural manures are scarce, the cultivator keeps no live stock except the horses or oxen he uses for cultivation, there are few dairies or pigs in the district, so that farmyard manure is unprocurable, and the sea wrack that is thrown up on some of the shores possesses little manurial value, though it is occasionally used as a mulch. The cultivator has to depend chiefly on artificial fertilisers, among which cakes from the seed-crushing mills of Marseilles play a leading part. Many men have taken to the practice of growing a crop of Lupins whenever the land has to remain idle for a time, turning them in to renew the stock of nitrogen and humus.

The most important factor is water, and all the characteristic cropping depends on irrigation. The rainfall from the late autumn until May is abundant enough, but it is impossible to get summer crops or to establish such things as Broccoli, Endive, Violets, Stocks or Carnations for winter flowering without a plentiful supply of irrigation water, which may be

taken by a channel from one of the streams coming down from the hills or pumped up from a well. The practice of irrigation is well understood; the land is all graded into terraces, and the water is led from terrace to terrace along brick and cement culverts, which are cheaply and cleverly constructed by the local workmen. At the level of each terrace there is an outlet for the water closed by a tile sliding in grooves made in the wall of the culvert; when that terrace has to be watered the tile is lifted and slid into corresponding grooves across the culvert, thus diverting the flow of the water on to the terrace.

After water, elevation and aspect require consideration, and here there is a necessary conflict of interests between the high ground, where frosts are rare but water difficult to obtain, and the low ground, with deep soil and abundant water, but subject to frost. On the high ground a southern exposure is often obtainable, but the greater the slope the more expensive the terracing and the greater the consumption of water. Shelter is all-important. Some ideal situations are to be found close under the steep wooded hills which keep off the dreaded mistral, but there are no extensive areas of that kind, and as a rule men have to rely upon artificial wind-breaks. The gardens are often surrounded by tall belts of Cypress or Acacia, and the beds are all divided up by screens made from the ubiquitous reeds or the tall-growing native Heath. Thatches of the same Heath are erected about four feet from the ground over the beds of Violets and Anemones; Carnations are generally protected by reed mats, which are unrolled in the evening over a framework about two feet from the ground. Along every watercourse grow the reeds or cannae (*Arundo donax*) to a height of eighteen or twenty feet like rather stiff Bamboos, and they subserve a number of useful purposes—screens, blinds, mats, stakes, and other necessaries. The flat baskets which we see in all our markets, and in which all the flowers are despatched, are constructed from split reeds woven together by osiers, or nowadays more generally by wire, and it is wonderful what a tough and elastic basket can be thus cheaply constructed. To minimise the effects of frost it is not uncommon in still weather to light rubbish fires about dawn; the whole valley soon fills with smoke gently drifting seaward on the dying land breeze, to return again as the sun gathers strength and sets up a sea breeze.

The cheap vegetables grown are, in the winter, Broccoli and Endive, the broad-leaved having almost displaced the curled Endive; early Peas and Broad Beans are sown to come into flower in January in sheltered localities. Provence is also famous for its Globe Artichokes (the exhibits from Provence at the Chelsea International in 1912 will be remembered). Even in so backward a season as the present, small ones for making omelettes could be gathered in February. Nearly every garden possesses a considerable breadth of Globe Artichokes. As the season ad-

[Photograph by J. Russell and Sons.

ROCKERY IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS, WISLEY, SURREY.

vances Peas are sown in succession, and followed by French Beans, both haricots and flageolets, the most important crop of the year. Tomatoes are also planted out as soon as the danger of frost is past. Aubergines are less important, but Melons form a feature with many growers. A few men grow early Potatoes, but that crop does not constitute an important part of the farming.

Of the flowers the most important are the Violets, of which great acreages are to be seen about Hyères, magnificent clumps a foot across, and carrying a couple of hundred blooms. Nearly all are singles, La France, and some of the newer, large-flowered varieties like Admiral Avellan and Askania. Stocks are greatly in demand as cut flowers in France, and a good deal of space in the Riviera gardens is given up to the culture of a fine pyramidal variety, Quarantaine remontante, Giroflée de Nice, which comes to cut from Christmas onwards. They are followed by the Anemones and Ranunculus, but the greatest care and attention is given to Carnations. The Lyons varieties are most commonly grown, but the American perpetual-flowering are now gaining ground. They are not quite so full, and open a little better in seasons like the present, when there was much rain and cold. Sweet Peas are being tried, but the frosts in early January this year cut them to pieces just as they were flowering. All men grow a good many Marguerites (Anthemis), mostly white, with a few yellow; they can be cut all the year round, but chiefly in autumn, though as they can be grown on non-irrigated land they are not of much account. Roses are also very generally grown on non-irrigated land; they are pruned in the late summer, so as to flower when the autumn rains have started them into growth; in early spring they carry only occasional flowers of no market importance. Safrano, Marie van Houtte, Madame Abel Chatenay, and Richmond are the regular sorts. The Mimosa (Acacia), which in our markets is so closely associated with the Riviera, does not pay to grow; it has become the most frequent of hedgerow trees, until the traveller grows to detest its staring yellow colour and common aspect. About this time of year the hillsides on non-irrigated land under Olives are often beautiful with Freesia, Roman Hyacinths, and Paper-white Narcissus, which are being grown for the bulbs, not for flowers. The bulbs are sent from Holland for a year's ripening before sale. Lastly, one must not forget the Peaches, which are very generally planted along the irrigation terraces at such intervals as not to interfere with the crops below. Some of the Californian varieties are beginning to creep in because of their size and power of travelling. Marketing is mostly done through the agents of a few big firms who live in the district, and the usual thing is to fix a contract price for the whole of a man's production as it comes along. Some men try their luck with commission agents in Lyons, Paris, and other cities; others work up a private

trade with shops, hotels, and large houses. The railways give facilities for such a plan, as a box weighing 10 kilos. (22 lb.) is delivered at any station in France for 1s. 3d., and, of course, the tourist traffic maintains a very good train service, in addition to which the P.L.M. runs a special flower train to the northern markets.

Just as the owners of these properties are mostly settlers from other parts of France the workmen are equally strangers, and generally Italians from Piedmont. Of late the supply has been greatly reduced through the war in Tripoli, 4f. a day has to be paid for occasional men, 90f. a month to a man in regular employ, and the dearth of labour is only one of the changing factors that is rendering the Riviera flower-grower uneasy. Every year his monopoly is being threatened by other countries further south, particularly by Algeria, where men go who have been trained in his own school.

Even more insistent is the competition of the growers under glass; the rich people who pay the really big prices are taken by the finish, even by the comparative frailty of the forced Carnations, and do not trouble themselves about the superior lasting powers of the more naturally grown article. So glass-houses are going up on the Riviera just to get this last polish, and it will be interesting to see in a few years' time whether Mediterranean sunshine or northern coal wins the day. The South will certainly make a fight of it, for perhaps the most striking feature of this Provençal gardening is the high level of intelligence and education of the men engaged in it; it is a business for which men deliberately train themselves, first scientifically and then commercially, and in that respect it has a pull over the haphazard methods prevailing in this country.

Coloured Supplement.—The subject of the coloured plate to be published with the issue for next week is *Cypripedium Maudiae*.

THE KING AND THE "HORTICULTURAL RECORD."—HIS MAJESTY'S interest in horticulture, exhibited in such signal and gracious manner at the time of the opening of the International Exhibition, is again illustrated with equal graciousness by his acceptance—as announced in the following letter—of a copy of Mr. REGINALD CORY'S *Horticultural Record*, a work dedicated by special permission to HIS MAJESTY.

[COPY.]

"Buckingham Palace,

March 16, 1914.

"Dear Sir,—The King is delighted with the copy of the *Horticultural Record* which you have been kind enough to offer for his acceptance.

"His Majesty much admires the beautiful way in which the work has been prepared, in addition to its being an interesting history of the greatest International Horticultural Exhibition the world has yet seen.

"Yours very truly,

"(Signed) STAMFORDHAM.

Reginald Cory, Esq."

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held on the 7th inst., in the Vincent Square Hall, Westminster. At the 3 o'clock meeting of Fellows a

lecture on "The Cultivation of *Amaryllis*" will be delivered by Mr. C. R. FIELDER.

HORTICULTURAL CLUB.—The next house dinner of the Club will take place, at 6.30 p.m., on Tuesday next, at the Hotel Windsor, Victoria Street, Westminster, when Mr. P. AMAURY TALBOT will give a lecture on "The Flora of Nigeria," with special reference to 250 new flowers, lately discovered in that country. The lecture will be illustrated with photographs taken in Nigeria under Mr. TALBOT'S personal direction.

HORTICULTURE AND THE DRAMA.—The representation of a scene in the Chelsea Flower Show at the Drury Lane Theatre is a noteworthy event, even in these days, when the whole nation takes a practical interest in gardening. It goes to show how greatly horticulture has entered into the social life of the metropolis. The leading characters in "Sealed Orders" visit the show: quite the well-dressed throng of men and women that one sees at the spring exhibitions, and the view is in the big tent, with the mound of *Cinerarias* grouped around the obelisk and beds of flowers studding the green-covered parterre immediately surrounding it. On either side are great groups of tall Rambler Roses, and the general effect is certainly good, albeit, of course, it is produced with the aid of artificial flowers. The show is referred to frequently in the course of the piece, and scenes on the Embankment show the great posters advertising the exhibition. Horticulturists who go to Drury Lane to see the flower show scene will undoubtedly enjoy their visit.

BOTANICAL GARDEN FOR MICHIGAN UNIVERSITY.—The University of Michigan, at Ann Arbor, has come into possession of what will eventually be the finest botanical garden owned by any university in the Middle West. The old botanical gardens on the East boulevard will be turned over to the department of landscape design, to be used by them as a park or object ground in landscape design. The greenhouse now in the old botanical gardens will be moved to the new grounds and enlarged to accommodate the experimental work carried on. Work on these new gardens and greenhouses will be started this summer. *Florists' Exchange*.

FORESTRY AND THE PANAMA CANAL.—The genius for applying science to practical affairs which is so conspicuous in the American has been illustrated in many ways during the building of the Panama canal. Everyone knows, for example, of the successful war of extermination waged by Surgeon-General GORGAS, sanitary officer of the Panama Canal Commission, against the mosquitoes, which transmit malaria and yellow fever from one human being to another. We now learn that the enormous earth-slides at the Culebra cut and elsewhere in the course of the canal are likewise to be combated by the application of scientific knowledge. The forester is to be called in to check the earth-slides, and the traveller is promised that when he passes through the canal he shall voyage between banks green with vegetation instead of, as in the Suez Canal, between desolate banks of sand.

EARLY FLOWER SHOW AT BIRMINGHAM.—The annual Orchid and early summer show of the Birmingham Botanical and Horticultural Society will be held at the Botanical Gardens, Edgbaston, on June 11 next. Honorary exhibits of flowers, fruits and vegetables will be welcomed. Particulars may be obtained from Mr. T. HUMPHREYS, Curator, Birmingham Botanical Gardens.

PREPARING TREES FOR THE PANAMA-PACIFIC EXHIBITION.—Accounts in the horticultural Press of America present a vivid picture of the enterprise which is being bestowed on the horticultural features of the forthcoming exhibition. The site, which

a year ago was a barren waste of sand dunes and salt marsh, has been prepared, according to the *National Nurseryman*, by pumping from the bay of San Francisco millions of cubic yards of sand. After the land had been made up 25 million cubic yards of soil were pumped from the bed of the Sacramento river, transported 70 miles to the exhibition and spread in a layer of from 6 to 8 inches over the spaces between the sites for buildings. Gardeners have been despatched to all parts of the world in order to select trees for the groupds. Size and age appear to present no drawbacks, and transplantation is being effected on the side-box system. This system consists in cutting with a 7 feet knife 7-feet deep cuts on the four sides of the tree to be moved. Fertilisers are forced into the cuts, and outside the latter boards are placed. Six months elapse, during which time the tree is nourished by its main, vertically-descending roots, and the side shoots are forming fibres. The tree having recovered from the preliminary operations the bottom roots are severed, a bottom board is placed beneath the tree, and so a box is made. Among the trees which, as it is said, have been transplanted successfully by these means and shipped and established in the grounds are 200 rare Palms. One avenue is lined with *Dracaena indivisa* 18 feet in height; in another yellow Phoenix and *Washington robusta* are used. *Eucalyptus* from Australia, rising to a height of 28 feet, stand on either side of the west avenue.

ROTHAMSTED EXPERIMENT STATION: LAWES AND GILBERT CENTENARY FUND.—We would draw attention to the fact that the Lawes and Gilbert Centenary Fund is not yet closed, there still being £950 to raise before the new laboratories can be built. As our readers will remember, the Centenary Fund was established for the purpose of collecting £6,000 whereby to qualify for a Development grant of £6,000, and thus obtain a sum sufficient to erect and equip a laboratory at Rothamsted to replace the old laboratory, which, after nearly sixty years of use, is now too small, and unsuitable for modern requirements. The fund has been generously supported, subscriptions, large and small, having come in from Great Britain and Ireland, from France, Belgium, Holland, Germany, Spain, Canada (where the Federal Government gave \$500), United States, India and Australia. The committee is particularly anxious to clear off this last sum and to begin building operations at an early date. Subscriptions should be sent to the secretary, Rothamsted Experimental Station, Harpenden, Herts.

THE BANANA INDUSTRY.—In a recent article on the Banana Trade Development, published in the *Financial Times*, it is stated that during the past few years a sum of £7,250,000 has been expended on the construction of fifty-seven steamers for the conveyance of Bananas between the West Indies and England, and that the imports of this fruit into Europe are estimated at 850,000 bunches per month, while the trade is rapidly expanding. Developments are impending which will not only still further add to the amount of tonnage employed in this trade, but will also in all probability lead to a more widely distributed organisation in this country, with a view to expediting the delivery of the fruit to the consumer, in order to prevent the glut which at present sometimes occurs. The business has been found to pay handsomely, and capitalists are prepared to invest large sums in it.

EVER-BEARING STRAWBERRIES.—An article by Mr. C. F. GARDENER (see *American Fruits*, March 14) on the above subject cites the varieties Progressive, Superb and Americus as possessing good ever-bearing qualities. Progressive bears most fruit, Superb the largest berries, and Americus, which is at its best during August,

has the great merit that its flower-stalk stands nearly upright. They are all hardy and bear stamens. A defect of some of the best varieties—and that is, no doubt, an effect of their quality of continuous fruiting—is that they are runnerless. Hence they may be propagated only by division; but in this way from 12 to 20 plants may be obtained from each specimen.

A TRAP FOR THRIPS.—Experiments carried out by Mr. F. M. HOWLETT in India and described in the *Journal of Economic Biology* (IX., 1, March, 1914), indicate that various aldehydes have a marked attraction for thrips. Mr. HOWLETT experimented with benzaldehyde, cinnamylaldehyde, and other aldehydes of similar composition, and found that watery solutions of these substances served to trap thrips in considerable numbers. The liquid was used at the rate of half a pint of water to two

FIG. 105.—PRIMULA WINTERI ON A ROCKERY.

cubic centimetres of the aldehyde, and was exposed in small bowls. Benzaldehyde is cheap, and although the method in its present form does not at first sight seem to be very practicable, it is well worth trying.

"THE ANNALS OF THE BOLUS HERBARIUM."—We have received the first number of the new periodical which has been established in the interests of South African botany. In his foreword Professor H. H. W. PEARSON, the editor, points out that there is at present no South African journal devoted to the subject of botany, and he states that the first object of the new journal will be "to treat of botanical work inspired directly or indirectly by Dr. BOLUS, and with investigations conducted in or in connection with the Bolus Herbarium." The opening number, which has for a frontispiece a portrait

of the distinguished South African botanist, Mr. HARRY BOLUS, contains an account by the editor of the flora of the Great Karasberg; an instalment of an article by F. and L. BOLUS, entitled "Key to the Flora of the Cape Peninsula"; and a short notice on national Botanical Gardens. Two parts of *The Annals* will probably appear each year, and four parts will constitute a volume. The subscription is 15s. per volume, and the numbers may be obtained from the Cambridge University Press.

PRIMULA WINTERI.

I ENCLOSE a photograph (see fig. 105) of *Primula Winteri* growing in Mrs. Lockett Agnew's garden at Hallingbury Place, Essex. The plant was received in April, 1912, and planted out on the rockery at the end of June the same year. The soil is a rather heavy loam, and was lightened with a little leaf-mould. The plant has withstood the cold of two winters, including frost ranging from 10° to 15°, the only protection afforded being a pane of glass for the purpose of warding off the rain. The situation in which the *Primula* is planted faces due north, receives little or no sunshine, and is exposed to all winds. As will be seen from the illustration, the plant made vigorous growth and developed three large crowns last year. Mrs. Lockett Agnew, who is an enthusiastic grower of Alpines, considers that there is no doubt of the hardiness of this species. The square of glass in winter helps to preserve the beautiful white farina with which the foliage and flowers are covered. F. A. Cook.

NOTES ON RHODODENDRONS.

ASSUMING that special societies are needed to guide and control the zeal and activities of cultivators of important genera of garden plants, it is surely time we had a *Rhododendron* Society. The genus is a most important one, and now that such a large number of Chinese species have been introduced into cultivation, we may expect further developments, especially from those who take an interest in raising hybrids. Certainly among the Chinese *Rhododendrons* there are characters which are new to the garden representatives of the genus; that is evident enough in the species which have flowered, and, judging by their foliage and habit, as well as by dried specimens, characters still more striking will be revealed by others as they flower. It is to be hoped that the work of identifying these new introductions will be entrusted to Kew or to some equally competent authority. A plant may be new to cultivation and yet well known in herbaria, and it is unfortunate when plants are exhibited, perhaps certificated, and recorded by the horticultural Press under names which subsequently prove to be wrong. There is an easy way to avoid this, and *Rhododendron* fanciers are urged to follow it.

Names are, and always will be, a source of confusion and annoyance, as, for example, in the case of *Rhododendron Cornubia*, shown by Messrs. R. Gill and Sons, Falmouth, in March, 1912, when it obtained an Award of Merit, and shown again a fortnight ago by Mr. R. Fox, Penjerrick, under the name of *R. Lilianii*, and again given an Award of Merit (see *Gardeners' Chronicle*, March 14, p. 191). Clearly the name *Cornubia*, a most appropriate one, must stand. This hybrid originated at Penjerrick, it is said, from *R. arboreum* crossed with hybrid *R. Shilsonii* (*barbatum* × *Thomsonii*), and Messrs. Gill obtained their plants from that source. It is doubtful to me if *R. arboreum* really was one of the parents, but whatever its origin the plant

is one of the very best of the crimson early-flowering Rhododendrons.

What glorious plants some of the Indian Rhododendrons are! Two of the handsomest were shown last week—namely, *R. grande* (argenteum) and *R. Nuttallii*—the former a tree in Sikkim with leaves a foot long, dark green above, silvery beneath, and enormous ball-like trusses of bell-shaped, waxy-looking flowers, each 2 inches long and wide, white with a blotch of crimson at the base. This species is hardy enough, but unfortunately it pushes into new growth and flowers too early to escape our late spring frosts. This is true of the majority of the Sikkim species; they do not object to mid-winter frosts, but they are hard hit by those of spring.

The other species, *R. Nuttallii*, shown in perfect condition by Messrs. Gill, astonished many who, seeing it for the first time—for it is rare in gardens—could scarcely believe that it had been in gardens over half a century, and that it can be grown in an ordinary greenhouse where Camellias and Indian Azaleas are at home. Being a native of Bhotan, at an elevation of 4,000 to 5,000 feet, it requires more warmth than the Sikkim species do. At Falmouth it is grown in a greenhouse from which frost is excluded. Like *R. Dalhousiae*, it often grows as an epiphyte on large forest trees, but they both thrive in the open border, and if the shoots are stopped with judgment they form fairly shapely bushes. *R. Nuttallii* has leaves 8 inches by 4 inches, and fleshy, bell-shaped, cream-yellow flowers 5 inches long and wide, fragrant, altogether charming. They are borne in clusters of five or six at the ends of the strong shoots.

A hybrid now flowering at Kew, but originally from the collection of the late Mr. J. H. Mangles, Haslemere, had for its parents *R. grande* and *R. niveum*, the latter having very compact, rather small heads of lilac-purple flowers. The hybrid, for which the name *R. grande niveum* is proposed, is intermediate in characters between the two parents, the flowers being about 1½ inch long, and their colour pale mauve, pleasing as to shape and hue, and quite worthy of its raiser, to whom Rhododendron fanciers are greatly indebted for much excellent pioneer work in the eighties as a breeder and cultivator of the best species of the genus.

R. sutchuenense is flowering now in several collections, proving that it will have to be placed among the species that flower too early in the year to be safe. It first flowered in Messrs. Veitch's nursery at Coombe Wood in 1910, the plants being quite small. It has large leaves, up to 10 inches by 2 inches, dark green above, glaucous beneath. The flower heads are large and compact, the flowers being as large as those of *R. grande*, but with only five corolla lobes. They are rose-pink, with small red spots on the upper part inside. W. W.

THE BULB GARDEN.

FOUR GOOD DOUBLE TULIPS FOR FORCING.

CERTAIN double varieties of Tulips are unsuitable for decorative purposes, owing to their weak stems. The following four varieties have strong, upright stalks and flowers of good colour and substance. They are valuable either for furnishing cut blooms or for decorative purposes in dwelling-rooms:—Murillo, height 14 inches, colour deep blush; Vuurbaak, 12 inches, scarlet, shaded crimson, a brilliant variety; Rosalie, 10 inches semi-double; deep rose-coloured flowers; and La Candeur, 12 inches, pure white. These bulbs may be purchased cheaply, and the varieties are all suitable for growing in quantities. James Winchester, Windle Hall Gardens, St. Helens.

RIBES LAURIFOLIUM.

I VENTURE to predict that the evergreen Ribes, *R. laurifolium* (see fig. 106) is destined to take a prominent place in gardens, for it is probably one of the choicest treasures sent home from China by Mr. Wilson. It is a strikingly handsome plant all through the winter and early spring, and suitable for planting on boulders in the rock garden. Long before it is in flower the plant is interesting and beautiful, and it remains in flower for several weeks. The severest weather we have had here during the past three years has not injured the blossoms in the slightest degree. The colour of the petals is a

ber-ship is constantly increasing, and I am glad to say that the amount of its subscriptions shows a similar growth. There is no society that does not make mistakes in the first years of its career, and it is useless when a society has achieved success to enter into recriminations as to who is responsible for past errors. Mr. Hall's remarks as to lack of tact and courtesy and a policy of isolation are quite contrary to fact, and as to the future I am hopeful that his pessimistic prophecies will not be fulfilled.—*J. C. Jackson, hon. secretary.*

—I fear my friend Mr. Cuthbertson has not understood that I was not criticising the R.H.S., but rather criticising the policy of those who drew up the by-laws of the N.E.H.S., in that they made a mistake in forgetting that regula-

FIG. 106.—RIBES LAURIFOLIUM: FLOWERS GREENISH-YELLOW.

very pale yellow passing to greenish white. *E. Beckett, Aldenham House Gardens, Elstree.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE N.E.H.S.—I have read the letter of the Rev. J. Bernard Hall in your issue of the 21st ult. (see p. 207), and at once write to contradict many of the statements contained therein. I do not consider it necessary to go into every point raised by Mr. Hall, and in the first place I should like to state on behalf of the Council, that never since the society was initiated has it been in a more healthy condition than it is at the present time. Both the Council and the various committees are composed of gentlemen who have a large and varied knowledge of horticulture in all its branches. The list of mem-

tions which were all right for London, and the headquarters of British horticulture, were not at all suitable for a young Northern society struggling to exist under quite different conditions, and severely handicapped and limited in many ways, e.g., the existence of strongly established societies, who, quite rightly, view the N.E.H.S. as simply a competitor. The word "co-operation," to my mind, has been overlooked, and the policy of co-operation never seriously attempted. A "North of England Association of Horticultural Societies," to my mind, implies the only policy that is likely to succeed. Leeds is the natural headquarters of such an Association, as witness the fact that commercial travellers and bootmakers make it their base. But to limit the operations to Leeds is not only suicidal, but also dead against the policy to which Article II. commits the Council, i.e., "the society is established to promote and encourage every branch of horticulture in the North of England." We have no sign that the

"new arrangements" are anything but further proof of the Leeds bias which has so seriously handicapped the Society so far. I regret having to publicly criticise the N.E.H.S., but I feel, and I am in good company, that someone must speak out since constitutional methods have failed. As regards the R.H.S. not helping the N.E.H.S., without mentioning much valuable help given after, and even before, the N.E.H.S. was inaugurated, I may point to the hard cash spent on, and the exceptional treatment accorded to, the Society at Harrogate (1911) and Newcastle (1911). I only want to stir up the N.E.H.S. to be "true to name" and loyal to Article II. *J. Bernard Hall, Farnham Vicarage, Yorkshire.*

AQUILEGIA STUARTII.—I am much obliged to Mr. George M. Taylor for the valuable information he gives me on page 223 of the *Gardeners' Chronicle* regarding the origin of this beautiful *Aquilegia*; which, when it was sent to me by its distinguished raiser, I did not find quite so easy to cultivate successfully as many other varieties. Dr. Stuart assured me that "it was not grown by everyone; requiring very careful attention in its earlier stages, and a deep, fertile soil." That *A. Witmannii* was one of its parents, and not *coerulea*, I have now no doubt. *David R. Williamson.*

MISTLETO ON THE COMMON HAZEL.—On one of the farms on the Madresfield estate by the side of a small stream there is a fine, healthy plant of the broad-leaved variety of Mistleto growing on the top of a common Hazel, *Corylus Avellana*. This appears to me a very uncommon host plant, and as none of my friends with whom I have corresponded has seen or heard of Mistleto growing on such a foster parent, I write to ask whether such an occurrence has been recorded before. *W. Crump, Madresfield Court Gardens, Malvern.*

NARCISSUS FLY—EUMERUS LUNULATUS (E. STRIGATUS).—I have read the note by Mr. A. J. Bliss in the *Gardeners' Chronicle* of the 28th March. Agreeing with him that it would be very desirable that the matter should be thoroughly investigated under scientific conditions, I think that, until this shall have been done, it would be well to reverse our usual judicial practice, and to consider the accused to be guilty until he has been proved innocent. Optimistic anticipations of scientific conclusions not yet arrived at are doubtless cheering, but they may be also dangerous should they deter some from taking in time precautions which, later, science may definitely show to have been necessary. And, looking at the alarming rapidity with which this fly increases this is the more important. Mr. Bliss is apparently satisfied that the grubs of the *Eumerus lunulatus* are merely "scavengers," feeding, not on the living tissue of the bulb, but on the excrement of the *Merodon equestris*, or on the dead and rotting substance of the bulb. For the following reasons I think it would be unsafe to accept this conclusion as proved. Taking, first, the association of the *Eumerus* grub with that of the *Merodon*, Mr. Bliss tells us that he has "taken up this spring a dozen or more Daffodil bulbs which contained *Eumerus* larvae, and in every one of them there was also a *Merodon* grub." Well, during the same period, I have taken up very considerably over 100 bulbs, and found in them (and they were carefully examined, and generally cut open) only two grubs of the *Merodon*, nor did the other bulbs show evidence of their previous occupation by that grub. Fortunately my garden has not appreciably suffered from the *Merodon*. For these reasons it would seem that a close association of the *Eumerus* with the *Merodon* is uncertain. Obviously the grub of the former feeds on something else than the excrement of the latter. Taking the second point, namely that the *Eumerus* grub may be feeding on the dead and rotting substance of the bulb, resulting from some fungus, or other disease, we have here, in the absence of scientific proof, more room for speculation; but as a foundation for my speculation I have to regard the fact that in an immense majority of cases I find that the bulbs attacked this spring by the *Eumerus* had been in the previous year absolutely strong and healthy. In a single row of last year's healthy

bulbs "one has been taken and the others left." Again, the bulbs attacked have been those in places fully exposed to the sunshine; those under the shade of trees have been left untouched, and many of these have been lifted for examination. The suggestion is that the *Eumerus lunulatus*, like the *Merodon*, is a "sunshine fly." And, again, where do these grubs, "scavenger" or otherwise, which are found in the bulbs, come from? The parent is a fly, about the size of an ordinary house fly, and, of course, lays its eggs. But where, in the case of the *Narcissus*? It can be understood that in the surface rhizome of the *Iris* the fly can easily deposit its eggs, but in the case of the *Narcissus*, with bulbs some inches below the surface of the soil, the *modus operandi* is not at all so clear. In no case, although very careful examination has been made, have grubs of the *Eumerus* been found in the adjacent soil. That the grubs travel I think is beyond doubt; but when, as was the case of a single bulb of var. *Glory of Noordwijk*, no fewer than 100 grubs were found (not one occurring in bulbs closely adjacent to it), where did these same grubs come from? Is it easier to imagine that from all surrounding parts this army of grubs made journeys, having for their object a "dead set" at this particular bulb, previously a perfectly healthy one, or that their presence showed that the eggs were deposited by one or more flies in the foliage of that particular plant during the previous season, as is the case with the *Merodon*, with which the *Eumerus* is closely allied? And pursuing the analogy, why then should not the larvae of the *Eumerus*, as does that of the *Merodon*, work down to the bulb and attack direct? Of course, nothing either way is as yet conclusive; but I would suggest that until scientific investigation has thrown more definite light upon the subject it would be the safer course to lift all doubtful bulbs for examination, and so help to get rid of the pest as far as possible. *Charles E. Shea.*

SUGGESTIONS FOR OBSERVATIONS ON THE ORDER OF BLOSSOMING OF DIFFERENT VARIETIES OF FRUITS AND EXPERIMENTS IN THEIR POLLINATION.—(1) Note the order of blossoming of different varieties of Apple, Pear, and more particularly of Cherry and Plum, also note length of time varieties are in flower; with the object of seeing which varieties are in flower about the same time for cross-pollination. (2) In order to test which varieties are self-fertile and which are self-sterile enclose trusses of unopened flowers in paper or muslin bags, and tie at the base; when the tree is in full flower open the bags; pollinate the blossoms with pollen of the same variety by dusting stigmas either with pollen of the anther held by forceps or by a camel's hair brush, and replace bags. Remember to sterilise the brush by dipping in methylated spirit and allowing to dry before using with another variety. Label bags with date, what has been done, and keep notes till fruit is mature or has fallen. (3) An interesting experiment is to place three bags over trusses of unopened flowers on a variety, and treat them as follows:—(a) Leave alone to see if any fruit sets with insects excluded; (b) pollinate with own pollen to see if fruit will set with its own pollen; (c) pollinate with pollen of another variety to see whether a better result is obtained with foreign pollen. Each trial should be labelled, the bags may be removed about ten days after pollination, when all the petals have fallen; make notes of what happens until the fruit is ripe. (4) To find the best pollenisers, especially for shy-bearing varieties; unopened blossoms to be bagged may be emasculated (by pulling or cutting out the anthers before they shed their pollen), or if the variety is self-sterile it may be left untouched. The bagged flowers when the tree is in full bloom are pollinated with pollen of another variety; in order to give the best chance the flowers may be thinned (say to 3 for Apples and Pears, 5 for Plums, and 10 for Cherries), the number of flowers pollinated should be stated on the label, and notes may be made fortnightly. (5) Notes may be made of the insects chiefly seen at the different fruit blossoms for comparison in different parts of the country. (6) Note may be made of any varieties that crop badly in order to test another year as to

whether the cause is lack of suitable cross-pollination. Observations and records of experiments should be sent to the secretary, National Fruit Growers' Federation, 2, Gray's Inn, London, W.C., at the end of July. The results will be tabulated and summarised, and a copy of the report will be sent to the contributor and to the *Gardeners' Chronicle* for publication. *C. H. Hooper.*

FEBRUARY RAINFALL (pp. 157, 223).—Mr. Thomas Newman will be surprised to hear that the rainfall in these gardens for February amounted to 7.62 inches, thus easily beating his record. Rain was recorded on twenty days of the month, the heaviest fall in twenty-four hours totalling 1.40 inch, which occurred on the 7th. Our altitude is 550 ft. above sea level. During March rain fell on every day, excepting two, up to the time of writing (27th). The record for March so far is 5.76 in. On our heavy clay soil such excessive rains throughout February and March year by year greatly retard outdoor gardening operations. This place is situated some 20 miles from Swanmore, and having compared the rainfall from time to time with that observed by Mr. Molyneux at Swanmore Park, we find that ours is invariably the heaviest. In fact, according to the meteorological returns, this appears to be the wettest spot in Hampshire. *Wilmot H. Yates, Rotherfield Park Gardens, Alton.*

—In January, 1913, at Bournemouth, we recorded 5.97 inches of rainfall, and in February 1.89 inches. The average for January is 2.57 inches, and February 2.35. The total for the year amounted to 33.78 inches, against 31 inches. In January this year we registered 0.49 inch, and in February 4.56 inches. In February, 1910, we had 4.32 inches, and in 1912 2.75 inches. The total for the year was 43.20 inches. In February this year we had 11 dry days. I find the greatest amount which fell in February in Bournemouth was in 1900 with 5.52 inches. I recorded in February this year .79 inch on the 8th, .40 inch on the 11th, .62 inch on the 14th, .45 inch on the 15th, .60 inch on the 18th, .59 inch on the 21st inst., and .56 inch on the 22nd at 9 a.m., so that most of this occurred on the previous day. Of seventeen days I registered the same amount of rain as that stated by Mr. Thos. Newman. It is generally understood that the greatest amount of rain falls on the top of hills, except in the case of mountains, but I generally record more rain at 41 feet above sea-level than at my own house 145 feet above. It greatly depends upon the surroundings. My garden is pretty open, at the lower station it is walled in, and there are trees all round, but not in the way of the rain gauge; that is to say, the angle allowed is all-sufficient in all the stations. The third gauge was on the cliffs at exactly the same elevation—41 feet—but very exposed, and the wind blew much of the rain away. Another gauge by another observer is also on the cliff edge within 20 or 30 feet. One year these agreed to within .01 (one-hundredth) for the year. They were both the lowest records in Bournemouth. One was within a few hundred yards of the highest recording gauge. These two gauges on the cliff are situated, one at 41 feet, the other quite 100 feet above sea-level. We have had 5.12 inches this month, against an average of 2.37 inches. *C. Dales, Meteorological Registrar, Bournemouth.*

GARDENING FOR THE BLIND.—Now that so much interest has been aroused on behalf of the blind through the opening of the new National Institute for the Blind by the King and Queen, it may interest your readers to know that the blind have a book on gardening published in Braille. It is entitled *Gardening Notes*, and is a reprint from monthly notes contributed by myself to the blind magazine, *Progress*. The notes aroused a lot of interest at the time, and they were afterwards published in book form, by request of blind readers. I receive numberless letters from blind readers—transcribed from Braille by the Editor—asking questions upon gardening matters, questions which show such intelligence that would put many sighted "gardeners" to shame. Amongst the questions asked were "What is the difference between a Pansy and Viola?" and "Which is the best way to

propagate *Rhododendrons*? One might wonder how should these matters interest blind persons? One blind man wrote to say: "For some years my gardening work has been to weed Onion beds, but through reading these notes I became ambitious, and after getting a half-inch board, sixteen feet long, and six inches wide, four stakes and a yard stick, made out of a broom shaft, with the aid of these I dug a piece of ground in September, using the board for a guide, with the stakes in the ground behind to prevent it working away, turning the board over after every length was dug. The piece of ground dug was 24 yards by 8 yards. On this I sowed my *Cabbage seed* (*Flower of Spring*), and in October I had an unlimited supply of plants. Again using my board I made thirteen trenches, in which I planted eleven score, and on the flat four score plants. At the beginning of the year I intend putting in other crops." When writing my notes on flowers I was urged by the Editor not to confine myself to flowers having scent, but to recommend some having colour, because the chief joy of a blind person is to give pleasure to others. If any of your readers should have any subject at any time likely to prove of interest to blind people, let him send it to the Secretary-General, National Institute for the Blind, 206, Great Portland Street, W. It would be appreciated, and would help to give a little light to the blind. One blind gentleman told me—so recently as last Christmas—how he cut out and made a flower bed on the turf, taking the design from the back of an old watch. When the bed was finished he was not more than two inches out. He planted it entirely himself, with green and golden Yews, graduating the heights to the edges of the bed. *F. C. Stainsby, Brocklesby Park Gardens, Lincolnshire.*

ARBUTUS MENZIESII.—It was interesting to read the notes on *Arbutus Menziesii* (syn. *A. procera*), at Bayfordbury (p. 182), and Bassett Wood, Southampton (p. 207). There is a tree growing here, planted by my employer, J. C. Hawkshaw, Esq., in February, 1880, which at that time was about 1 foot high, and now measures just over 30 feet in height, and 2 feet 6 inches at 3 feet from the ground. This tree appears to have much the same habit as the specimen figured on p. 182, with the exception that it has two large branches proceeding from the main stem within a few feet of the ground. It is not so upright in habit, owing to being overshadowed by a large Oak and a Yew, on the north and north-west side; these have driven the *Arbutus* much out of the perpendicular. It flowers very profusely most seasons, but I have failed to notice it bear fruit during the past twenty-two years. It is interesting to learn that the specimen at Bayfordbury produces masses of orange-red berries. The answer to the query put by my brother will be looked forward to with interest. The reddish papery bark is shed annually, often coming away in large strips; this makes the tree a striking object. *Arbutus Unedo* and *A. canariensis* I have raised from seed. Plants of the former species have now reached the flowering stage; seedlings of the latter were only raised in 1913, therefore are still small. These have, however, withstood 22° (F.) of frost without protection or the slightest injury. *Walter Silcock, Hollycombe Gardens, Liphook, Surrey.*

BIRDS AND THE FRUIT CROPS (see p. 223).—With regard to your correspondent's suggestion to place receptacles containing water near to the trees and bushes carrying crops of ripening fruit, as a means of preventing, to a certain extent, the destruction of the fruit by birds, I may state that we have planted alongside a stream of excellent water, from which birds can easily obtain all the water they require, a row of bush Apples, including the varieties Gladstone and Ribston Pippin, also an old standard tree of a Russet sort. I find, however, that I cannot keep the blackbirds and tits away from them; in fact without netting the trees I cannot keep a single fruit long enough for it to ripen. I have known blackbirds to tear holes in old fish netting in order to get at the fruits. Moorhens also cross the stream and eat the fallen Russets, of which they appear to be particularly fond. *Henry F. Moulden, Gardens, Bishopstrow House, Warminster.*

'JOURNEYMAN GARDENERS' WAGES.—

The correspondence on the question of journeyman gardeners' wages has not revealed any serious faults in the system prevailing generally. There will always be individual cases of hardship in all occupations, and although they ought not to be allowed to exist, so long as human nature remains what it is we shall never attain to ideal conditions. The chief grievances seem to be (1) bad accommodation in bothies; (2) low wages; (3) excessive hours. In regard to (1)—bad bothies—there is no excuse in any way whatever for their continuance, and I imagine the cases where they exist are very few. Every head gardener who has a spark of humanity in him ought to see that his men are comfortably housed. If he does not do so, the first step should be to remind him of it, and I cannot imagine it would be taken in vain. But, if it proves useless, there are other ways of bringing pressure on the powers that be; and there is a Gardeners' Association whose secretary keeps a black list of all places which for any reason do not come up to a respectable standard. Members can always obtain advice and assistance, including legal assistance if necessary, in anything connected with their employment on applying to the secretary. (2) Low wages.—While the profession is so overcrowded wages are certain to vary considerably, but there are signs of much improvement. Many factors are at work which will help in this matter. The recent arrangements for granting diplomas to professional gardeners through the Royal Horticultural Society will do much to lift the profession out of the ditch into which it was falling. Some will doubtless say that they do not believe in examinations. Neither do I count on much benefit from written examinations alone; but we must remember practical and oral examinations are now to be added to the theoretical ones, so that point will be complete, and will sift out some of the chaff. Eventually the best positions will be filled by those who have obtained the diploma, and they will have a good reason for asking a suitable salary. The general tendency is for wages to rise in all employments, and this is certain to have some effect on gardeners, because some of the young men will leave for more remunerative work. Other matters that will help are the increasing demand for men in public parks, moderate sized gardens, trade establishments, and county council work. The average wages paid to young gardeners are not really so low as they appear to be. If the bothy attendant is a capable person, and garden produce is allowed to the young men (as it should always be), the amount spent on board will be much less than a tradesman in lodgings has to spend. If the latter gets 6s. or 7s. per week more money he is no better off. There is a great difference in the way young men use their money, and many would often benefit themselves by studying this point. (3) Excessive hours.—Improvements are taking place in this aspect of the question, and the Saturday half-holiday is becoming general, but there is cause for some complaints. I have myself known head gardeners who have kept the young men working overtime, merely because they wanted to grow produce for shows, and have not given them a halfpenny for their assistance. Such treatment cannot be too strongly condemned. All overtime should be paid for. It may occasionally be necessary, and when a sudden pressure of work, such as Grape-thinning, comes, it is impossible to avoid it, but I am certain neither master nor man derives any benefit from it, and it can only be classed as a necessary evil. But there is no reason why a gardener should not be paid for it. Where is any other wage-earner to be found who works overtime without payment, and where is the justice in paying one and not another? It is even worse in establishments where produce is sold and the men are worked overtime without payment. Thirty years ago, if journeymen had written we should have had more complaints, and at that time there was ample excuse for them. This shows that things are improving. Although it has not been definitely stated in this correspondence, I consider the absence of any reasonable chance of promotion for many of our young men is one of the worst faults of our present system. It is absolutely impossible for all journeymen in this kingdom to obtain foremen's positions, and eventually head gardeners' situations. I may perhaps

be told that all are not fitted for promotion, but many are who have to leave for other occupations or go to other countries; this constant overcrowding causes a large number to apply for vacant posts, with the inevitable result of low wages and other adverse conditions. Those who wish to remain and succeed in the profession should use every means in their power to excel the gardeners of the past. I must confess a want of confidence in them on this point; there are too many other attractions in the present day, and study is often neglected. But in order to gain a useful knowledge of the science which underlies all garden work, books should be studied systematically, and this must be done after working hours throughout the year. I do not mean that all games and recreation should be given up, for they are useful to a certain extent, but they should not be pursued at the expense of the necessary studies. One hour at the books with determination to succeed, followed up regularly each night, will give excellent results, and will sometimes induce two hours to be given. This is strictly necessary in order to excel. It will never take the place of practical work, but the knowledge thus obtained will be helpful when difficulties occur in after years. School trained men will never equal those who have been apprenticed and trained in good private gardens, if the latter endeavour to add to their practical knowledge enough science to gain the diploma. —*W. H. Divers, V.M.H.*

—Low wages in a garden usually accompany shortage of staff, and consequently the work is hard and the hours long. Let *Contented Journeyman* work under a strict head gardener where these conditions prevail or put in three months at a nursery at the usual journeyman's wage (9s. a week). I doubt whether he would still be "contented" then. *Hard Graft.*

—The absorbing interest taken in his work is oftentimes the gardener's undoing, instead of his making, as implied by Mr. T. Smith (see p. 224). Compensations there are to the man who loves his work, but he must not be selfish, otherwise he is banned for neglecting his family! Hence the need for the betterment only achievable collectively. Ignoring cheap sneers at traits to which humanity is liable, it may interest Mr. Smith to learn that some beings exist who believe they are men and are content to remain manly rather than become mere prattlers. Even our critics are gregarious, but we must not be, except in those relations of life which meet the approval of Mr. Smith. *Wm. H. North, London Branch Secretary, B.G.A.*

—Mr. Smith is like many more who pretend to be antagonistic to the B.G.A., yet fail to give sound reasons for remaining outside the ranks. His remarks on the aspiring young men will no doubt receive the consideration they deserve. Perhaps Mr. Smith would not object to being paid for his overtime; for myself, I might have been much better off had I received only 3d. per hour for overtime, spent for love of my profession. At the present time there seems to be very little room at the top, and one of the reasons given is that there are so many interlopers; yet there are those who realise this but will not join any movement to alter it. All through this discussion a hopeless position seems apparent; but what has been the remedy in many other trades and professions? Those concerned have joined together in an earnest effort to bring about better conditions. I would like to point to the Teachers' Union, which is a similar organisation in many respects to the B.G.A. There is a tendency in all directions for amalgamation for the protection of interests, and why should not gardeners do the same? In the medical profession those at the top of the tree evidently do not refuse to join their powerful Union because there are others not so far advanced. *A Member.*

PUBLICATIONS RECEIVED.—*Lloyd's Beautiful Garden Flowers.* (London: "Lloyd's Weekly News.") Price 6d. net.—*The Carnation Year Book, 1914.* Published by the Perpetual Flowering Carnation Society. Secretary, T. A. Weston, St. John's Road, Orpington.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MARCH 24.—*Present*. Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair). Drs. A. B. Rendle, F. Keeble, Professor G. S. Boulger, Canon W. W. Fowler, Messrs. J. Ramsbottom, W. Hales, R. Hooton-Pearson, J. T. Bennett-Poë, A. Worsley, W. C. Worsdell, E. M. Holmes, and F. J. Chittenden (hon. sec.).

Malformed Fuchsia.—Mr. W. C. WORSDELL reported on the malformed flower of *Fuchsia* shown at the last meeting which had three partly foliaceous sepals, two of which had their stalked bases decurrent down the side of the ovary; one petal in form of a pitcher, with imperfect pollen sacs on one margin, and another petal one-sidedly developed and fused by one edge to the next, with a complete anther at the apex. Two of the stamens were excessively rudimentary, and two others were fused by the whole length of the filaments to the upper side of the half-formed anther-bearing petal.

Small Narcissus fly.—Mr. CHITTENDEN said that apropos of the suggestion that soaking *Narcissus* bulbs in water for a couple of days would destroy the larvae of *Eumerus strigatus*, he had kept some submerged in water for 72 hours and after removal from the water they soon became as active as before immersion.

Hippeastrum hybrid.—Mr. WORSLEY exhibited the flower of a hybrid *Hippeastrum* which had *H. calyptratum* as one of its parents. Like that plant it had ligular outgrowths near the bases of the perianth pieces, but smaller, and fringed with hair.

Aphides on Picea.—Mr. CHITTENDEN showed specimens of the *Lachnus* which has done so much damage to Spruces in some parts of England during the past few years. When the specimens were collected from *Picea pungens glauca* on March 16 the stem-mothers had already produced viviparous young, and had apparently been hatched about three weeks or a month. He had found a nicotine wash thoroughly applied the most effective agent in destroying the pest. Attacked trees soon show the needles brownish about the parts attacked by the greenfly, and this is quickly followed by leaf fall. Various species of *Picea* are attacked by the aphid.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 12.—*Committee present*: Rev. J. Crombleholme (in the chair), Messrs. J. Bamber, J. Cypher, A. G. Ellwood, J. Evans, J. Lupton, A. A. McBean, D. McLeod, W. J. Morgan, C. Parker, W. Shackleton, H. Thorp, A. Warburton, Z. A. Ward, G. Weatherby, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Cattleya Trianae F. McBean, *Cattleya Suzanne Hye de Crom* var. "Magnifica," and *Odontioda Diana* var. "Leena," all from W. R. LEE, Esq. *Odontoglossum Mirum* (Wilekeanum × crispum), *Odontioda Schroderae* var. "Walton Gem" (Bradshawia × crispum Oakwood Ruby); *Cattleya Trianae* var. "Walton Monarch," all from WM. THOMPSON, Esq.

Cymbidium Pauwelsii giganteum, from JOHN LEEMAN, Esq.

Odontoglossum crispum Eugenie, from J. BUTTERWORTH, Esq.

Odontioda Mrs. R. Le Doux (Bradshawia × Wilekeanum), from R. LE DOUX, Esq.

AWARDS OF MERIT.

Cattleya Trianae Mirabile, from WM. THOMPSON, Esq.

Sophro-Cattleya-Laelia Marathon, "Lee-man's" var., and *Cypripedium Griffin* No. 2, from JOHN LEEMAN, Esq.

Odontoglossum Siren (Pluto × Etna), from R. ASHWORTH, Esq.

Laelio-Cattleya Dulce (*Cattleya Mendelii* × *Laelia anceps Sanderiana*), from MESSRS. SANDER AND SONS.

SHROPSHIRE HORTICULTURAL.

MARCH 14.—There was a good attendance of members of the Shropshire Horticultural Society at the annual meeting, which was held on the 14th ult. The President (Mr. E. B. Fielden), in the absence of Mr. W. E. Litt (chairman of the committee), read the annual report, which stated that the committee had once more to congratulate the society on the splendid success of the summer show of 1913, which was in almost every particular a record. The income from all sources was £6,245 3s. 7d., and the expenditure was £4,585 Os. 8d., showing a profit balance of £1,660 2s. 11d. The previous best year's profit was £920 in 1905. It would be seen, therefore, that the show in 1913 was the greatest summer show ever held by the society. The rock gardens were only a partial success, owing to the show being so late in the season. It had been decided this year to introduce a new class for "formal or informal gardens." The subscriptions for the year had been well maintained, and the sale of cheap tickets formed another great record in the society's history. Allusion was made to the valuable services rendered the society by Mr. H. W. Hughes in the face of great difficulties, and to those of Mr. W. G. Brazier, the secretary, of whose untiring energies too much, it was stated, could not be said in praise. The death of the late Annabella Lady Bonghey, who had consented to act as President for 1914, was a great loss to the society. Her ladyship had promised to present a 50-guinea challenge vase for Carnations, and a further sum of 50 guineas to increase the prize money in the flower section. However, the assurance of Lady Bonghey's nephew, Mr. W. A. L. Fletcher, had been given that her ladyship's wishes would be carried out.

Mr. E. B. Fielden was re-elected President, and the retiring members of the committee were re-elected, with the exception of Mr. H. J. Hearne, in whose place Mr. Harold Cock was elected.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending April 1, 1914.

The Sunniest and Warmest Day as yet this Year.—The last two days were the warmest of the year as yet, but previous to this, moderate temperatures, as a rule, prevailed. On the coldest night—that preceding the 28th ult.—the exposed thermometer registered 12° of frost, and on the two warmest days the temperature in the thermometer screen rose to 64°. The ground is at the present time 1° warmer at 2 feet deep, and 3° warmer at 1 foot deep, than is reasonable. Rain fell on five days, and to the total depth of ½ inch. The percolation through both the soil gauges is declining, but during the week two gallons of rainwater have come through the bare soil gauge, and 1½ gallons through that on which short grass is growing. The sun shone on an average for 3½ hours a day, which is half-an-hour a day short of the usual duration at the same period of the spring. Yesterday (31st ult.) was the sunniest day of the present year as yet, when the sun was shining brightly for 9½ hours. Light airs and calms alone prevailed during the week. There was about a seasonable amount of moisture in the air at three o'clock in the afternoon.

MARCH.

The Wettest March for 53 Years.—The first half of the month was, as a rule, very warm, but during the latter half, with the exception of the last day, there were no warm days, and but four warm nights. Taken as a whole, this was a warm March. On the warmest day the temperature in the thermometer screen rose to 64°, and on the coldest night the exposed thermometer registered 12° of frost. Both these extreme temperatures are high for the month. Rain fell on as many as twenty-four days, and to the total depth of 4½ inches, making this the wettest March during the past fifty-eight years—that is to say, as far back as the Berkhamssted rainfall records extend. The number of rainy days was nearly as remarkable. At no time during the month were there two consecutive days without rain. Snow fell on six days, and on one day the ground was covered by it for a short time to the depth of 1½ inch. The sun shone on an average for three hours a day, which is half-an-hour a day short of the average duration for the month. There were as many as eight days on which no sunshine at all was recorded. The winds were, as a rule, rather high, and in the windiest hour the mean velocity reached twenty-six miles, direction W.N.W., which is the highest velocity recorded here in March for eighteen years. For only four hours during the month was the direction of wind from any point between north and east—the average duration in March for those winds being 197 hours. In no previous March—that is to say, for twenty-eight years—has there been so little north-easterly wind. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 4 per cent.

MARKETS.

COVENT GARDEN, April 1.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salemen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

REMARKS.—Supplies generally are shorter, and this week there is a large demand for flowers for the great Welsh festival on Palm Sunday. Next week is the busiest of the whole year in the flower trade, and we may expect prices to rise considerably. The subjects most in demand at Easter are Richardias, Liliums, white Roses, Tulips, Spiraeas, Azaleas, Lily-of-the-Valley, and Narcissus Poeticus. There is every prospect

of a plentiful supply of these subjects. Carnations are arriving in a better condition, the blooms being much finer in quality. Roses show the biggest increase, and these are sold at much lower prices. The supplies of flowers from Guernsey and Sicily are becoming considerably less, owing to the crops of Narcissus and other Daffodils finishing. The supply of Irises is still limited. Lilac from Holland is arriving in a good condition, and there are good flowers of White Stock, Marguerites, Star of Bethlehem, a few Anemones, and Parma Violets. Single Violets are finished for the season.

REMARKS.—There is every prospect of a busy time in this department during the next week. There are good White, Blue and Pink-flowered Hydrangeas, White Spiraeas, Genistas, Cinerarias, White Ericas, Lily-of-the-Valley, Lilium Harrissii, White Marguerites, and white and coloured Hyacinths. Well-grown pot plants of Stocks are the latest addition in this market. Ferns and Palms are improving in quality.

REMARKS.—Consignments of fruits from Cape Colony received this week per s.s. "Kinfauna Castle" amounted to about 19,000 packages, consisting principally of Pears and Grapes. The Australian Apple crop is reported to be a very good one this season, and some fine fruits are expected to arrive shortly from Tasmania, Victoria, West and South Australia. Varieties to hand consist of Jonathan, Monro's Favourite, Cox's Orange Pippin, and Gravenstein. Both from English and Continental growers there are shorter supplies all round of black Grapes. Forced Strawberries are becoming more numerous daily. A few fruits of green Figs are on sale. Asparagus continues to arrive in a fine condition. Beans and Peas are much more plentiful, and Marrows are available in fairly large quantities. Tenerife growers are

sending a good supply of Tomatoes; whilst Cucumbers, Seakale and Mushrooms are arriving from other sources in fairly large quantities. All ordinary vegetables in season are very plentiful, but root crops are getting scarcer.—E. H. R., *Covent Garden, April 1.*

REMARKS.—Trade is about the same as last week, and there is but little alteration in prices. Fewer consignments have arrived, and it is expected that stock in London will not be so large from now onwards.—Edward J. Newborn, *Covent Garden and St. Pancras, April 1.*

GARDENING APPOINTMENTS.

- Mr. Harry Edwards**, for 2½ years Gardener to Mrs. NORMAN CHRISTIE, Esdaile House, Hoddesdon, Hertfordshire, as Gardener to THOMAS CHATTO, Esq., Hillside, Elstree.
- Mr. W. Bowles**, for the past 16 months Gardener to HUGH GRAHAM, Esq., Offchurch, Bury, Leamington, previously for 2½ years Foreman at Park Hall, Oswestry, as Gardener to Captain HARCOURT WOOD, Caer Beris, Builth, Breconshire.
- Mr. H. Pryer**, for the past 5 years Gardener to H. F. STRAKER, Esq., as Gardener to W. RHODES, Esq., Gattou Cottage, Gattou, Reigate, Surrey. (Thanks for Is. for R.G.O.F. box.—Eds.)
- Mr. J. Taylor Diamond**, as Gardener and Land Steward to Colonel O. S. NUGENT, Farrer Connell, Mount Nugent, Co. Cavan, Ireland.
- Mr. W. A. Hurst**, for nearly 9 years in the service of HERBERT HICKS, Esq., Branwoods, Great Baddow, Chelmsford, as Gardener to HOWSON F. DEVETT, Esq., Frettons Danbury, Chelmsford.
- Mr. W. G. Warner**, Gardener to Captain ST. QUINTIN, Clifton House, Biggleswade, as Gardener to Captain G. E. TRYON, M.P., The Manor House, Great Durnford, near Salisbury, Wiltshire.
- Mr. G. Braddy**, General Foreman at the R.H.S. Gardens, Wisley, and previously employed at Eastwell Park, Ashford, Kent, as Horticultural Instructor to the Kensington and Chelsea Cottage Homes at Banstead, Surrey.
- Mr. J. Marshall**, for the past 2½ years at the R.H.S. Gardens, Wisley, as Gardener to F. NEWDEGATE, Esq., Arbury, Nuneaton.
- Mr. J. Ingall**, for 2 years Foreman at Rampton Manor, Lincoln, as Gardener to E. E. HARCOURT-VERNON, Esq., Grove Hall, Retford.

vancement of physical science, Professor Poynting took an active and distinguished part in the civic life of Birmingham. He was a Justice of the Peace, served on the Licensing Committee, and was for some years Chairman of the Birmingham Botanical and Horticultural Society and of the Botanical Gardens Committee.

A SLUG AND ITS PREY: E. Lazenby. The specimen sent for identification is not an insect but one of the carnivorous land slugs, *Testacella haliotidea*. It is generally believed that these slugs feed exclusively on earth worms, and your capture of the creature with its prey confirms this. *Testacella* is not injurious to plant life.

APPLE DISEASED: A. W. The insects on the Apple shoot are those of a beetle-mite (*Oribata*), and are harmless.

BULBS AFTER FLOWERING: F. H. Roman Hyacinths are practically worthless after they have flowered. But other kinds, whether forced or grown in beds, are useful afterwards for supplying cut flowers if the bulbs are properly ripened and planted out-of-doors in a sunny position.

CARDOONS: H. B. This vegetable should be grown in trenches, prepared much in the same manner as those for Celery, in March or early April. The trench should be 2 feet deep and 2 feet wide, and filled with farmyard manure, adding 3 inches of soil. Do not sow the seed before the first week in May, sowing two or three seeds in patches at about 20 inches apart, and thinning the plants to one at each station. An abundance of moisture should be afforded when the plants are growing actively, and the roots should be fed liberally with dilute liquid manure. To ensure well-blanching specimens the stems should be covered for eight or ten weeks, at first with brown paper, afterwards excluding the light by the use of long boards. The blanching should be done by degrees, banking up with soil as the work proceeds.

CHRYSANTHEMUMS: J. F. S. No disease is present on the plants. The injury is due to unsuitable soil or wrong cultural treatment in some other respect.

FAILURE WITH BULBS: A. P. For some reason which is not perfectly understood bulbs in certain seasons fail to flower satisfactorily, and you will see on reference to pages 175 and 207 that others have experienced the same trouble as yourself this year. The explanation is probably found in the bulbs not ripening properly the previous season. Local conditions may account for this, and as you purchased your stock from Holland only those on the spot could form a correct estimate as to the cause. A wet summer favours leaf-development late in the season, directing the energies of the plant in this direction, whereas a dry season results in the development and ripening of the flower-buds. Solid, well-ripened bulbs of a medium size always give better results than larger ones with loose scales.

GOOSEBERRY SHOOTS: J. C. Gooseberry mildew is not present. The injury has been caused by green fly when the shoots were young.

GRAFTING RHODODENDRONS: J. B. Rhododendrons are grafted on seedling stocks of *R. ponticum*, with stems about the thickness of a lead-pencil. The stocks are potted in October and grown in a cold pit or house until December, when they are brought into a warmer house, where there is a certain amount of bottom heat. As soon as root-action has started the plants may be grafted. This is usually done by saddle-grafting, or side-grafting. In saddle-grafting the top of the stock is cut off about two inches above the pot, and the stump trimmed up each side to roughly form an inverted V, taking care to make clean cuts. The graft should be of the previous sea-

Obituary.

PROFESSOR POYNTING, F.R.S.—The news of the death of John Henry Poynting, Professor of Physics in the University of Birmingham, will be learned with sorrow by large numbers of his pupils and colleagues in the scientific world. Beside rendering eminent services to the ad-

son's growth, of the same thickness as the stock, and three inches or so in length. It should have a piece cut from its base to fit on the stock, and be tied firmly thereto, care being taken that the edges of both stock and scion unite. In side-grafting the stock is not cut back, but a portion about one inch long is cut from the side, and the graft is cut to fit. Either method is equally good, but saddle-grafting is perhaps the easier and simpler after a little practice. The grafted plants should be stood in a close propagating case, with a temperature of about 65°. Union takes place in from two to four weeks, after which the young plants should be gradually hardened and grown in cold pits until the end of May, when they can be planted in the open.

HORTICULTURAL FUEL: C., Maidstone. If only ordinary greenhouse plants, which succeed in a minimum temperature of 50°, are grown, coke (if obtainable close at home) is slightly cheaper than coal, but the furnaces require more attention during the twenty-four hours than when anthracite coal is used. In the case of forcing houses, in which a minimum night temperature of from 65° to 70° is maintained, the fires need to be made up with anthracite (large lumps) at 9.30 or 10 o'clock at night, and the water is on the boil at 6 o'clock the following morning. In order to do this with coke the fires would require attention every three or four hours during very cold weather, so that what is gained on the price of coke, as compared with the price of anthracite, is lost on the extra labour incurred in stoking.

LABELLING PLANTS: Foreman. The object of labelling a plant is to enable its identity to be readily determined, and the label should, therefore, be fixed where it can be read most easily. In labelling plants in rows the tally may be either in front of the first or behind the last specimen of the particular variety; it matters but little which method is adopted, and there is certainly no rule in the matter.

LIGHT SOIL ON GRAVEL: T. D. S. Deep digging will be beneficial provided you incorporate with the soil plenty of material that will assist in retaining moisture and plant food. Animal manure of all kinds, and especially cow dung, will assist in this direction, also leaf-mould, decayed vegetable matter, or any other form of humus.

MELON CULTURE: W. B. Having raised the young plants singly in 3-inch pots and grown them on in a position near to the roof-glass, shift them into well-drained 6-inch pots before the roots become pot-bound. The soil should consist of four parts loamy soil and one part horse droppings or short manure, quite free from worms. Let the materials be slightly warmed before being brought into contact with the roots. Make the soil moderately firm about the roots, and return the plants to their former position near the roof-glass and water to settle the soil. Place a short stick to each plant for support after they have made a few inches of growth. When the plants have attained to a height of about 15 inches they should be set in mounds of soil. These should be formed at intervals of 2 feet; if the soil is placed on the floor of the house close to the hot-water pipes, or on the stage over same, spread about one peck of short manure in each of the positions where the mounds are arranged. Set the plants there in the same depth as in the pots, making the soil quite firm, afterwards watering with tepid water to settle the soil. Do not stop the plants before they have reached the height limit of the trellis. In the meantime laterals will push forth regularly from either side of the stems. Train these to the trellis at right angles as they develop. Pollination may be carried out in the following manner:—When a sufficient number of female (large) flowers are open pretty regularly over the individual plants, insert, when the pollen is dry, one of the smaller flowers in each expanded large flower, after divesting the former of its petals, and let it remain therein. Stop the fruit-bearing shoots at two joints beyond the fruit. Remove the first fruits from the bottom laterals to in-

sure a regular crop on each plant. When it is seen which fruits it is best to leave, remove the others. Five to seven fruits, according to the size and strength of the individual plants and the size to which the fruits of the variety grown are known to attain, will be a fair crop for each plant to carry. All superfluous fruits should be removed as soon as they show. When the roots push through the billocks or mounds top-dress them with a couple of inches thick of the same kind of compost as described above, and continue to apply such top-dressings as required until the intervening spaces are filled nearly level with the summit of the billocks. Sub-laterals and all unnecessary growths should be pinched out as they appear to prevent crowding of the shoots. The soil in which the plants are growing must be kept uniformly moist during the whole period of the plant's growth. When the fruits are swelling plenty of tepid water should be distributed over the plants and in the house generally at closing time on bright afternoons. An atmospheric minimum temperature of from 65° to 70° at night, and 5° higher by daytime with artificial heat should be aimed at running up the temperature 10° or 15° with sun heat. A little fresh air should be admitted to the house sometimes, increasing or decreasing the amount given according to the rise or fall of the thermometer. Run the temperature up to 95° or 100° at closing time in the afternoon, with a free distribution of moisture in the house at the same time when the fruit is swelling. Plenty of water should be distributed during the heat of the day in order to maintain a moist atmosphere. When the fruit is approaching maturity maintain a drier atmosphere in order to enhance the flavour of the Melons.

MELON LEAVES: E. W. R. We can trace no disease nor discover any cause for the unsatisfactory condition of the plants.

NAMES OF PLANTS: D. R. Shenstone. 1, *Alonsoa incisifolia*; 2, *Stenotaphrum americanum variegatum*; 3, Probably a species of *Cordylina*: a single leaf is insufficient for determining the name.—*J. H. A.* *Skimmia japonica* (male plant).—*H. P.* 1, *Prunus cerasifera*; 2, *Cupressus pisifera squarrosa* (often called *Retinospora squarrosa*).—*P. B.* 1 and 2, *Eria bractescens*, the latter of the form figured in *Bot. Mag.* t. 4, 163 as *Eria Dillwynii*.—*J. C., Constant Reader.* *Brunfelsia calycina* (Franciscana). Your other query was answered in the last issue, p. 228.—*W. B., Clare.* 1, *Polypodium aureum* var. *glaucum*; 2, *Onychium japonicum*.—*Isis.* 1, *Ornithogalum nutans*; 2, *Iris japonica* (fimbriata). A difficult species to cultivate in the open garden, but it will grow in very favourable situations.—*E. E. S.* A very promising seedling of *Odontoglossum crispum*. It should develop into a fine form.—*Mrs. J. H.* 1, *Asplenium Trichomanes*; 2, *Sedum Aere*; 3, 4, and 5, It is impossible to identify such dried up scraps without flowers; 6, *Cardamine hirsuta*.

NECTARINE LORD NAPIER: The injury is not due to a fungus. Branches of Nectarines are liable to die without any apparent cause.

PEACH SHOOT UNHEALTHY: D. R., Shenstone. The trouble is due to gumming. Sprinkle table salt on the soil as far as the roots extend in small quantities at intervals, using 4 lbs. of salt for one tree during the year.

POTATOS: Beginner. No disease is present in the tubers. The scab has been caused by injuries from the soil when the tubers were young.

PUBLIC SQUARES AND OPEN SPACES IN LONDON: J. W. The majority of public spaces and squares in London are under the control of the London County Council, and application for appointments should be addressed to the chief office, 11, Regent Street, London. A few are managed by the local public authorities, and some are private property. Apply to the Metropolitan Public Gardens Association, 83, Lancaster Gate, London, for a list of addresses.

RHODODENDRON LEAVES: Rhodo. The leaves have been injured by aphides when quite young. Spray with an insecticide.

RUNNER BEANS: Sherwood. For ordinary purposes it may not be necessary to employ such a large quantity of manure, but plants grown for supplying Beans for exhibition would benefit from the liberal dressing. The Climbing Bean is a gross feeder and repays for a generous treatment in the matter of manuring.

SALVIA SCLAREA: Perplexed. This beautiful Sage is a hardy perennial, but success is best assured by sowing a few seeds, which are freely produced, each summer. Plants thus raised will flower the following year, as in the case of hardy biennials.

SOFT SOAP FOR WASHING FLOWER POTS: F. A. E. We do not consider that the use of soft soap in cleansing flower pots would have the effect of rendering the receptacles less porous, but there is no need to use it for the purpose. If the pots are soaked in water a scrubbing brush will soon remove the dirt and other foreign matter.

TOMATOS: C. O. The disease is quite common, but the cause is not known, beyond that it is not due to a fungus. Such plants are never satisfactory, and the wisest course is to destroy them.—*Novo Castro.* The plant is not suffering from disease. Watering with a solution of potash, 1 oz. in one gallon of water, twice at intervals of a week would be beneficial.

VINES: Foliage. In the case of a viney with very large panes of glass and a south aspect, it may be advisable to use a little shading for three or four hours on hot summer days, such as is afforded by a herring net or something very light, merely to break the sun's rays. A coat of whitening or other permanent shading is objectionable, for vine leaves require plenty of sunlight. A maximum shade temperature of 90° to 95° will do no harm, excepting when the fruit is stoning, at which stage 10° lower is advisable. The leaves should not be close to the glass, and if your trellis is nearer than 2 feet the rods might be slung on wire hooks, which would make it easier to tie the shoots down. You should be careful to ventilate in the morning before the temperature rises much, and do not be afraid to open the lower ventilators and the door on hot, still days. Always anticipate a rising temperature, for the warmth of the atmosphere should never be lowered by ventilation.—*Singlehanded.* It will be advisable to train up young rods between the old ones with very long spurs if there is sufficient light for the young shoots, otherwise it will be useless to attempt it. Pigeon manure is a very powerful stimulant, and should not be applied in larger quantities than 28lb. to the perch for vines, and half that quantity for Peaches. The best way to use it is to dry it in an open shed, reduce it to powder, and apply in autumn or winter, but it may be applied now at half the strength stated. As you can obtain, free of cost, plenty of stable manure, bone meal, and wood ashes, you can do very well without a concentrated mixed manure, but you might apply a little quick acting stimulant, just before the flowers expand, such as nitrate of soda or ground saltpetre (nitrate of potash) 1lb. to the perch, and water it in. Wood ash and bone meal are both excellent plant foods, but rather slow in action, and may be applied liberally at any time. In a hot summer a light covering of partially decayed stable manure will be advantageous, but should not be applied before the border has become warmed by the sun.

VIOLETS MARIE LOUISE: H. J. P. and A. W. Violet leaf-blotch is present. Spray the plants with a solution of liver of sulphur, 1 oz. in four gallons of water. Be careful to wet the under sides of the leaves and drench the soil with the liquid.

SOME RECENT EXPERIMENTS IN THE APPLICATION OF ELECTRICITY TO PLANT PRODUCTION.

IT is desirable to make clear the scope of this article at the outset. There are many ways in which electricity may serve agriculture and horticulture in the future. Here it is only intended to discuss its possible direct application to increase or accelerate the production of a crop by modifying the electrical conditions under which that crop is normally grown. This is an application of electricity which is still in an experimental stage, but a brief description of the progress recently made will show that the next few years may enable a definite verdict to be pronounced as to its commercial practicability.

It is now a very long time since the first experiments upon this problem, modern though it seems to be. Perhaps some day it may be desirable to write the history of the investigation, but at the moment I think we may leave this pioneer work upon one side. As I shall hope to show later, the result of recent practical trials of this treatment has been to demonstrate that the significance of many of the statements of the earlier workers will have to be reconsidered. This is not the occasion for such a critical historical survey, so leaving aside this earlier work, which makes a fascinating chapter in the history of science, we will proceed at once to a discussion of the

modern methods of applying electricity to plant growth.*

At the present time in nearly all the large scale trials the electricity is applied as a discharge into the atmosphere above the plants. This simply modifies the electrical charge which is already reaching the plants from this source. Usually the air above the growing plant is charged to a positive potential. This charge is continually leaking away through the plants to the ground, and is continually renewed from the upper layers of the atmosphere. It is extremely variable, but in normal weather is comparatively small, not more than a few hundred volts at a point about a yard above the plant. But in thunder weather, when the electrical charge increases, the potential is greatly increased and the current leaks away more rapidly to the ground.

Now the method of electrical discharge

the supply of electricity to quite large areas.

The greatest practical difficulty on the electrical side is the adequate insulation of the system of wires which are kept at such a high electric potential. This is a very necessary precaution to ensure that the current shall be leaking away off the thin wire stretched above the crops at intervals of about ten to fifteen feet, rather than elsewhere. These difficulties have been overcome to an extent that shows that the electrical problems in the way of practical application of the discharge can be solved.† We may now, therefore, turn our attention to the experiments devised to ascertain whether such practical application would be advantageous.

The investigator who wants to apply electricity in the field is confronted with one great difficulty. He has no adequate knowledge of the scientific side of the

FIG. 107.—ELECTRIFIED AREA, DUMFRIES, 1913. LARCH POLES WITH INSULATORS SEEN IN THE CENTRE: THESE CARRY CHARGED OVERHEAD WIRES. ON RIGHT, WIRE NETTING ERECTED IN ORDER TO SCREEN THE CONTROL AREA.

employed in these experiments generates a very high potential of electricity by means of a coil and a series of rectifying valves, and then charges a system of thin wires spread above the plants at intervals of ten to fifteen feet, to this high potential of some 50,000 to 100,000 volts. The wires are so highly charged that though raised upon Larch poles to a height of from ten to fifteen feet above the plant (fig. 1), they continue to discharge sufficient electricity into the air to raise the electric current passing from the air to the plant to about ten thousand times its normal value.

The electrical apparatus for developing these high-tension currents has been designed by Mr. J. E. Newman, with the advice and help of Sir Oliver Lodge, and it can easily be rendered efficacious for

problem upon which to base his plan of treatment. Laboratory investigations are now in progress which may in time settle the broad principles of treatment, but the effect of the practical application of the discharge upon a large scale had to be demonstrated before it was realised that these problems called for solution. At present the times of applying the discharge, the strength used, the duration of discharge, are all matters that have to be decided empirically. The final answer to the practical problems involved will only be obtained when the practical control of the field experiment is based upon principles thought out and thoroughly tested by previous work in the laboratory. With the aid of a grant from the Development Fund, administered through the Board of

* Brief reference to these earlier experiments will be found in other papers. See, for instance, *Journal of the Board of Agriculture*, Vol. xvii., p. 14, and Vol. xx., p. 582; also *Journal of the Royal Horticultural Society*, Vol. xxxvii., p. 15.

† See the papers previously mentioned for further detail as to apparatus, also E. C. Dudgeon, "Growing Crops and Plants by Electricity."

Agriculture, these problems are now being attacked in the laboratory at the University of Leeds. Some points have been cleared up, but there is still a great deal of work to be done, and until it has been done a general discussion of principles is premature.

In the meantime, large-scale field trials have also been in progress, carried out in part by the University of Leeds, and also through the energy and interest of private individuals, especially of Miss E. C. Dudgeon at Lincluden, Dumfries, Mr. William Low at Balmakewan, near Montrose, and Mr. Raymond Bomford at Salford Priors,

strength of the electrical discharge distributed over the plants. It was obviously no use to weigh crops from experimental and control areas with great care, unless these figures could be contrasted with significant figures as to the electrical comparison between the two areas. To take an extreme case, an increased yield of 50 per cent. would be of but little help to the experimenter unless it could be ascertained what were the actual electrical conditions accompanying this increased yield. An attempt to repeat this result might be made with different electrical quantities and an entirely different yield obtained.

in which the new facts learnt about the distribution of the discharge entirely alter the conclusions that might at first sight be drawn from it. It should first be stated that on a windy day the discharge does not spread equally on all sides of the electrified area. It is carried by the electrically charged particles of the air, and, therefore, of course, spreads very little against the wind, and a very long way in the direction of the wind. In the light of this knowledge let us discuss the field experiment carried out at Dumfries in 1912.

This experiment was made upon Potatoes (British Queen), and it was arranged that the crop should be lifted and weighed in tenth-acre plots from the whole of the electrical and control areas.

As these two areas totalled four acres of ground, this provided that any errors due to other local conditions, such as soil conditions, could be gauged very accurately. This experiment was carried out in complete ignorance of the facts about the distribution of the discharge stated above, and the experimental area was arranged as shown in the accompanying diagram (fig. 109). The idea in so distributing electrified and control areas was, of course, to equalise as far as possible differences in soil and exposure between the different ends of the field.

When the crop was lifted and weighed it was found that practically no difference existed be-

FIG. 108.—HIGH TENSION DISCHARGE APPARATUS AT DUMFRIES.

near Evesham. These field trials have lately entered upon a new phase, and the most useful purpose this article can serve will be to bring out this point of view and discuss its reference to the practical problems involved.

When funds were available for making large-scale experiments at the University Experiment Farm at Garforth, it was immediately decided to direct attention in the first place to the methods of measuring the actual

* See, for instance, Priestley and Knight, "The Toxic Action of Electric Discharge on *Bacillus Coli*," *Proc. Roy. Soc.*, and Knight and Priestley: "The Respiration of Plants under Various Electrical Conditions," *Annals of Botany*, 25, p. 135.

It took some time to devise suitable methods for measuring these electrical conditions, but the difficulties, which were considerable, were eventually overcome, and a paper will shortly be published elsewhere describing these methods and drawing certain conclusions from their use up to the present. One of these results is of very great significance. It has been demonstrated beyond doubt that the effect of the electrical discharge is by no means confined to the area directly beneath the wires. It will be seen how seriously this conclusion affects all the field trials made up to the present. Perhaps this may be made clear by reference to a specific experiment,

FIG. 109.—ELECTRIFIED AND CONTROL AREAS.

tween the yield from the electrified and control areas. At first sight this seemed a decisive proof that the electrical treatment had no practical value; the conditions for growing were good, and the crop on the light soil was excellent, averaging 14 tons to the acre. But concurrently with these experiments the measurements at Garforth were in progress, and by the time the Potatoes were weighed the data to hand from these measurements led us to anticipate that the crop should in any case give a nearly even yield. These measurements had shown the effect of wind in carrying the discharge. Now a little consideration of the arrangement of the plots will show that, in whatever direction the wind might blow, it always carried the charge from an electrified to a control area. Very light winds will carry the discharge the full length of the control areas in these experiments, so that the electrical difference between these four areas was negligible. By our very precautions we were undone, and the results of the year's trials are without significance. This example will suffice to show that experiments in which weight of crop alone are taken cannot be relied upon: they must be accompanied by figures expressing the electrical comparisons between the two experimental areas. In the light of these facts it would be interesting to review the earlier experiments.

Space will not permit a full discussion, but the two following points may be emphasised. Firstly, the validity of the results obtained with the system of electrical treatment will be greater as the size of the control area increases; secondly, the results will also be more reliable when the discharge wires are nearer to the ground, as this means less spreading of the discharge in the wind.

It should be pointed out that these new facts

as to the distribution of the discharge do not point to any impossibility in its practical application; rather the reverse, as they show how easy it will be to arrange for the discharge to cover a considerable area.

But they have considerably increased the difficulties in the way of carrying out crucial experiments which shall finally decide the question as to whether the discharge will produce a sufficiently increased crop to justify its application upon a large scale. To decide this point experiments must be carried out in which the weight of crop obtained under measured electrical conditions is compared with the weight of a crop from a genuine control area in which the electrical conditions approach closely to those under a normal atmosphere. The rest of this paper will describe the progress that has been made in obtaining this quantitative comparison between known electrical conditions and a genuine control area.

For this purpose it was necessary to standardise the methods of electrical measurement, so that they could be used in all field experiments. These measurements can now be carried out by convenient portable instruments with considerable ease, and will give a very fair representation of the electrical conditions of different points within an area. In subsequent years it is hoped that in all the large-scale experiments in Great Britain these measurements will be made so that the value of any difference in yields may be assessed in the light of valid electrical data. *J. H. Priestley.*

(To be concluded.)

ORCHID NOTES AND CLEANINGS.

LAELIO-CATTLEYA CORNELIENSIS.

THIS very delicately-coloured hybrid was raised by Mr. H. Chandler, Orchid-grower to the Earl of Craven, Coombe Abbey, Coventry, who for the second time kindly sends a flower of it, the present bloom being the lighter-coloured of the two, and more nearly resembling *Cattleya Schröderae*, which, with *Laelio-Cattleya luminosa*, produced it. The flower is as large as *C. Schröderae*, but rather thinner in substance. The sepals are nankeen-yellow, the petals blush-white, with a nankeen-yellow shade; lip broad, rose-coloured at the base, with yellow lines, the disc being orange-coloured shading to light yellow, the crimped front tinged with pink.

The lip of the variety previously seen was rose-purple, with an orange-yellow disc.

BRASSO-LAELIO-CATTLEYA AUREOLE.

THREE flowers of this pretty hybrid, between *Brasso-Laelia Mrs. Gratrix* (*B. Digbyana* × *L. cinnabarina*) and *Laelio-Cattleya luminosa* (*C. Dowiana aurea* × *L. tenebrosa*), are sent by Mr. F. C. Puddle, gr. to W. H. St. Quintin, Esq., Scampston Hall, Yorkshire. In colour and form they are nearest to *B.-L. Mrs. Gratrix*, and, although they vary in shape and tint, the dark colour of the lip of *L.-C. luminosa* is almost entirely suppressed. The form of the labellum differs in each flower, one having a distinctly trilobed arrangement, while in the other two the separation of the side and front lobes is not clearly defined. The flowers are 6 inches across, pale yellow more or less tinged and veined with copper-red, the slightly fringed labellums being veined with rose colour.

DENDROBIUM SUPERBUM HUTTONII SOUTHFIELD VARIETY.

OUR illustration (fig. 110) represents this rare *Dendrobium*, for which W. Waters Butler, Esq., Southfield, Edgbaston, Birmingham (gr. Mr. Jones), received the R.H.S. Award of Merit on the 24th ult. *Dendrobium superbum*, of the typical form collected in the Philippine Isles, has

rose-coloured flowers with claret base to the lip. It is often grown in gardens as *D. macrophyllum giganteum*, and the small-flowered variety as *D. anosmum*. Three white-petalled forms are known—viz., *Burke's* variety, white with pale-purple colour at the base of the lip; *Dearei*, which is wholly white; and *Huttonii*, in which the basilar part of the lip is dark violet, a character which is exhibited in the highest degree in the *Southfield* variety. The flowers have all, in greater or lesser degree, the odour of medicinal Rhubarb, the type being very strong, but the variety *Huttonii* only pleasantly so. The section is widely distributed in the Malay region, and all forms require the warm-house treatment.

THE ROSARY.

WANTED, A REAL YELLOW CLIMBING ROSE.

ALTHOUGH there is a great wealth of climbing Roses, a real yellow variety is lacking. We have many free-growing sorts with yellow shades of colour, but unfortunately those with the most yellow are not free-flowering, if I except *Aglaia*, which is without doubt still the best in its section. Many fail to flower this Rose early, or well, owing to mismanagement in pruning. The plant requires time to become established, and

[Photograph by R. A. Malby.]

FIG. 110.—DENDROBIUM SUPERBUM HUTTONII "SOUTHFIELD VARIETY."

CIRRHOPE TALUM TRIMENII.

FOR the second time this rare species has flowered with the Hon. N. Charles Rothschild.

It is a dwarf, evergreen species, with slender scapes about 3 inches high, bearing at the apex a tuft of seven to nine flowers, arranged in a very short raceme; they are yellowish-white with purple spotting on the back of the dorsal sepal. The lip is primrose-yellow with a few rose-coloured dots at the base. *Cirrhopetalum* is merged into *Bulbophyllum* by many authors, and this species belongs to the section which is not distinguishable from *Bulbophyllum* by the characters assigned to *Cirrhopetalum*. It was imported from Ceylon, and is described in *Trimen's Handbook of the Flora of Ceylon*,

then the only things needed to assure an annual full crop of its pale yellow flowers are vigorous shoots which should be retained at pruning time their whole length, removing all weakly ones and any that flowered the previous season. The pruning should be done directly the flowering season is over, so that the shoots retained for furnishing next year's crop will have ample time to become matured. By a climbing Rose I mean one that will make shoots 12 feet long in a season and produce flowers almost the whole length of the shoot in the same manner as *Excelsa*, *American Pillar* and the bulk of those belonging to the *Wichuriana* section, but varieties like *Allister Stella Gay* or *Ther*, which are but semi-climbers, although free-flowering.

The so-called yellows—such as Aviateur Blériot, François Guillot, Goldfinch, Klondyke and Shower of Gold, are either not good in colour or too sparse of flower. We need a yellow flower of the shade of Perle des Jardins with the freedom and habit of Dorothy Perkins. *E. M.*

NEW ROSES AT BAGATELLE.

A TRIAL of Rose novelties will take place as usual at Bagatelle in 1914-15. New Roses are sent to the authorities with the name of the raiser plainly attached thereto. So far as possible the plants should have been raised in pots, and at least five specimens should be sent to the "Conservateur des Promenades de Paris, Roseraie de Bagatelle, au Bois de Boulogne, En gare de Neuilly-Porte-Maillot-Paris," before April 15. A note of any special treatment required must be attached. They will be put in the ground immediately on reaching Bagatelle, and will remain there until October, 1915, so that the jury can observe their flowering and habit during two seasons. The following are some particulars of former awards:—

1907.

Bagatelle Gold Medal.—Marquise de Sinéty, Pernet-Ducher (Lyon).

Classed Roses.—Mme. Edmond Sablayrolles, Bonnaire (Lyon); Mme. Constant Soupert, Soupert et Notting (Luxembourg); Mrs. Peter Blair, Dickson and Sons.

1908.

Bagatelle Gold Medal.—Rhea Reid, E. G. Hill (Richmond, U.S.A.).

Bronze Medal of the Ministry of Agriculture.—Dorothy Page Roberts, Dickson and Sons.

Bronze Medal of the French Horticultural Society.—Mme. Ségond-Weber, Soupert et Notting (Luxembourg).

Bronze Medal of the Rose Section of the French Horticultural Society.—Mrs. Dudley Cross, W. Paul and Sons, Ltd.

Bronze Medal of the Society of Rose Lovers.—Frau Oberhofgärtner Singer, P. Lambert (Germany).

1909.

Bagatelle Gold Medal (French Roses).—Lyon Rose, Pernet-Ducher (Lyon).

Bagatelle Gold Medal (Foreign Roses).—Mme. Ségond-Weber, Soupert et Notting (Luxembourg).

1910.

Bagatelle First-class Certificate.—Molly Sharman Crawford, Alex. Dickson.

Bagatelle Certificate.—Mlle. Marie Mascuraud, Bernaix (Lyon); Lady Alice Stanley, MacGredy; Commandeur Jules Gravereaux, Croibier (Lyon).

1911.

Bagatelle Gold Medal (French Roses).—Beauté de Lyon, Pernet-Ducher (Lyon).

Bagatelle Gold Medal (Foreign Roses).—Jonkheer J. L. Mock, Leenders (Holland).

Bagatelle First-class Certificate.—Viscountess Enfield, Pernet-Ducher (Lyon).

Bagatelle Certificate.—May Miller, E. G. Hill (Richmond, U.S.A.); Walter Speed, Alex. Dickson; Désiré Bergera, Barbier et Cie. (Orléans).

1912.

Non-Competitive.—Rayon d'Or, Pernet-Ducher (Lyon); Sunburst, Pernet-Ducher (Lyon); Président Vignot, Pernet-Ducher (Lyon).

Bagatelle First-class Certificate.—Mme. Jules Bouché, Croibier (Lyon).

Bagatelle Certificate.—Frau Margrethe Moller, Poulsen (Copenhagen); Orléans Rose, Levavasseur (Orléans).

1913.

Bagatelle Gold Medal (French Roses).—Mme. Charles Lutaud, Pernet-Ducher (Lyon).

Bagatelle Gold Medal (Foreign Roses).—Mabel Drew, Alex. Dickson.

Non-Competitive.—Louise-Catherine Breslau, Pernet-Ducher (Lyon); Mme. Edmond Rostand, Pernet-Ducher (Lyon).

Bagatelle First-class Certificate.—Grange Colombe, Guillot (Lyon).

Bagatelle Certificate.—Mrs. Amy Hammond, MacGredy; Luise Lilia, Peter Lambert (Germany); Wichmoss, Barbier (Orléans).

THE HARDY FLOWER BORDER.

PERENNIAL ASTERS.

THE cultural requirements of these plants are very few, but a little attention to details is necessary to obtain the best results. February to early March is perhaps the best time for dividing and planting, and 4 feet each way proves a suitable distance for the more robust-growing varieties; the smaller sorts may be planted much closer, to form drifts, and do not require staking. Ten or twelve growths is sufficient to leave to each plant of the most vigorous, and about five Bamboo canes to each plant, well spread out and connected by a band of soft string, to which some of the growths may be tied, proves a neat way of staking, and encourages each growth to develop lateral flowering shoots almost to the base.

If inconvenient to dig the border when planting, a hole may be made, placing some short manure in and covering with a layer of soil previous to planting, after which operation the plants may be watered to settle the soil about the roots, and occasionally afterwards should the nature of the soil and weather conditions render it necessary. During the growing season an occasional sprinkling of some safe artificial manure will assist established plants, and frequent surface hoeings will prove beneficial.

Feltham Blue is a most desirable Aster, having large, distinct flowers, which last a long time in perfection. Other pleasing varieties are:—Ariadne, Beauty of Colwell, Celestial, cordifolia, Captivation, Coombe Fishacre, Chapmanii, Delight, Edwin Beckett, Freedom, Grace Darling, Hon. Edith Gibbs, Isabel, Ophir, St. Egwin, Trumpeter, Triumph and White Dinah. *C. Luxford, Walmsgate Gardens.*

MECONOPSIS CHELIDONIFOLIA.

THE Chinese and Himalayan Poppies are usually considered to be plants which are not too easy to grow, so that it is refreshing to find one that grows well and is a good perennial. The first time I saw *Meconopsis chelidoniifolia* was in the late Mr. Gambleton's garden, growing in ordinary soil on a border. Although not so striking or beautiful as the blue biennial Poppy, yet this newcomer is pretty and attractive. In 1912 it was 2 feet high, and last year it grew 4 feet when planted in a peaty soil. The stems are very slender, branching out freely at flowering time, in July, when the stems turn quite a deep brown or nearly black. The ovoid flower-buds are smooth, gracefully hanging on wire-like stems. The flowers are yellow, 1½ to 2 inches across, with crimped petals; the pods are hairless; the leaves are trilobed. Although rather similar to those of the Great Celandine, they are not so deeply lobed, and are less toothed. Another good point about *M. chelidoniifolia* is the freedom with which it may be increased. The roots divide easily in spring, and last year bulbils were produced on the flower-stems, which produced young plants. Wilson mentions this plant as occurring on the Lunggan-Sungpan highway in North-Western Szechuan, and the following paragraph from *A Naturalist in Western China*, Vol. I., p. 127, gives an idea of its associates in its own habitat:—"Tall-growing herbs made a grand display, especially the apetalous *Astilbe rivularis*, *Spiraea Aruncus*, *Anemone vitifolia*, with white and pink flowers like the Japanese *Anemone*, *Artemisia lactiflora*, with large panicles of milk-white fragrant flowers. Im-

patients, with yellow, pink and purple flowers. Mixed with them were also the Meadow Rue (*Thalictrum*), *Aconites*, many *Senecios*, and *Meconopsis chelidoniifolia*, growing about 3 feet tall, with clear yellow flowers, saucer-shaped, and 2½ inches across. Acres of the countryside are covered by these various herbs." *C. P. Ball.*

THE YORKSHIRE RHUBARB HARVEST.

More Rhubarb is grown within a radius of twenty miles of Leeds than upon any similar area in the world. Hundreds of acres, chiefly on the south, south-east, and south-west of the city, are devoted entirely to its production. The Rhubarb industry in West Yorkshire represents a total capital of somewhere between £300,000 and £400,000. Why should West Yorkshire have been singled out for this distinction? A complete response to this question is not always forthcoming. Beyond a doubt, there is something in the soil, the climate, and the cleverly-directed native energy in handling a crop of forced Rhubarb that make for success in Yorkshire Rhubarb cultivation. In the south and south-west of England many experts have tried their hands at Rhubarb forcing for a few seasons, and have failed to find profit therein. They are not nearly so much to blame as is the climate. Just at the time of the year when Rhubarb roots require extra moisture, Nature condemns them to suffer thirst like the flocks and herds around them.

The industry of forcing Rhubarb on a large scale in Yorkshire, or in any other shire for the matter of that, is a development that has happened in the lifetime of those who have made fortunes out of it. It is about fifty years old, and the last thirty years have witnessed its advance from the stage of doubtful experiment to that of full fruition. The process of Rhubarb growing is this:—In spring you plant out-of-doors and encourage with ordinary manure roots chiefly cut from stock that has helped, perhaps, to produce two or three generations of Rhubarb. These roots develop, and if you destine them for forcing purposes you do not pluck their annual harvest, but leave even the most flourishing crop to rot as it were. If you refrain from plucking or pulling a crop of natural Rhubarb the sap you would draw off goes back to the root. In Yorkshire crops of natural Rhubarb are not very extensively pulled. Scores, if not hundreds of acres of healthy-looking, vigorous Rhubarb are left untouched, though the sticks, reduced to pulp, help dyers of textile fabrics in operations too occult to be described here. The natural Rhubarb leaves soon decay and enrich the earth that bore them. The Rhubarb root that has been plucked whilst it should have been husbanding its energy does not in two or three years in a shed, even though helped most powerfully by artificial aid, answer expectations either as to quantity or quality of crop. Unplucked Rhubarb yields twice as much of the forced product as plucked.

Having gathered sap and strength out-of-doors for two years or more, the original roots are either ploughed or dug out and ranged in a forcing shed, in tightly-fitting rows, with a little earth dividing each row, with here and there a narrow path between the rows. Thenceforward to the time of harvest, which early in the year is in full swing, almost the only aids to growth are heat, moisture, and absence of light, natural or other. Darkness gives to the curly, crisp leaves the desired golden hue. The least ray of light turns the leaves green. An incandescent or acetylene lamp will spread mischief coterminous with the range of its beams. So there is ample scope for human agency in forcing the best marketable Rhubarb. "Supervision is an art or a science," says a Yorkshire grower who has sent more Rhubarb to southern markets, probably, than

any four other growers combined. "It does almost as much as Nature for Yorkshire Rhubarb." Men who want their Rhubarb early for the Christmas trade transplant the roots in November; but their prospects of a good crop are less than if they transferred those roots in the sheds late in December or early in January. Heat is supplied to the houses by hot-water pipes and flues. A first-rate crop occasionally hides every little gap left for the foot of the gardener, and presents a beautiful mass of red, amber, and gold, if there be light enough to see it.

The length to which a stick of Rhubarb is allowed to grow depends on the grower, his customer, and the state of the market. If you let it alone long enough some Rhubarb will ascend towards the ceiling of a 4 feet high house; but from 20 to 25 inches is tall enough for handling in English markets. If unrestricted, a stick may develop 1½ lb. or even 2 lbs. avoirdupois, but most of the crop is plucked when the sticks weigh from 2 ozs. to ¾ lb. or 1 lb. Forced Rhubarb is most palatable and tender if plucked exactly when it is ready. Some sticks are ripe at 3 ozs., and others not till they reach 1½ lbs. A skilful grower knows what is ready. Like Rosas and other flowers, it is a case with Rhubarb of pluck and come again; so there are many crops in a season. The early season starts about a fortnight before Christmas, and lasts till the middle of February or later, weather permitting. Spring weather, arriving unduly early, forces outdoor Rhubarb into life before the Rhubarb forcer desires, for it kills his trade. Though most English epicures prefer delicately-forced Rhubarb to its coarser natural congener, they take to the latter for a change immediately it is offered them, at least for a while; then, perhaps, they go back to the more dainty growth. The marketing qualities of good forced Rhubarb are: a stick of deep red, a crisp, curly, golden leaf, and a fresh, bright bloom upon both stick and top. The limpness that an alert customer quickly detects, especially late in the season, when freshness wears off sooner, spoils forced Rhubarb in six or twelve hours after plucking. Tied in bundles and packed in hampers or boxes containing from 10 to 30 dozen bundles each, Yorkshire Rhubarb is sent to every considerable centre of population in the kingdom, even to Devonshire, Cornwall, and along the south coast. When the Rhubarb harvest is at its busiest, hawkers buy cheaply much of the inferior qualities—hence the idea that the nearer you are to the Rhubarb beds the worse the Rhubarb offered you. But the shopkeepers of Leeds and Bradford, whose customers can afford to pay for it, insist on having some of the best stock grown. Three of the principal railways run quick Rhubarb specials from Leeds to London, distributing their freight as they go, as mail trains do. London is the best customer.

Rhubarb farms vary from three to a hundred acres, and provide work for men, women and boys, many of whom are rough gardeners and farm hands who, in the height of the Rhubarb season, might be short of other occupation. Twenty or thirty years ago nearly all the Rhubarb sent from the West Riding was sold on commission by agents in London and at other centres. Many of the middlemen have now been dispensed with, shopkeepers and wholesale merchants receiving their stock direct from the growers. Carriage is cheapened by consigning the produce in bulk, and the receiver of a big consignment makes most of his profit out of the difference in carriage. Rhubarb farmers say that since railway companies began to work hand-in-hand as to charges, in 1903, claims for damage have not been met so reasonably and transit has not been so careful. Crops being light this season, the price—1s. 3d. to 1s. 6d. a dozen bundles at the markets—is higher than usual. Scotchmen sometimes buy Yorkshire Rhubarb by weight.

The old roots, after harvest, are dug up, and

many of them perish from keen frosts; the survivors, after resting a year or two, are cut up into sections and planted again to renew the general stock. Large quantities of Rhubarb are grown naturally in Yorkshire, the total amount varying with the seasons. What is plucked is marketed from soon after Easter onwards. It is not sent far from the West Riding, as nearly every district in England can grow what it wants. As soon as growers in the warm latitudes of the south have outdoor Rhubarb ready, they rush it to market and substantially check the sale of the forced article. W. L.

NOTICES OF BOOKS.

LA TAILLE LORETTE.*

Nor many years ago the visitor to France found that pleasant country divided into two warring sections. The guilt or innocence of a hitherto unknown military officer was the cause of this division, and the cautious kept the inflammatory name unspoken.

In French pomological circles at the present time there also is a name which lovers of peace will studiously avoid. It is that of M. Louis Lorette, chief horticultural instructor at the school of Wagnonville, near Douai; and the cause of the discussion is a system of pruning which he advocates. Since the first detailed description which appeared in June, 1912, the resources of the French language in invective and satire have been put to fullest service, almost drowning the few small voices of appreciation which were raised in some quarters.

We now have the true and only authoritative message given us in book form by the author himself. As this pomological disturbance has not yet reached our shores, it may be of interest to state in a few words in what way this system of pruning differs from the established practice.

In the first place, it is an almost complete substitution of summer pruning for the more usual practice of winter pruning. Secondly, it relies on the development of the stipular buds rather than on the more prominent growth-buds.

The results are stated to be desirable in every way. Spurs are developed nearer the main branch; production is enormously increased; and lastly—a point by no means without importance—pruning is done under genial summer conditions.

Let us follow M. Lorette in pruning a cordon Pear tree, as an example. When planted early the one-year-old tree is pruned back one-quarter of its length. This will cause the side buds to shoot with varying vigour, the strongest being naturally at the top. The side buds, if examined carefully, will be found to possess stipular buds which do not in usual pruning develop. It is to these buds, however, that M. Lorette looks for the development of his future spurs. Instead of pruning the side shoots of the tree to three or four buds each, and after one year's growth making these the foundation of the spurs, he takes off the side shoots completely in June, and the tree will then push these stipular buds at the autumn growth, and they will form spurs. These spurs will therefore be close to the main branch and benefit by an increased food supply.

This is the basis of the system, and the growths from the spurs are treated in the same manner. When the leading shoot is cut in the following winter (this being the only winter pruning necessary), it is again a stipular bud which is made to supply the leading shoot.

By preventing the sap from passing upwards in the easiest manner, as through a terminal bud, the side spurs are greatly strengthened and their formation hastened.

* Par M. Louis Lorette. Versailles, 1913.

Whether the system is new, or whether it is only the old "taille à l'écu" revived, the fact remains that M. Lorette can show trees loaded with fruit, and the illustrations in the work before us show that formally trained trees can bear prodigious crops.

Such, then, is the system which is put forward by M. Lorette, and described in his book, somewhat circuitously it must be admitted. As to the work itself, it is illustrated by many photographs and cuts, but those not conversant with horticultural French will find themselves rather lost in a maze of "brindilles," "dards," "conrons," and similar formations. A good English translation would be of great interest, as pruners in this country make too little use of the refinements of the art.

It must be confessed that the padding, which is somewhat lavishly used in this work, is hardly worthy of its subject. Calendars of operations and such information as that "nurserymen may be found in the suburbs of all towns, and they graft, form and sell trees," seems scarcely needed in the twentieth century. E. A. Bunyard.

PLANT NOTES.

PSYCHOTRIA JASMINIFLORA.

According to Nicholson's *Dictionary of Gardening*, the genus *Psychotria* consists of about 500 species, yet very few of them are in cultivation. From a floral point of view, the finest of them all is *P. jasminiflora* (figured in *Gard. Chron.*, August 16, 1879), which thrives in an ordinary stove temperature. It forms a neat-growing evergreen shrub, clothed with ovate leaves, about 3 inches in length, light-green and glabrous above, and glaucous underneath. The flowers, which are disposed in compact terminal panicles, are in shape very suggestive of those of a *Bouvardia*, but in the *Psychotria* the clusters of blossoms are partially drooping. A notable feature is their intense whiteness, in which respect there are very few flowers to equal them. The cultural requirements of this *Psychotria* are much like those of the *Ixoras*—that is to say, cuttings of the half-ripened shoots inserted in a sandy compost and placed in a close propagating case where there is a gentle bottom heat, will strike root without difficulty. A suitable compost for established plants is a mixture of loam, peat and sand. While this *Psychotria* is remarkable for the beauty of its blossoms a second species, *P. cyanococca*, is noteworthy for its profusion of bright-blue berries, the blossoms being insignificant. Introduced from Nicaragua by the late Mr. William Bull, of Chelsea, about forty years ago, this was for a time fairly popular, but it now appears to have almost dropped out of cultivation, though its name still occurs in the *Kew Hand List*. It is of soft growth, with hairy leaves, and forms an upright-growing plant. The berries, about the size of Peas, are of a bright-blue colour. Seedlings are very readily raised. W. T.

FOREIGN CORRESPONDENCE.

"A NEW SOURCE OF OAK TIMBER."

A CABINETMAKER to whom I communicated the information given by Mr. Jackson on p. 188, under the above heading, informed me that the mere fact of such timber having been discovered in the position indicated is not incredible, but he expressed some doubt on the enormous quantities stated to exist. The man told me that near Rosenheim, at the Austro-Bavarian frontier, there is embedded in the river Inn "a whole forest of oak timber," which cannot be made use of only on account of the inaccessibility of the place, but it would only require a road to be built to make the carrying of the logs to rail practicable. E. Heinrich, *Plonegg (Bavaria)*.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

SEED-SOWING IN THE COOLER HOUSES.—The seed-vessels of *Odontoglossum* and allied Orchids are ripening fast. As soon as the pods show signs of bursting tie a piece of tissue paper around them to prevent the seeds from dropping to the ground. Tear a small opening in the top of the paper to admit the air, as close conditions might set up damping and cause the seed pods to decay. As recommended on page 22, *Odontoglossum* seeds should be sown on the tops of pots containing plants of their kind, and preferably growing seedlings, but the compost must be in good condition. Seeds, even from the same pod, do not all germinate at the same time; sometimes it is a very long time before the seedlings appear, therefore the soil should be such as will remain sweet for at least a year. Before sowing the seed on the pots, cut away all growing moss and remove lichens and other foreign growths, as these might smother the seedling Orchids. Water the compost a few hours before the sowing is done, so that the seed will adhere readily to the soil and distribute the seed evenly over the surface. The after-treatment consists in never permitting the seed to become dry, taking especial care in this matter when the weather is bright and the atmosphere dry. If only a few pots are sown, dipping the receptacles in water is the best means of keeping the surface moist, and this will obviate all danger of washing the seeds out of position by the water-can. But where large numbers of seedlings are raised this method is not practicable and a reliable sprayer must be brought into use. The greatest pest of Orchid seedlings is a miniature black fly, almost as small as a gnat. The insects lay their eggs in almost any new potting compost, and the maggots that hatch out attack not only the materials of the potting compost, but even the seedlings, usually at the base. I know of no certain method of combating this pest, but fumigations on frequent occasions will destroy the mature insects when in flight. It will be well also to spray with some safe insecticide. Seedlings raised from seed sown in the autumn are sufficiently large for pricking out into store-pots. Several seedlings may be placed together in receptacles 2½ inches to 3 inches wide. Do not neglect to shade the plants when the sun is shining brightly, and spray them overhead whenever the conditions are favourable, for overhead sprayings are beneficial to all *Odontoglossums* in their early stages of growth.

REPOTTING.—Plants sufficiently far advanced in growth that require more root-room should be repotted, and if the work is done now, the plants will become established before the hot summer weather sets in. When the seedlings have developed their fourth leaf, the roots need ample room for development. Fill the pots to about one-third their depth with chopped roots of bracken Fern to provide suitable drainage. The compost may consist of equal parts of broken peat, broken Oak leaves, and chopped Sphagnum-moss, lightened with plenty of sand. Make the compost moderately firm about the roots.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

HARDY BAMBOOS.—Now is a suitable time to divide and make fresh plantations of these charming evergreens. They may be planted in groups at a curve in a drive, on the slopes of a ravine, or on the banks of a pond or stream. In autumn and winter, when many other woody plants are bare of foliage, the greenery of Bamboos and their graceful habits provide a great charm in the garden. The sites for planting should be sheltered from cold winds, and partially shaded. The plants, however, will thrive

in full sunshine if the soil is loamy, and not liable to become baked up in summer. Strong, loamy soil, trenched 2 feet deep, and enriched at the bottom with well-rotted manure, is suitable for all the members of the Bamboo family. Plant in holes some 4 to 6 feet in diameter, and afford the roots an annual mulching of well-decomposed animal manure for the first three years afterwards. Given this treatment the culms will grow from 6 to 12 feet in height, and the plants make very ornamental specimens. *Phyllostachys nigra*, *P. Castillonis*, *P. flexuosa*, *P. Henonis*, *P. mitis*, *P. violescens*, *P. viridi-glaucescens*, *Bambusa fastuosa*, *B. quadrangularis*, *B. palmata*, *Arundinaria nitida*, *A. Metake*, *A. Simonii*, *A. nobilis*, and *A. Falconeri* are all splendid plants. The last is a little tender in low-lying, humid districts.

SAXIFRAGA PELTATA.—This is a favourite subject for growing in partially-shaded spots. The large, umbrella-like leaves are 18 inches across and 2 feet high. The heads of rosy-pink flowers appear in spring, before the foliage, giving a quaint appearance.

SPIRÆAS.—The noble Goat's-Beard, *Spiræa Aruncus*, is another fine flowering plant worthy of extended cultivation. It is a gross feeder, and requires a similar treatment to the *Gunnera*. *S. gigantea* and *S. palmata* are other good garden species. The newer *Stenanthium robustum* is very ornamental, and should find a place in the pleasure grounds.

THE FORMAL GARDEN.—The spikes of Hyacinths, Daffodils, Jonquils and early Tulips should be secured to stakes or other supports. Keep the surface of the beds lightly hoed after a little fertiliser, such as Clay's or With's, has been spread on the surface. Common soot may also be employed as a dressing.

BEDDING PLANTS.—As soon as the cuttings of plants for the summer flower beds are well rooted, whether struck in the autumn or early spring, remove them from the glasshouses into cold frames, and harden them gradually. In fine weather they may be fully exposed during the daytime, and a little ventilation afforded at night, but not when strong winds are blowing or the weather frosty. If properly attended to they will make sturdy, floriferous plants before the time for planting-out arrives, and will grow in the beds straight away, producing a good effect almost immediately. Their removal from the houses will permit of the propagation of such tender plants as *Coleus*, *Irisene*, and *Alternanthera*. Like many other gardeners, I have discontinued cultivating *Alternanthera* and plants of that type, for I doubt the wisdom of growing under glass for some nine months of the year subjects that are of value in the flower garden for only a short period. There are other plants of a hardier nature that will flower earlier and remain in bloom for a much longer period, of which *Antirrhinums*, *Verbenas* and *Salvias* are examples.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOTE,
Eastwell Park, Kent.

PERPETUAL-FRUITING STRAWBERRIES.—The chief value of these Strawberries in the average garden is to supply berries in the autumn. To ensure late fruiting remove all the flower-spikes as soon as they appear in the usual flowering season, and continue to do this until about the latter part of July. The flower-spikes thrown up after this date may be allowed to develop, and if the plants are well cultivated some good dishes of fruit will be available late in the season. In unfavourable autumns it is wise to cover the plants with glass lights in order to develop the flavour in the fruit, and it is well worth the trouble involved. The plan followed here is to plant strong, young runners in the spring in a warm, sunny border, as the greatest possible amount of sun is necessary to bring this late crop to perfection. The ground, having been prepared as recommended above, should be forked when in good order for the work, and the runners planted at once. Allow a distance of two feet between the plants, and if the weather is dry damp them

overhead occasionally until the roots are well established. Hoe the beds regularly, and when hot weather sets in mulch the roots with decayed manure; afford the plants liberal supplies of water during times of prolonged drought. Varieties recommended for autumn fruiting are *St. Antoine de Padou*, *St. Joseph*, and *Laxton's Perpetual*.

PROSPECTS OF THE FRUIT CROP.—Though the weather of the past winter was exceptionally mild, with very little frost, the fruit-trees generally in this district are considerably later than usual in coming into flower. In March more than 5 inches of rain fell on twenty days, and vegetation of all kind made slow growth in that month. But fruit trees of all kinds look very promising for bountiful crops. Apricots and Peaches on warm walls are a mass of bloom, and at the time of writing the weather is favourable for the setting of the fruits, for bright, sunny days are followed by dull nights, with an even temperature. Apples, Pears, Cherries, and Plums are, nearly without exception, laden with plump fruit-buds, and in early districts the blossoms are on the point of bursting; in fact, some have expanded their petals already. Small fruits, such as Gooseberries and Currants, are also looking well. In cold, exposed districts, or in gardens near to a large body of water, every effort should be made to protect the blooms of choice fruit trees when the temperature falls suddenly. Strawberries are starting strongly into growth; but few of these plants died during the past winter, and the crowns look plump and healthy.

BLACK CURRANTS.—The rapid spread of the mite which causes "big bud" has made the cultivation of Black Currants a matter of great hazard, for no variety is immune from attack, although such strong, vigorous sorts as *Boskoop Giant* seem able to resist the pest for a time; but, sooner or later, even these become infested. May is the best time to take measures for combating the mite, and continued vigilance must be exercised, for if left undisturbed, the pest quickly ruins whole plantations. If the bushes are old, with weak, scrubby growth, it is advisable to grub them up and burn them at once. Young bushes should be cut down to the ground level, the surface soil removed and burnt, and fresh soil substituted as a top-dressing. The plants will start strongly into growth, and it will be a simpler matter to remove any big buds that are detected on the young shoots. Hand-picking should first be carried out and the bushes afterwards sprayed with a mixture of soft soap and quassia extract, in the proportion of 2oz. of the former to 4oz. of the latter to each gallon of water. Another remedy which is strongly recommended is that to dust lime and sulphur liberally over the bushes and also on the ground underneath. The work should be done on a damp day, so that the materials will adhere to the branches. Two parts of sulphur to one part of unslaked lime should be well mixed and applied several times during the next two months.

YOUNG PLANTATIONS.—Young bushes must not be planted where old ones have been grubbed out because of infestations of the mite. They should be grown on ground far removed from the old plantation. Black Currants repay a generous treatment, and the ground for this crop should be thoroughly well cultivated. Watch carefully for the first appearance of the mite on the young bushes and adopt measures to prevent the pest from spreading directly its presence is detected.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY,
Knowsley Hall, Lancashire.

COLEUS THYRSOIDEUS.—Plants of this blue-flowered *Coleus* are getting over and should be rested in a pit having a temperature of 60° after first removing the old spikes. About the end of the present month they may be induced by frequent syringings to produce shoots for cuttings. The cuttings may be taken off when 2½ or 3 inches long and inserted in pots and pans filled with light soil. Pot the cuttings as soon as they are rooted into 60-sized pots, placing two plants in

each pot. When they have grown about 9 inches high stop the growth to cause side shoots to develop. Re-pot as required into 6-inch pots and grow the plants in a temperature of about 60° throughout the summer. Seed may be sown now and the seedlings grown as advised above.

GREENHOUSE CALCEOLARIAS.—These plants have filled their pots with roots, and the flowers are showing signs of colour. At this stage they should be grown under very cool conditions, and the roots fed twice weekly with liquid manure suitably diluted. Practise overhead sprayings on bright days, using a fine sprayer, and fumigate the house on frequent occasions to destroy aphids, which spreads rapidly and soon causes considerable damage. When the flowers have expanded shade the plants for a few hours during the brightest part of the day. Birch twigs placed neatly around the edges of the pots will support the flowering shoots, or a central stake may be used, and the growth slung to this.

CHINESE PRIMULAS.—Seeds of both the sinenses and star varieties should be sown now if plants are required for blooming in autumn. Sow in shallow seed-pans, provided with plenty of drainage and filled with a mixture of sifted loam and leaf-mould in equal parts, with plenty of sand added. Press the soil firmly in the pan and moisten it with tepid water. When the soil has drained, sow the seeds evenly on the surface and cover them with either sand or fine soil to a depth of about one-sixteenth of an inch. Lay on the pan a piece of slate or glass covered with paper, and germinate the seeds in a temperature of 60° to 70°. When the soil needs moistening hold the pan in a bucket of water nearly up to the rim until it is thoroughly wetted. Shade the seedlings during times of bright sunshine.

PROPAGATING PRIMULAS BY SIDE SHOOTS.—The present is a suitable time to propagate double varieties of Primulas from side shoots treated as layers. Remove all the flower spikes and some of the lower leaves on each growth. Fill the pots to their rims with light soil—a mixture of leaf-mould and sand in equal proportions is suitable—and peg the shoots into this. Roots will soon develop, when the layers may be severed from the parent plant and potted singly into small (60 size) pots. Shade from bright sunshine and keep the frame close until the plants are well established. *Primula obconica* may be propagated in the same manner or the plants may be turned out of their pots, the ball of soil reduced, and the roots divided into two or three portions. Pot the latter singly into receptacles just sufficiently large enough to accommodate the roots, and afford water with extra care until they become re-established.

CALADIUMS.—These ornamental-leaved plants are growing freely and require repotting. Use compost of an open texture—a mixture of equal parts fibrous loam, lumpy peat, and well-broken manure with sufficient charcoal and sharp sand added to lighten the materials will be suitable. In order to avoid a check to growth, let the compost be warmed and, if practicable, it may be brought into the house where the plants are growing, and the repotting done there. If the plants are brought out of the house into a potting shed, see that no cold draughts reach them, as the leaves are delicate and soon injured. After one copious watering, afford moisture with extreme care until the roots are well established, but syringe the bare spaces frequently to promote plenty of moisture in the atmosphere, as humidity is beneficial to these plants. Grow them in a temperature of 70°.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHES BILD), Buckinghamshire.

PINES.—The proper airing of Pine plants is an important detail in their cultivation, for without careful attention to this matter it is impossible to secure that sturdy habit of growth which is indispensable to the production of fine fruits. At this season ventilation requires to be done with extra care, especially when the plants are grown in close pits, the winter growth being

specially liable to injury from sunshine. The temperature of the fruiting-pit may be 70° at night, with 75° by fire heat on sunless days, and 85° to 90° with sunshine. Admit a little air early in the mornings, and when the temperature rises to 80° admit air by the front ventilators also, but draughts of cold air must not be permitted. Raise the temperature in houses where successional plants are grown to 65° or 70° at night, and to 75° by fire heat on dull days; in sunny weather it may range from 80° to 90°. As soon as the plants of each batch of suckers are rooted proceed with the potting of them. The night temperature may be increased to 68° or 70°, allowing a rise of 10° or 15° by day.

FIGS.—Reduce the amount of root-waterings gradually in the case of pot-trees with fruits showing signs of ripening, but give sufficient moisture to keep the foliage in a healthy condition. The amount of atmospheric moisture should also be less, and rather warmer and drier conditions maintained whilst the fruit is ripening. Trees planted out with the fruit swelling require liberal supplies of water or liquid manure. A light mulching of half-decayed manure will help to maintain a uniform condition of moisture in the soil as well as afford nourishment to the roots of the trees. Judicious top-dressings of this kind aid considerably in perfecting the current crop of fruit, besides stimulating the tree for the second or following crops. Continue to pinch and thin out growths where the trees are inclined to become overcrowded, as both wood and foliage require full exposure to sunlight throughout the growing season in order to secure a good crop the following season.

MELONS.—Plants with fruit swelling require much heat and moisture. Indeed, at this stage the atmosphere should be fully saturated now that the sun's heat is increasing. Admit air freely during the early part of the day, but close the house early in the afternoon to husband all the sun heat possible in preference to hard firing. Maintain the bottom heat at about 75°. Plants that are showing fruit should have an abundance of air in favourable weather, and the atmosphere should be somewhat drier than hitherto. Pollinate only the strongest flowers; drought at the roots is often the cause of the fruits failing to set, but the trouble may also result from an excess of moisture. Therefore, exercise great care in watering, and restrict the rooting space as advised on p. 167. The pinching and training of the shoots should be done regularly, so that growth may not be overcrowded at any time. In doing this work take care not to injure the mature foliage. Canker and gumming frequently follow bruises on the stems caused by careless handling of the water-pot, or by tying the stems and branches too tightly. Make another sowing to raise plants for successional fruiting. Those who grow Melons on hotbeds or in pits should set the plants in position as soon as the beds are in a proper condition. Some growers place single plants in inverted seakale pots, or receptacles of a similar size, afterwards plunging these in the hotbed, and it is claimed that better results follow this method than when the orthodox plan of planting on ridges or mounds is practised. Pinch the shoot at the fifth or sixth joint to cause the plants to develop laterals as quickly as possible.

CUCUMBERS.—The best system to adopt in training Cucumbers depends to some extent upon circumstances. If space is limited, the plants may be stopped when about 6 or 7 inches high, but where there is plenty of room they may be allowed to grow several feet before being pinched. If trained on wires the shoots should be about 12 or 15 inches from the roof-glass, and the leaders stopped when they have grown to the desired length. The side growths will produce fruit, and each shoot should be tied securely at the joint where the fruit is produced. Stop each growth at the joint beyond the fruit, unless more space is required to be furnished. Syringe twice daily in fine weather, and close the house early in the afternoon, as soon as the syringing has been done. If the

plants are growing in frames, damp the surface of the beds daily, and afford water liberally when the plants require moisture, feeding with liquid manure at least once a week.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

FRENCH BEANS.—Where there is space under glass to plant a lesser or greater number of an early variety with sufficient heat to keep the plants moving, a very desirable addition to the early summer vegetables will be provided. Dwarfs crop much sooner than climbing varieties, though the pickings from the latter are considerably longer. Osborn's Forcing is still a valuable variety for growing indoors.

RADISHES.—Where there is a constant demand for Radishes sowings of French Breakfast variety should be made at intervals of a week to ten days; to save thinning the crop, place seed singly in shallow holes made at 2 to 3 inches apart. An old, worn wooden rake is admirable for making the rows, as the teeth are at the right distance apart.

BEET.—A small sowing of Beet may be made in gardens in favoured localities, though it is too soon for late districts. Beet succeeds best in very fine soil, and before sowing see that the ground is pulverised to a depth of several inches. A few seeds should be dropped at every 6 inches in rows 15 to 18 inches apart. The seeds should not be deeply covered, and made only slightly firm in the ground, if at all. Dell's Crimson, White's Black and Covent Garden are three good varieties.

ONIONS.—Plants in boxes intended for planting shortly should be exposed to all weathers except frosts, and not over-watered. When prepared by a short course of semi-dryness at the roots they bear all the more kindly the slight disturbances due to transplantation. If time permits, the ground set apart for the crop should be dug deeply and all clods that have resisted weather influences broken down. A slight dressing of well-decayed manure worked in when digging will help the young plants to make a good start.

ASPARAGUS.—The present is a suitable time to sow seeds of this vegetable, and if it is not intended to transplant the seedlings the rows should be 18 inches apart with 4-foot spaces after every third line. The beginning of growth of 2 to 3 year-old plants indicates the proper time to lift these to make new plantations. Plant slightly deeper than the plants were previously. If the garden is exposed to high winds it is almost essential to provide supports to the plants which otherwise would be twisted and thus damaged.

CUCUMBERS.—With increased light and sun heat the plants will grow at a greatly accelerated rate, and should be helped with surface dressings composed of equal parts rough turf and rotted manure. Soot-water and diluted manure-water are also valuable fertilisers. The growths should on no account be allowed to extend unless to take the place of worn-out shoots. When the growths are regularly stopped beyond each fruit and only a limited number of fruits permitted to swell at the same time, the plants continue in the best possible condition for a long time. Occasional vaporisings with nicotine preparations is a sure preventive of insect pests. Plants should be prepared for summer cropping in manure-heated frames or pits. In the meantime the plants should be grown in a heated pit.

CAULIFLOWERS.—Plants in pots from the January sowing may be exposed to the weather, but in a sheltered position and provided with means of protection on frosty nights or mornings. When watering let the liquid be strengthened with manure, but not over much. It will have the effect not only of preserving the plants in vigour, but also of aiding in the production of young roots. The ground should be prepared in advance, and receive a thick dressing of rotted manure, which should not be dug too deeply in the soil.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, April 13—

Bank Holiday.

TUESDAY, APRIL 14—

Kingsbridge Daffodil Spring Fl. Sh.

WEDNESDAY, APRIL 15—

Roy. Hort. Soc. Coms. meet (Special Daffodil Show, 2 days.)

THURSDAY, APRIL 16—

Manchester and N. of Eng. Orchid Soc. meet. B.G.A. (Watford branch) meet.

FRIDAY, APRIL 17—

Huntingdon Daffodil and Spring Fl. Sh.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 46.5°.

ACTUAL TEMPERATURES:—

LONDON, Tuesday, April 7 (6 p.m.); Max. 52°; Min. 41°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Wednesday, April 8 (10 a.m.); Bar. 29.3°. Temp. 51°. Weather—Fine.

PROVINCES, Tuesday, April 7. Max. 48°, Aberdeen; Min. 45°, Lancaster.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Hardy Bulbs and Herbaceous Plants at 12; Roses at 1.30; Palms and Plants at 5. Trade sale of miscellaneous Bulbs at 12; Japanese Liliums at 2.45. By Protheroe and Morris, Rose Trees, Liliums, Perennials, etc. At Stevens's Rooms, 38, King Street, Covent Garden.

FRIDAY—

Imported and Established Orchids, at 67 and 68, Cheapside, E.C. By Protheroe and Morris, at 12.45.

Maize.*

It is symptomatic of the change in appreciation of relative values that the Right Hon. Louis Botha, to whom Mr. Burt-Davy's book is dedicated, holds the dual post of Prime Minister and Minister for Agriculture of the Union of South Africa. The fact is significant not only because of General Botha's keen interest in agriculture, but also because it shows that South Africa is alive to the great problem which lies before it—that of establishing agriculture before the other great South African industry passes into an inevitable, albeit as we hope far-distant, decline.

Mr. Burt-Davy, in his capacity of Government Agrostologist and Botanist in

the Department of Agriculture of the Union of South Africa, has had great opportunities for gaining knowledge of the plant about which he writes, and he has used those opportunities well.

That the Maize plant is worthy of the extended treatment meted out to it in this work will be evident when it is realised that Maize stands first in productiveness of all crops whatsoever. The total world's crop is no less than 3,875 million bushels, with Oats a far outpaced second (3,532 million bushels), and Wheat a close third with 3,428 millions, and Rice 3,203 millions, winning easily from Rye and Barley, the annual yields of which are considerably less than half that of Maize. In spite of the enormous production of Maize the world absorbs it readily, and although the United States raises 2,927 million bushels per annum, it consumes almost the whole of that vast amount, and exports only 1½ per cent. This means, of course, that the consumption of Maize by the people of the United States is enormous; as indeed is the case, for no less than 25½ bushels of Maize are consumed on the average by an individual American. Indeed, as the Professor of Economics of Harvard has said, Maize is the leading product of America.

The yield from the Maize industry is estimated as greater by five million pounds sterling than the yield from the manufacture of iron and steel. Mr. Burt-Davy, with his eye on these facts, aspires to make of South Africa a great Maize producing and exporting country—in fact, the Maize granary of Europe. So far as climate goes South Africa enjoys an advantage over the States; for the percentage of moisture in the grain exported is 5 per cent. less than that in American-grown Maize.

Needless to say our knowledge of the origin of this plant is meagre in the extreme. That it originated in America appears to be certain; but from what wildling the Maize has sprung is unknown. Some hold that it is descended from the Teosinte plant (*Euchlaena mexicana*), and affording some measure of plausibility for this origin is the fact that Teosinte is the only known plant which hybridises with the Maize. Support of an indirect nature is also supplied by the results in later generations of crossing these two plants. As Mr. Burt-Davy points out, the first and second generations of the cross consist of plants which for the most part resemble Teosinte. This, we think, was to be expected if the Maize has developed by the loss of a considerable number of factors, and if, therefore, the several characters of Maize are due to the absence of a number of factors.

From the practical point of view these cross-breeding experiments have proved useless for the immediate purpose for which they were instituted, that of conferring on Maize the greater resistance to chlorosis possessed by Teosinte.

Mr. Burt-Davy recognises clearly that if South Africa is indeed to become the Maize granary of Europe it must improve its methods of cultivation. He

shows us on the one hand that heavy crops may be and are produced in suitable parts of the Union—for example, yields of 35½ to 42½ bushels have been obtained on the Government Experiment Farms—and on the other hand that the average yield in the Union is so low as 14-18 bushels. In contrast with this poor result Mr. Burt-Davy puts the yields obtained in America—where good farmers grow 75-100 bushels of Maize per acre, and where without manure the average yield is half as much again as the average in South Africa. Nothing is more impressive in Mr. Burt-Davy's comprehensive account of the Maize than the description of the amount of systematic labour which has been and is being devoted in the United States to the further improvement and increase of the crop. It is in applying such labour and system that the author hopes to do for South Africa what the many workers and investigators have done for America.

That this is in course of achievement is shown by the excellence of the chapters on the "Improvement of Maize by Breeding."

To review the many aspects of the Maize problem treated of in this volume is beyond the space at our disposal, and we must conclude by congratulating both Mr. Burt-Davy on the success of his great undertaking and the South African Government on having the services of such a hard working and able agricultural officer as the author of this work.

Coloured Supplement.—Our Supplementary Illustration is reproduced from Mr. CORY's souvenir volume of the Royal International Exhibition, and represents the pretty hybrid *Cypripedium Maudiae*. It is from a cross between *C. callosum* Sanderae and *C. Lawrenceanum* Hycanum ♀, and was first exhibited by Messrs. CHARLES WORTH AND Co. in 1900.

SALE OF THE WESTFIELD ORCHIDS.—The sale of Mr. FRANCIS WELLESLEY's small but choice collection of Orchids was conducted by Messrs. PROTHEROE AND MORRIS, at their rooms, on the 2nd and 3rd inst., and the event resulted in a notable gathering of orchidists. The 500 lots were offered without any reserve and realised £1,244. Fine varieties of *Cattleya Mendelii*, *C. Mossiae* and other species, and albinos, realised fair prices. The seedlings, both in store pots and small single plants, sold well; so also did showy *Iaelio-Cattleyas*. *Cypripediums* generally were cheap, although a few of the best and rarest realised high prices.

SURVEYORS' INSTITUTION.—The next ordinary general meeting of the Surveyors' Institution will be held in the lecture hall of the Institution on the 20th inst., when a paper will be read by Mr. DAWBARN YOUNG, entitled "Comments on the Land Enquiry Committee's (Urban) Conclusions." The chair will be taken at 8 o'clock.

FINCHLEY CHRYSANTHEMUM SOCIETY.—At a recent meeting of this Society held at the residence of the President (J. J. WARD, Esq.), Mr. E. J. FROOME was appointed secretary, to succeed Mr. W. J. DRUETT.

NATURE RESERVES IN CUMBERLAND.—With the object of protecting the local fauna in Cumberland a committee has been formed, with the Speaker as president, to set apart tracts of

* *Maize: Its History, Cultivation, Handling, and Uses with Special Reference to S. Africa.* By Joseph Burt-Davy. Pp. 831, illustrations 245. (Longmans, Green and Co.) 25s. net.

natural ground as reserves, one such tract, Kingmoor, near Carlisle, having been already secured. A "watchers' fund" to provide keepers for such reserves is being formed, and a close watch is to be kept on nesting ravens, peregrines, and buzzards throughout the country.

APPOINTMENT TO THE ROYAL BOTANIC SOCIETY.—MR. GEORGE KELE, gardener to A. W. MERRY, Esq., Danesbury, Hertfordshire, for the past six years, has been appointed head gardener to the Royal Botanic Society, Regent's Park. Before going to Danesbury, Mr. KELE was gardener for a number of years to Miss ADAMSON, South Villa, Regent's Park.

PRESENTATION TO MR. MATTHEW TODD.—On the occasion of the attainment of his diamond jubilee in the seed and florist trades, and to celebrate his appointment as a Justice of the Peace for the county of Midlothian, Mr. MATTHEW TODD, head of the Edinburgh firm of TODD AND Co., was made the recipient of a testimonial subscribed to by a large number of his friends to mark their appreciation of his services to horticulture, and of the honour conferred upon him. The presentation, which took the form of a handsome barograph and a purse of sovereigns, took place in the presence of a large gathering in the Royal British Hotel, Edinburgh, on the 3rd inst. Mr. DAVID KING, Murrayfield, president of the Scottish Horticultural Association, and one of Mr. TODD's oldest friends in the trade, made the presentation. In thanking the subscribers Mr. TODD drew many interesting comparisons between the conditions obtaining in the seed and florist trades now and sixty years ago, and gave an interesting résumé of the progress which both businesses had made in that time. A number of ladies and gentlemen contributed songs and recitations in the course of the evening.

HYACINTH SMUT.—Miss IVY MASSEE contributes to the *Journal of Economic Biology* an interesting account of her researches on the smut fungus, *Ustilago Vaillantii*, Tul., which is a parasite of various Liliaceous plants—*Scilla bifolia*, *Muscari comosum*, *Hyacinthus romanus*, and others. Miss MASSEE has proved by infection experiments the correctness of the view put forward originally by Mr. GEORGE MASSEE, that infection only occurs in the seedling stage. The spores in contact with seedlings germinate, gain entrance to the plant, and the mycelium takes up its position in the cushion or rudimentary stem of the young plant. There it remains and perennates. The mycelium enters the flower-stalk at an early stage, grows as it grows, and finds its way into the anthers of the flower. There it develops rapidly, and as a result the anthers contain smut spores instead of pollen. In rare cases spores are formed also in the ovules. Attempts to infect healthy anthers having failed, Miss MASSEE concludes that, as is the case with certain smuts of cereals, the plant is attacked only in the seedling stage.

SELF-STERILITY OF CHERRIES.—Investigations carried out at the Oregon Agricultural College show that the following varieties of Cherry are self-sterile:—Bing, Black Republican, Black Tartarian, Coe, Early Purple, Elton, Knight Lambert, Major Francis, May Duke, Napoleon, Rockpost, Waterhouse, Williamette, Windsor and Wood. Of these some—for example, Bing, Lambert and Napoleon, the three chief varieties cultivated in Oregon—are inter-sterile, that is, they do not set fruit when pollinated either with their own pollen or with that of the other varieties. The best pollenisers are Black Republican, Black Tartarian and Waterhouse; but Coe, Early Purple, Elton, Major Francis and Wood are also good. It is noteworthy that according to these observations some of the Duke class of Cherry are capable of

pollinating certain of the Bigarreau class, and that some Bigarreaus set fruit when pollinated with the pollen of varieties of *Prunus Cerasus* (the sour Cherry). Hence it would appear that inter-sterility does not depend on degree of relationship.

MAIZE IN ARGENTINA.—The Board of Agriculture and Fisheries has received the following telegram from the International Agricultural Institute: "The estimated production of Maize in Argentina is 177,158,000 cwts., or 80.2 per cent. above last year's production."

THE "THOMSON" CHALLENGE TROPHY.—The Silver Cup illustrated in fig. 111 has been presented to the Royal Caledonian Horticultural Society by Messrs. WILLIAM THOMSON AND SONS, LTD., Clovenfords, and will be offered at the autumn exhibition for the best exhibit of six bunches of Grapes. The trophy, which must be won three times by a competitor before becoming

FIG. 111.—THE "THOMSON" CHALLENGE TROPHY FOR GRAPES.

ing his property, is to take the place of the Silver Cup offered by Mr. W. H. MASSIE, of Edinburgh, and won outright last year.

EELWORM IN NARCISSUS BULBS.—Experiments carried out by Mr. T. R. HEWITT and published in the official *Journal* of the Department of Agriculture, Ireland (January, 1914) claim to show that eelworm in Narcissus bulbs may be destroyed by soaking the bulbs in 5 per cent. copper sulphate. It is stated that the solution penetrates readily and kills the eelworm. The statement is very remarkable and requires substantiation. If it proves true it will constitute not only an observation of considerable service in practice, but also a discovery of very great scientific interest, for, as is well known, copper sulphate is exceedingly poisonous. Yet it is claimed that this poison penetrates the tissues of the Narcissus and destroys the eelworm without damaging the plant. We should advise extreme discretion in the use of this method, in spite of the good results which are claimed for it; for, although open to conviction, we are at present entirely sceptical as to this beneficent discrimination in destruction on the part of 5 per cent. copper sulphate.

RUST-PROOF ASPARAGUS.—An interesting account is given by Mr. J. B. NORTON, of the U.S. Department of Agriculture, in *The American Florist*, of the attempts which are being made to breed rust-resistant varieties

of Asparagus. The cultivation of Asparagus in America received a severe check in 1895 when the Asparagus rust (*Puccinia asparagi*) made its appearance. Introduced from Europe into New York State, it spread rapidly and reached the Pacific coast in five or six years. The only varieties which proved relatively immune were Palmetto and Argentine. In recent years attempts have been made to produce from the more resistant strains a race of Asparagus which shall prove completely immune to rust. Preliminary tests of varieties in cultivation showed that the most resistant male plant is New American, and the most resistant female Reading Giant. Crosses between these forms appear to show that the power of resistance to rust is inherited. By subsequent selection strains with a high degree of immunity have been obtained. Of species allied to Asparagus officinalis, the Chinese *A. devaricus* is nearly immune, and has given fertile hybrids when crossed with a rust-resisting male of the common species.

ORANGE FLOWER CULTIVATION IN FRANCE: DISCUSSION IN THE CHAMBRE.—Speaking

in the Chamber of Deputies on the 25th ult. in favour of an increased Customs tariff on certain essential oils, M. GILLETTE-ARIMONDY gave some interesting details on the culture of the Bigaradier, or Bitter Orange tree, the species cultivated for the production of "neroli" and "petit grain" perfumes. He produced specimens of the flowers and leaves of this tree, remarking that oil of neroli was distilled from the former and petit grain from the latter. This tree is only grown in France in the Alpes Maritimes district (the Riviera), and flourishes at an altitude of not more than 100 to 200 yards above sea level, in well-sheltered and sunny spots. It is necessary to dig the soil thoroughly, 8 inches deep at least, manure liberally and water twice or oftener during the dog days. The manure should be of nitrogenous nature. No other crop can be raised between the trees. The malady known as "fumagine" (due to a small insect like the cochineal) must be fought against by anti-cryptogamic treatment, and the *Crisomphalies mundi*, the worst foe of the Orange tree, destroyed by cyanhydric washings. Chilly spring mornings are to be feared; a cold April night may injure or even ruin a crop. Briefly, the culture is full of risk. Picking begins in April, and is at its height in May. Double ladders are set up around the trees. Men mount the highest rungs; the women work below, the children nearest the ground. Expert pickers use both hands; others have to use one hand to steady themselves on the ladder. All wear an apron, tied up in front to form a pocket or pouch, into which the flowers are thrown. An expert male picker, if the trees are well flowered, may gather 30 lb. or more a day; women seldom exceed 20 lb., children 8 to 12 lb. Piecework has always been the rule. A penny a kilogramme (about 2 lb.) was the rule a hundred years ago; it has been increased to 1½d. and to 2d., and last year a few growers paid their pickers 2½d. per kilo. The trees are planted in regular rows, each about 7 feet from the others. This gives 400 trees per hectare, and as the average yield per hectare is four tons, the production per tree may be taken as about 20 lb. Ten years of preliminary work is necessary to form an Orange grove, and the trees only bear their maximum of flowers when 25 years of age. The total French crop of Bitter Orange flowers is between two and three thousand tons, so that the amount of home-produced neroli oil is from two to three tons. Much is imported from Paraguay and used in French perfumery; the exact amount is not separately stated in the French Custom statistics. M. GILLETTE-ARIMONDY stated that the actual yearly cost of cultivating a hectare of Bigaradiers and gathering the flowers, distilling and selling, was 1,800 fr. (£72), and that

at recent prevailing prices the peasant only obtained 1,400 fr. (£56) for the produce. This was because the price of neroli oil was kept low by the imported article. Petit grain oil is produced from the leaves and twigs annually lopped from the Bigarediers, about 130 lb. of these being required to produce a pound of oil. France annually produces between 10 to 12 tons of this product, while from 30 to 40 tons are imported, mostly from Paraguay. A by-product of the Bigaredier is Orange-flower water. A ton of flowers, the speaker stated, would produce £6 to £8 worth of water, in addition to the 2 lb. of neroli oil already mentioned. Pure neroli oil is worth (cost price) £14 (350 fr.) per kilo. Some of M. GILLETTE'S figures were disputed by his critics, but as an increase in the Customs duties on the oils was voted by the Chamber of Deputies his asseverations were evidently accepted by the majority of his colleagues.

FORESTRY: A PLEA FOR WORKING PLANS.—

A correspondent writes us as follows:—"If one were to believe the statistics issued annually by the Board of Agriculture and Fisheries, the area of land growing trees is increasing. This may be all very well on paper, but it does not convince the practical man who is engaged in forest valuations all over the country. Full well does he know that the growing stock of timber is largely overdrawn, and year by year this over-draft is increasing until the vanishing-point is almost in view on most of the largest estates in the country. It is questionable, indeed, if there are half-a-dozen estates in Great Britain where the annual yield of timber per acre is known even approximately. There are no form factors recognised in this country, yet it would not be a difficult matter to ascertain how much timber is annually produced upon any estate. In an estate embracing 1,000 acres of woodlands, where the annual increment worked out at 40 cubic feet per acre, the owner would know that he could dispose of 40,000 cubic feet of timber every year without making any drain upon the growing stock of timber. We have no rule at present for the disposal of growing timber, hence the great necessity that exists for making a forest working plan upon every woodland property. This would serve a double purpose, for the owner would be aware of the quantity of timber he could sell, and the timber merchants in the vicinity would also know how much timber would be disposed of from every property in the neighbourhood, and could prepare their plans accordingly. As matters are at present this is impossible owing to the haphazard fashion in which home-grown timber is placed upon the market—a famine and a glut alternating at irregular intervals. Another point to which attention may be directed is the well-known fact that whenever a change of management takes place upon an estate the new management endeavours to go one better on the record of his predecessor, and in all probability both dispose of more timber than the woods under their charge are growing. To overcome the uncertain and most unsatisfactory system now prevailing on woodland estates, nothing could be more beneficial than for proprietors to adopt forest working plans. By doing so they would find that it would not only be for their own benefit, but also for the benefit of the wood merchants as the latter could afford, and would give, better prices than they now do for the trees they buy."

PLUM CULTIVATION IN CANADA.—Mr. W. T. MACOUN, Dominion Horticulturist, Central Experimental Farm, Ottawa, has published in Bulletin No. 43 a revised edition of his useful account of the cultivation of the Plum in Canada. He points out that the parentage of Canadian Plums is very mixed, the Plums of the present day being derived from (1) the European Plums, which have or may have sprung from *Prunus domestica*, *P. insititia* and *P. cerasifera*;

(2) the Japanese (*P. triflora*); (3) the American (*P. americana*, *P. nigra* and *P. hortulana*); (4) the Chinese *P. Simonii*; and (5) the North American Western Sand Cherry (*P. pumila* Besseyi). The European Plums succeed best in the more genial parts of Canada—for example, in S.W. Ontario—and the Niagara peninsula, and also in Quebec, along the south shore of the St. Lawrence, on Prince Edward Island, and in the warmer parts of Nova Scotia and New Brunswick. They do extremely well in Vancouver and the lower mainland of British Columbia. In the prairie provinces, however, the European Plums are found to lack hardiness and are winter-killed. The failure appears to be due—at Ottawa, at all events—to low winter temperature than to the destruction of flower-buds by dry, cold winter weather and spring frosts. Japanese Plums introduced in 1870 have been widely planted, but though prolific and of good keeping quality and appearance, they are generally only of medium quality; nor are the Japanese Plums, as a rule, so hardy as the European. The Simon or Apricot Plum, *Prunus Simonii*, probably of Chinese origin, was introduced into America from France about twenty years ago. Though of service, perhaps, for cross-breeding, it is not recommended for planting. The best varieties of American Plums derive from *Prunus americana* and possess the advantage of blooming later than those from the Canadian Plum (*C. nigra* Ait.). Having regard to the fact that the American Plum has been cultivated only for sixty years the improvements which it has undergone are remarkable. Nevertheless, there is yet room for further improvement in the skin, which is apt to be tough and thick, and in the flavour, which, however, is fairly good. Mr. MACOUN predicts that from among cultivated varieties of *P. nigra* will be found the Plums for the colder parts of Ontario and Quebec. The progeny of this species (or geographical form of *P. americana*) flower early and ripen quickly. Of hybrid Plums, Mr. MACOUN mentions that few of Burbank's raising have proved valuable in the severe climate of Canada. Omaha, a hybrid between Japanese and americana, is an early Plum which is proving useful at Ottawa, and it is suggested that further breeding between the cultivated varieties of the several species may result in forms which will grow in yet more northerly districts of the Dominion.

POISONING BY RHODODENDRONS.—A recent case of poisoning of cows by Rhododendrons is reported in the *Journal* of the Board of Agriculture. The article cites previous cases of poisoning of sheep, calves, and goats as a result of eating the leaves of *R. ponticum*, but, unlike the present case, the results were not mortal. Many species of Rhododendron are known or reputed to be poisonous. Thus *R. ferrugineum* causes frequent loss among grazing animals; *R. californicum* is said to be poisonous to sheep in Oregon; *R. chrysanthum* is known to be poisonous, as also is *R. cinnabarinum*, as reported in HOOKER'S *Himalayan Journals*. Of the properties of Rhododendron arboreum, HOOKER wrote (op. cit.) that in East Nepal "Rhododendron arboreum becomes plentiful at 5,000 to 6,000 feet (East Nepal), forming a large tree on dry, clayey slopes. . . . In the contracted parts of the valley the mountains often dip to the river-bed in precipices of gneiss, under the ledges of which wild bees build pendulous nests looking like huge bats suspended by their wings; they are 2 or 3 feet long and as broad at the top, whence they taper downwards; the honey is much sought for except in spring, when it is said to be poisoned by Rhododendron flowers, just as that eaten by the soldiers in the retreat of the Ten Thousand was by the flowers of *R. ponticum*."

PUBLICATIONS RECEIVED.—*British Flowering Plants*. By Mrs. Henry Ferrin and Prof. G. S. Boulger. Vol. 1. Complete in four volumes. (London: Bernard Quaritch. Price twelve

guineas.—*Transactions and Proceedings of the California Association of Nurserymen*. Secretary, Mr. Henry W. Kruckeberg, Los Angeles. Price 50 cents.—*Les Amis de Roses*. (Colombo: Department of Agriculture, Ceylon.)—*Wissenschaftliche Ergebnisse der Deutschen Zentral-Afrika-Expedition, 1907-1908*, unter Führung Adolf Friedrichs. Band II. (Leipzig: Klinkhardt and Biermann.) Price M. 4.20.

VEGETABLES.

RAISING SEEDLINGS.

Owing to wet weather in March the work in the kitchen garden is greatly in arrears, especially in such gardens as ours, where the soil is heavy and retentive. Seed sowing has been out of the question. The advantages of raising the seedlings under glass and planting out immediately favourable weather comes will prove a great gain this year to all who have practised it. The majority of vegetables answer well to such treatment, and better results always follow this method on cold stiff ground, let the character of the season be what it may.

Assuming that the ground has been properly prepared by manuring, trenching, or digging, take the first opportunity to rake the surface level for receiving the young plants, and all hands that can be spared should be employed to set the crops into their permanent quarters. Boards should be employed to save treading the ground. Peas and Broad Beans give far better returns when treated in this manner. Raise them in a cool place, never allow them to become drawn, and thoroughly harden them before planting. Slugs are likely to prove troublesome this spring, and the best preventive is a good coating of finely-sifted cinder ashes placed around the crops. Peas should be staked and protected from birds at the same time.

Cauliflowers, Brussels Sprouts and Cabbages should be pricked out into shelters just before the first rough leaves develop. The best method of ensuring a good crop of Onions is to sow in boxes and plant the seedlings out during April, as the plants will then be safe against attacks of the Onion fly, and the crop can be harvested much earlier than if sown in the open. Both Runner and Dwarf Beans for early crops are much better raised in cold frames, pots, or boxes, and planted out as soon as danger from frost is past. These crops will be found to make much better headway than if sown in the open garden.

AUBERGINE (EGG PLANT).

THE large, purple variety of Aubergine is much the best. The plants should be grown in a hot, moist house, and saved from check at any stage. Three transplantings are necessary—first, from the seed-pans to small 60-sized pots; later, when plenty of roots are made, into 6-inch pots; and, finally, into 8-inch pots, in which they will fruit. Let the pots be well drained, and for compost use a mixture consisting of three parts loam and one part finely-sifted, well-decayed cow manure. Make the soil moderately firm, and after a good set of fruit is assured afford the roots a liberal supply of manure-water. The foliage should be well drenched with tepid water morning and afternoon to keep down attacks of red spider. For fruiting late in the summer the plants may be grown in cold frames or pits, and good results are often obtained from plants grown in the open if strong specimens are put out on a border facing south and well protected from winds. *E. Beckett.*

TREES AND SHRUBS.

A STATELY TULIP TREE.

In the *History of Horsham and Antiquities* (second edition, 1839), the gifted authoress, the late Miss Dorothea Hurst, refers to the existence of a Tulip tree (*Liriodendron tulipifera*), said to be one of the finest in England, growing in the grounds of Horsham Park, the ancient seat of the Hurst family. Horsham Park is situated between the northern confines of the town and the railway station; it is interesting to the gardener because it contains a rich collection of trees and tall evergreen shrubs which border the eastern boundary of the park, separating it from the highway leading into the town. The four boundaries of this fine, rectangular park form a plateau of rich grazing verdure, encompassed by a continuous bordering of tall, old forest trees, chiefly consisting of Oaks, Elms, Beeches and Scotch Pines, on its three sides, whilst the pleasure grounds already indicated surround the substantial mansion, situated in close contiguity to the highway. The house is a good specimen of the solid brickwork with stone facing of the latter part of the seventeenth century. It is in front of its eastern façade that the famous Tulip tree is growing, and only separated by the broad carriage drive running parallel with the substantial stone-built boundary wall. There appears to be no record of the planting of the specimen in question, but it is regarded as one of the first consignments of the plants introduced from Canada about 250 years since. As seen from the highway (North Street) the tree, standing out in bold relief, cannot well fail to attract the eye of the least observant, especially when it is in flower, some of the blooms being carried over 100 feet high. The circumference of the bole at 4 feet from the ground is 16 feet, and at the base the assemblage of surface roots, radiating around and forming an admirable pedestal-like support to the symmetrical bole, with its gigantic branches, having a spread of about 300 feet in circumference, present an effect of no ordinary character. A somewhat peculiar characteristic connected with the fruition of the Tulip tree is that it retains during the winter its crop of seed vessels, and the dark-brown colour of their involucre presents a somewhat sombre and not over-ornamental or picturesque feature. In addition to the Horsham Park specimen there are two or three others within the precincts of the town of considerable age and size, but not nearly approaching the one in question, while at Leonardslee, so famous for its Alpine and wild gardens, situated about five miles distant, there is a specimen rivalling that at Horsham Park, both in height and other proportions. *William Gardner, Horsham.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE PATENTS AND DESIGNS ACT.—As your readers are aware, the amendment of the Patents and Designs Act is now under the consideration of Parliament. We have already received a number of valuable suggestions from our Fellows on the subject, but as the Institute represents inventors generally, we shall be obliged

the exhibits are the outcome of selective triumphs contributed from many sources, foreign as well as home. We cannot fail to note that the plants themselves include far more exotics than native ones, and that in no case can any grower claim that he is only indebted to the British Isles and British growers for his acquisitions. On further examination we shall find, too, that most of the magnificent results are due to crossings between different species or genera, so that to a very large extent an element of artificiality is introduced so far as Nature pure

FIG. 112.—TULIP TREE (*LIRIODENDRON TULIPIFERA*) AT HORSHAM PARK.

if you will afford us the opportunity of appealing to all those who have not yet communicated their views to us. *Walter F. Reid, Chairman, Institute of Inventors, 20, High Holborn, London.*

THE BRITISH FERN CULT. It is a great pity that plant lovers in general fail to profit by the fact that in some peculiar way Nature has endowed Great Britain with an altogether unique branch of horticulture. If we examine into the history of all the innumerable branches of plant culture to which we owe the wonderful wealth of flowering and foliage plants exhibited at our great shows, we find in every case that

and simple is concerned. The British Fern lover, on the other hand, who has fairly mastered the capacity of variation in the few native species indigenous to Great Britain, Ireland, and the Channel Islands, can only feel regret that, despite a sort of general recognition shown in the fact that few gardens are without some specimens of the common native Ferns, a proper recognition of their wonderful variation into more beautiful types is very rare indeed. At the Great International Show of 1912, so many splendid forms were shown both by the amateur and the trade, and these were so greatly admired, that one would have expected wider recognition of these

purely native and perfectly hardy plants. Those wonderful exotics, *Nephrolepis exaltata*, and allied species, in their recent developments, are sold by the myriad, although they are tender and require warmth, while the equally beautiful, and often far more diverse forms of our Shield Ferns, Lady Ferns, Lastreas, Hartstongues, and other hardy variations are rarely seen in the places they are fitted for, such as cold conservatories and shady nooks in gardens. The connoisseur, indeed, finds it extremely difficult to understand why multitudes of people, when visiting the ferny districts of Great Britain, do their best to denude them by digging up the Ferns or pulling them out of the old walls and rocks, when for a few pence, in many cases, they could obtain far more beautiful variations or "sports" from a nursery near home. Anyone who has seen a well-grown specimen of one of our best frilled and fringed Hartstongues, or one of our beautifully crested, feathery Lady Ferns—or, better still, a choice Soft Shield Fern of the finest type—will at once admit that our wonderment is fully justified. It is not as though the material is scanty. Out of some forty odd native species Nature alone, and unaided by man's selection, has given us hundreds of different types, feathery, tasselled, or both combined, in the most curious, beautiful, and interesting ways, these hundreds being largely made up of Hartstongues, Lady Ferns, Shield Ferns, and Lastreas, all hardy and of the easiest possible culture. All these varieties have either been found wild, or have been reared from the spores of wild plants, and by selection of better types which have appeared among their offspring. It is undoubtedly to these latter, the selective improvements, that the most beautiful of all belong; but they are mostly the immediate progeny of the wild "sports," and without any selection at all the wealth of fine wild original "sports" runs well into four figures—one and all found within the limits of Great Britain. To foster these beautiful native plants the writer in recent years has undertaken the editorship of the *British Fern Gazette*, published quarterly by the British Pteridological Society for the benefit of its members, and he would be happy on receipt of a postcard to send a copy of the *Gazette* to anyone contemplating membership. *Chas. T. Drucry, F.M.H., F.L.S., 11, Shaa Road, Acton, W.*

CYANIDING TO DESTROY MEALY BUG.—The remarks of your correspondent, Mr. Shakelton (page 223), may create a wrong impression in the minds of many of your readers as to the exact point at issue. I do not think that Mr. Shakelton has proved anything new by informing us that he has been more or less successful in killing bug with cyanide of sodium of 130 per cent. strength. As a matter of fact, it is not only probable but quite possible that the sample he used was considerably below the standard quoted by me, viz., 98 per cent. pure cyanide of potassium. It would, I think, be interesting and instructive if your correspondent would consult some qualified analytical chemist and ask him to define in plain English the meaning of the term so frequently used with samples of cyanide sodium (130 per cent.). I adhere to my original opinion, that the great majority of failures may be traced to the want of a proper standard of purity in the materials used. In support of this I will quote a case in point. A very intelligent and clever amateur in this neighbourhood commenced cyaniding many years ago with varying degrees of success, but instead of purchasing commercial sulphuric acid he used instead a preparation as supplied for electric light accumulators. Having run out of this requisite he sent to me for a supply of acid to enable him to cyanide his conservatory. I need hardly state that there has been no more cyaniding done there since. Before any success could be secured, it was necessary to increase the dose of cyanide to treble the quantity required, and when acid of the proper standard was used the gas was so strong that practically every plant in the house was ruined, and several climbers killed to the ground. Mr. Shakelton should not be over-sanguine

as to the efficacious results to be obtained from sealing over the eggs of mealy bug in the cracks and crevices of vine rods with styptic or any other adhesive material of a similar nature, or he will, I fear, like myself in previous years, suffer disappointment. So long as the vines remain dormant and the seals perfect, little or no change takes place in the eggs, but as soon as the vines begin to grow freely and the wood and bark expand sufficiently to split the seals then the eggs quickly hatch, and if some effectual means are not adopted at once to check the spread of the insects they increase very rapidly, and in a few weeks defy all attempts to exterminate them, except of course that never-failing remedy, summer cyaniding. Mr. Shakelton appears to be somewhat surprised that those of your correspondents who claim success in the use of hydrocyanic acid gas should have any mealy bug in their houses, but I fail to see why he should, as I am sure he would be the first to admit that it is next to impossible to exterminate bug in a mixed house of stove plants where it has gained a firm foothold, unless there is sufficient labour to admit of a daily inspection of every plant and climber in the house, and there are few gardeners in such a fortunate position nowadays. Besides, the stove is one of the most difficult houses to cyanide successfully, owing to the nature of many of the plants and the adverse climatic conditions of the house, and as this operation of extermination should be carried out in the growing (and breeding) season, one readily understands what a difficult matter this is to accomplish. But what we do claim for hydrocyanic acid gas is that provided the conditions of the house are proper there is no other insecticide on the market to equal it for efficiency and safety. *Jas. Fulton.*

STATE FRUIT FARMS.—There has been a good deal of discussion on the subject of the necessity for improvement in our methods of agriculture and horticulture, but up to the present very little has been done by the State in this direction. The paucity and poor quality of English-grown fruit has also been much bewailed; and I should like to make a suggestion in this direction, which might be taken up with advantage by the Board of Agriculture. It is that the Government should institute in some of the leading fruit-growing counties (Kent, Gloucestershire, Herefordshire, and Devonshire) small stations of about twenty-five acres, to be laid out in sections for the experimental growing of different kinds of fruit. Each station should be placed in the charge of an expert in culture, and systematic planting, pruning, eradication and prevention of pests, manuring and cropping, could be demonstrated in the case of each kind of fruit. The stations should be open at all times to inspection and examination by those wishing to learn, and would provide valuable centres for the dissemination of knowledge. Half-a-dozen such centres, even if the land were acquired by purchase, would not be expensive; they would be welcomed by those who required guidance in the growing of fruit, and if well managed might be the means of checking the import of foreign fruit, a great cause of which is the inferior quality of that at present grown in England. *E. Molyneux.*

THE N.E.H.S.—I am very pleased to see Mr. Jackson's contradiction of my statements, for this serves my purpose admirably and makes me bring forward some of the facts. I feel sure the Council is unaware of how in committee things go on which are not to the welfare of the society. (1) A lecture was arranged to be delivered at York by Dr. Russell, of Rothamsted. About a score of persons attended! This was simply due to the lecture being given on the very night of the annual meeting of the York Florists' Society. A little tact and a little of that spirit of co-operation which is so lacking would have enabled local gardeners and amateurs to attend the lecture. (2) On October 22 the then secretary of the Northern Fruit Congress was requested to see the Hexham local committee and talk over a scheme of co-operation, if not amalgamation. While the negotiations were proceeding satisfactorily matters were completely taken out of the secretary's hands; new negotiations

arranged with the inevitable result—the union movement was nullified. This surely is lack of courtesy and tact. (3) As to there being no policy of isolation, I ask who prevented the then so-called editor of the N.E.H.S. *Journal* from publishing an editorial last year advocating "co-operation" among northern societies? I refrain from giving more of these incidents, for the reason that only from a sense of duty to others have I entered on this (to me) rather unpleasant criticism of the N.E.H.S. If Mr. Jackson will publish the attendances of the council and committees of the last six months it will soon be seen how it is that there is such a Leeds bias. The N.E.H.S. is too good a thing, and many of us have spent too much money and time in trying to make it a good thing, to be spoilt by what I must call a little and a local policy. *J. Bernard Hall.*

RAINFALL.—The rainfall in these gardens during February amounted to 4.20 inches, and there were 18 rainy days. During March 5.02 inches fell on 25 days. In March, 1913, the rainfall amounted to 5.02 inches, and there were 25 wet days. Garden and farm work has been much delayed in consequence of the wet spring. *G. S., Hartland Abbey, Devonshire.*

—The following record of the rainfall in the months of January, February and March for the past three years may be of interest to your readers. 1912:—January 2.81 inches on 14 days, February 2.35 inches on 17 days, March 4.41 inches on 19 days. The total rainfall was 9.57 inches, and the number of wet days 50. 1913:—January 4.73 inches on 21 days, February 1.23 inches on 11 days, March 4.98 inches on 15 days. Total rainfall 10.94 inches, and 47 rainy days. 1914:—January .72 inch on 10 days, February 4.62 inches on 16 days, March 5.16 inches on 25 days. Total rainfall 10.50 inches, registered on 51 rainy days. *Thos. Tyson, Wykehurst Park Gardens, Haywards Heath.*

—Our rainfall for February was 10.95 inches, but the amount is not a record for this district. In March, 1913, the fall totalled 10.43 inches; in August, 1912, 11.89 inches; in December, 1912, 11.26 inches; and in March, 1912, 10.53 inches. In March of the present year the amount recorded was 7.52 inches. Our records for the past two years may be interesting. (The rain gauge is 700 feet above sea level. Latitude, 51° 44' 45" N.; longitude, 309' W.)

Lewis E. Bailey, Parks Superintendent, Abertillery, Monmouthshire.

JOURNEYMAN GARDENERS' WAGES.—I fully agree with Mr. T. Smith (p. 224) that gardeners are born, not made. The further statement that all who are so born are, like cream, bound to get to the top, will need further explanation. The point is, what does Mr. Smith mean by the top? Does he consider that all men who are to-day working with no consideration of hours, and are not sparing themselves in any way, who are undoubtedly "born gardeners," are at the top, or have any prospects of reaching the top in the near future? Mr. Smith's reference to cream brought to my mind the fact that in many modern dairies a separator is used. I am not a member of the B.G.A. and therefore cannot take up the cudgels on its behalf, but if I may be allowed to make a suggestion, I should advocate that the B.G.A. act as a separator, so far as possible, by accepting only born gardeners as members, and certainly not the aspiring young men so aptly described in Mr. Smith's note. *Roamer.*

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 7.—The exhibition, on the occasion of the fortnightly meeting held in the Vincent Square Hall, Westminster, on Tuesday last, again filled the whole of the building. Orchid lovers found much to admire in the many excellent groups of these flowers, and numerous novelties were submitted for Awards, two receiving 1st Class Certificates and three Awards of Merit from the Orchid Committee.

The Floral Committee recommended one 1st Class Certificate and eight Awards of Merit to new plants, whilst twenty-three groups were awarded Medals.

The Narcissus Committee recommended seven Awards of Merit to novelties, and eight collections were awarded Medals.

The only exhibit of importance in the Fruit and Vegetable Section was a collection of vegetables staged by Messrs. SUTTON AND SONS.

At the three o'clock meeting in the Lecture Room, Mr. C. R. FIELDER delivered an address on "The Cultivation of Amaryllis."

Floral Committee.

Present: H. B. May, Esq. (in the chair), Messrs. C. T. Drury, W. J. Bean, C. E. Pearson, C. E. Shea, W. H. Morter, Wm. Howe, J. W. Moorman, George Gordon, John Green, W. P. Thomson, A. Turner, Chas. Dixon, John Dickson, W. Bain, Thomas Stevenson, J. Jennings, J. F. McLeod, W. H. Page, F. W. Harvey, W. Cuthbertson, C. R. Fielder, Jas. Hudson, J. T. Bennett-Poë, E. H. Jenkins, Geo. Paul, R. C. Notcutt and E. A. Bowles.

AWARDS.

FIRST-CLASS CERTIFICATE.

Clematis Armandii (see fig. 113).—An evergreen, Chinese species, remarkable for its handsome foliage, as much as for its profuse trusses of white flowers. The leaves are ternate, glossy, leathery, with three deep-veined veins 6 inches long. The flowers are borne in dense, axillary clusters, each stalk branching and bearing three flowers 2 to 2½ inches in diameter and composed of six to eight segments. It seems closely allied to *C. indivisa*, and it is hoped that it will prove hardy in this country. The flowering specimen shown had received the protection of a cold house. Shown by Hon. V. GIBBS, Aldenham (gr. Mr. E. Beckett). The species was first figured in *Gard. Chron.*, July 8, 1905, as a Supplementary Plate.

AWARDS OF MERIT.

Prunus Blicricana fl. pl.—This is the best double form of *Prunus cerasifera atropurpurea* (*P. Pissartii*). The foliage is prettily tinted, even deeper in shade than the type. The flowers are 1½ inch in diameter, almost peach-pink in colour and semi-double. The vigorous growths shown were covered with flowers, and the plant promises to be an excellent addition to hardy shrubs. It is an improvement both in size and colour of flower on the variety known as *P. Moseri fl. pl.* Shown by Mr. R. C. NOTCUTT.

Osmanthus Delavayi.—This beautiful shrub is a valuable acquisition from China. It bears small, dark evergreen glabrous foliage, ovate in shape with serrate edge, ½ to ¾ inch in length by ¼ to ½ inch in breadth. Its great beauty, however, lies in the dense, axillary clusters of white, fragrant flowers, which are as long as the leaves, and therefore more showy than in the coarser species. They often number twelve or more in a cluster, and as these are in opposite pairs the flowers have the appearance of being in whorls. The plant shown was 18 inches high, and had been protected by a cold frame, but it is hoped that the species will prove hardy. Shown by Hon. V. GIBBS.

Columnea major glabra.—A handsome, scarlet-flowered stove plant with arching growths, which make it an admirable basket plant. The stems are stout and fleshy; the leaves thick, glossy, ovate-lanceolate in shape, and about 1½ inch in length by ½ inch in breadth. The flowers are 3 inches long, borne singly in the axils of the upper leaves to form a raceme-like cluster; they twist round on their stalks to face upwards and spread showily from the horizontal or hanging stems.

Anthurium conchiflorum.—A showy hybrid between *A. Scherzerianum* and *A. Chamberlain-*

ianum, with the intense self-scarlet spathe with glossy reverse and twisted spadix of the former species, but the spathe is much larger and broader, and is hollowed out to a shell or saucer-like shape. The foliage is large and handsome, the leaf blade being a foot in length by 5 inches in width. These two were shown by ELIZABETH LADY LAWRENCE (gr. Mr. W. Bain).

Auricula Gordon Douglas.—This is a good addition to the fancy varieties. The colour is a warm yellow, a shade of buff or orange suffusing the margin of each segment. The pip is flat, round and even, and a perfectly-formed disc of pure white meal surrounds the small eye.

Primula Bookham Gem.—From the florist's point of view, this is perhaps the best of the *viscosa* × *Auricula* crosses. The flowers are deep violet-purple, 1½ inch in diameter, with full, overlapping, broad segments and small, white eye. It was shown with the variety Mrs. James Douglas, which was given an award last year, but the flower of Bookham Gem is larger, deeper in colour, and neater in the round, white eye. The foliage is pale-green, downy, slightly serrated in the upper half, and bold in growth. These two were shown by Mr. JAS. DOUGLAS, Great Bookham.

Rose Constance.—In its rich yellow this beautiful Pernetiana hybrid at once challenges comparison with Rayon d'Or. It is not inferior in colour and has the same tinting of crimson on the outer petals. In habit and form it is a great advance. Blooms on 2 feet stems from pot plants were shown; the buds are finely pointed and free from the shallowness which spoils Rayon d'Or as an exhibition variety. The foliage is firm and the growths spiny, whilst the blooms possess a fine fragrance, reminding one of the Teas. Shown by Mr. H. BECKWITH, Hoddesdon.

Rhododendron fastigiatum.—This is a dwarf alpine Chinese Rhododendron allied to *R. intricatum* and *R. violaceum*. It has the same open flowers and spreading stamens as the latter, but is of a purer blue, expands perhaps a little less flat, and is rather smaller, being an inch across. In habit it is one of the dwarfiest, the 4-inch high plant shown being branched and carrying several trusses of from 3 to 5 flowers. The leaves are closely crowded, overlapping in a tile-like arrangement. They are ovate in shape and covered with rusty dots, and vary in length from ½ to 1 inch, and in breadth from ¼ to ½ inch. Shown by Mr. REUTHE, Keston.

OTHER NOTEWORTHY PLANTS.

Syringa pinnatifolia is a pretty, white Chinese Lilac. The axillary flower-trusses are neither very large nor showy, but the foliage is elegantly cut into four or five pairs of small, glabrous, bright-green leaflets, each about ½ inch in length by ¼ inch in breadth, which makes the plant a very graceful addition to a valuable flowering group. Shown by Hon. V. GIBBS.

Clematis montana superba, exhibited by Messrs. JACKMAN, is a very large-flowered form of the type.

Agapetes macrantha, a rare Indian shrubby evergreen, was given a First-class Certificate in 1860. A handsome spray of the curious ribbed flowers, marbled pink and crimson, was shown by W. MAPPIN, Esq., Sheffield.

Primula Listeri, which has the reputation of being the non-poisonous ally of *P. obconica*, was shown by Miss WILLMOTT.

MISCELLANEOUS EXHIBITS.

Col. MARK LOCKWOOD, M.P., B'shop's Hall, Romford (gr. Mr. J. Craddock), was awarded a Silver-gilt Lindley Medal for standard Gardenias. The plants attracted attention by reason of their fine culture, each being a very healthy specimen some 6 feet tall, and bearing plenty of flowers and unopened buds.

Messrs. R. and G. CUTHBERT, Southgate, had the largest individual exhibit, in a collection of forced shrubs. (Silver Flora Medal.)

Messrs. H. B. MAY AND SONS, Edmonton, had a mixed exhibit of flowering plants, including Hydrangeas, the blue-flowered varieties being uncommonly good. (Silver Banksian Medal.)

Messrs. JAMES VEITCH AND SONS, Chelsea, were awarded a Silver Flora Medal for Azaleas, Boronias, Hippeastrums and pans of Alpines.

Messrs. W. CUTBUSH AND SONS, Highgate, showed Roses and Carnations, in addition to their exhibit of Alpines. (Silver Flora Medal.)

Mr. JAMES DOUGLAS, Great Bookham, showed exceptionally fine Auriculas. Each plant was a splendid specimen and the varieties some of the finest in existence. A selection includes Canary Bird, gold with a rim of white paste; Vincent Douglas, purple with cream centre; Mrs. Gardiner, puce with white mealy rim; Lady Veitch, old-rose colour; Harrison Weir and the beautiful new Gordon Douglas, which received an Award of Merit.

Bunches of Zonal-leaved Pelargoniums were displayed by Messrs. H. J. JONES, LTD., Hither Green, Lewisham (Bronze Banksian Medal); and Messrs. H. CANNEL AND SONS, Eynsford.

Mr. PHILIP LADDS, Swanley, Kent, was awarded a Bronze Banksian Medal for a small collection of popular greenhouse flowers.

Messrs. WILLS AND SEGAR, South Kensington, showed an exhibit, as at the last meeting, of Azaleas, Mignonette, Cyclamens, Heaths, and Boronias.

Mr. L. R. RUSSELL, Richmond, showed the scarlet *Clianthus puniceus* finely in a collection of other flowers and ornamental Ivies. (Bronze Flora Medal.)

Mr. GEO. PRINCE, Oxford, exhibited Roses, for which a Silver Flora Medal was awarded.

There were many beautiful exhibits of Perpetual-flowering Carnations, the exhibitors being Mr. C. ENGELMANN, Saffron Walden (Silver Banksian Medal); Mr. H. BURNETT, Guernsey, Silver-Gilt Flora Medal; Messrs. STUART LOW AND CO., Enfield (Silver Banksian Medal); Mr. J. C. JENNER, Rayleigh, Essex (Bronze Banksian Medal); Messrs. W. WELLS AND CO., LTD., Merstham; Messrs. YOUNG AND CO., Hatherley (Bronze Flora Medal); and Messrs. ALLWOOD BROS., Wivelsfield, Haywards Heath, whose fine blooms of Lady Millar, a perpetual-flowering variety of the Malmaison type, were much admired. (Silver Banksian Medal.)

Messrs. A. H. COLE, LTD., Swanley, again showed their strain of the pretty Star Cinerarias.

Messrs. JARMAN AND CO., Chard, staged a floor group of Star Cinerarias.

Messrs. CARTER PAGE AND CO., London Wall, again showed a collection of Violas, and the beautiful clear blue *Nemophila insignis*.

Rhododendrons in variety and of fine quality were shown by Messrs. R. GILL AND SONS, Falmouth. (Silver Banksian Medal.)

Messrs. PHILLIPS AND TAYLOR, Bracknell, Berkshire, had a large patch of the beautiful *Primula rosea* in a mixed collection of spring flowers.

Messrs. BLACKMORE AND LANGDON, Twerton-on-Avon, Bath, showed a fine strain of Polyanthus in batches of yellow, crimson, white and mixed varieties.

Messrs. GEO. JACKMAN AND SON, Woking, introduced sprays of flowering Apples and Peaches at the back of their choice exhibit of hardy flowers.

Other exhibitors of hardy flowers were Messrs. BAKERS, Wolverhampton; Mr. G. MILLER, Wisbech; Mr. VERNON T. HILL, Langford, near Bristol, whose Polyanthus were very good; THE BURTON HARDY PLANT NURSERY; Messrs. W. CUTBUSH AND SON, Highgate; Messrs. G. and A. CLARK, LTD., Dover; GUILDFORD HARDY PLANT NURSERY; Mr. G. REUTHE, Keston, Kent. Mr. REUTHE also displayed flowering shrubs, including *Viburnum Carlesii*, with fragrant, pink-tipped flowers. (Bronze Flora Medal.)

Messrs. J. PITER AND SONS, Bayswater, again carried off the palm amongst the rock-garden exhibits, receiving a Silver-gilt Banksian Medal for an excellent display. There was a large pool at one end, and this was grouped about with Primulas, clumps of Daffodils, and other flowers. The Genus *Primula* was well represented in escarpments and on bluffs of the rockery. A notable feature was a batch of the Alpine Wall-flower—*Matthiola fenestralis*.

Mr. JAMES BOX, Haywards Heath, Sussex, filled the east corner of the hall with a large rock garden of excellent design, the back having large clumps of Rhododendron Pink Pearl, Magnolia Soulangiana, and other flowering shrubs. The clear blue *Omphalodes cornifolia* (*cappadocica*) was a conspicuous object amongst the rockwork. (Silver Banksian Medal.)

Mr. MATRICE PRICHARD, Christchurch, had a dainty rockery, well furnished with a variety of beautiful alpines. (Silver Banksian Medal.)

Messrs. T. S. WARE, LTD., Feltham, also utilised a rockery, on which to display alpines, the masses of *Aubrietia* Lloyd Edwards and *Primula frondosa* being very striking. (Bronze Flora Medal.)

Rock gardens were also shown by Messrs. BARR AND SONS, King Street, Covent Garden; Messrs. J. CHEAL AND SONS, Crawley; Messrs. THOMPSON AND CHARMAN, Bushey, Hertfordshire; Mr. CLARENCE ELLIOTT, Stevenage; Messrs. JOHN WATERER, SONS, AND CRISP, LTD., Twyford; the Misses HOPKINS, Shepperton; Messrs. WHITELEGG AND PAGE, Chislehurst (Bronze Banksian Medal); and Messrs. R. TUCKER AND SONS, Oxford.

Messrs. REAMSBOTTOM AND CO., Geashill, Ireland, displayed vases of their fine St. Brigid Anemones, which were awarded a Bronze Flora Medal.

Orchid Committee.

Present:—J. Gurney Fowler, Esq., in the chair, and Messrs. Jas. O'Brien (hon. secretary), H. J. Chapman, F. Sander, R. G. Thwaites, F. J. Hanbury, F. M. Ogilvie, T. Armstrong, A. McBean, J. Charlesworth, J. Cypher, W. H. Hatcher, H. G. Alexander, A. Dye, E. H. Davidson, W. H. White, W. Bolton, Gurney Wilson, R. A. Rolfe, and Sir Harry J. Veitch.

AWARDS.

FIRST-CLASS CERTIFICATES.

Odontoglossum Mogul (*Oakwoodense* × *ardentissimum*), from Lieut.-Col. Sir Geo. L. HOLFORD, K.C.V.O. One of the most beautiful of hybrid *Odontoglossums*; perfect in shape and unique in colouring. The flowers had equally broad segments, three-fourths occupied by a large, irregular claret-purple blotch, the margins being clear white, the petals and lip fringed. The white of the outer parts of the segments is in effective contrast with the dark inner zone.

Cattleya Titius Shrubby variety (*Enid* × *Octave Doin*), from F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth). This beautiful variety, which received an Award of Merit at a former meeting, has developed into one of the largest and best *Cattleyas*. The large, broad flowers had the sepals and crimped petals white, with a pearl-pink tint; the fine labellum rose-purple in front, and with a yellow disc.

AWARDS OF MERIT.

Laelio-Cattleya amabilis Fascinator (*L. C. Fascinator albens* × *C. Ludemanniana Stanleyi*), from Messrs. CHARLESWORTH AND CO. A really charming hybrid, and quite distinct. Sepals and petals pure white, lip deep claret-red, the front finely expanded.

Odontioda Clive (*parentage unrecorded*), from Mrs. NORMAN COOKSON, Oakwood, Wylam (gr. Mr. H. J. Chapman). A flower of good size and shape, the dark colour suggesting *Odontoglossum Vuylstekei*. Sepals dark red-purple; the broader petals similarly coloured, but with a white margin. Lip with dark purple blotches.

Odontioda Graivrea splendens (*Odontoglossum Rossii* × *Cochlidium Nozthiana*) from M. GRAIRE, Amiens. In habit this closely resembles *O. Rossii*, but the inflorescence has more flowers. Sepals and petals blotched with orange-red; lip light rose with yellow crest.

CULTURAL COMMENDATION.

To Mr. H. G. ALEXANDER, Orchid-grower to Lieut.-Col. Sir Geo. L. Holford, K.C.V.O., for a grand specimen of *Laelio-Cattleya Tigris* (*L. Cowanii* × *L. C. Dominiana*), with two spikes of many bright yellow flowers, with red markings on the lip.

GENERAL EXHIBITS.

Mrs. NORMAN C. COOKSON, Oakwood, Wylam (gr. Mr. H. J. Chapman), showed a group of hybrid *Odontiodas* and *Odontoglossums* raised at Oakwood. The choicest were *Odontioda Sibyl*, claret-red with light markings; *O. Arthur* (*Bradshawiae* × *percultum*), the yellow ground colour prettily marked with red; and *O. Oakwoodiense Futurist* (*percultum* × *Bradshawiae* Oakwood variety), white spotted with red, and with a broad violet margin. Among the many seedling *Odontoglossums* *O. crispum Phoebe*, almost wholly dark claret colour, was the most remarkable. (Silver Flora Medal.)

Lieut.-Col. Sir Geo. HOLFORD, K.C.V.O., Westonbirt (gr. Mr. H. G. Alexander), staged a select group of typical Westonbirt quality, and comprising two specimens of the beautiful *Cattleya Schröderae* The Baron, *Cattleya Magnat* (*Mossiae* × *Whitei*), *Sophr.-Laelio-Cattleya Sunloch* (*L. C. Goldfinch* × *S. L. C. Danae*), reddish-orange, with rose veining, a grand specimen of the true *Cymbidium Parishii* *Sanderae*, with two spikes of bluish-white flowers with ruby spotting on the lip; the superb *Brasso-Cattleya The King*, which was such an attraction at the Chelsea International Exhibition, and various other good *Brasso-Cattleyas*. (Silver Flora Medal.)

Sir JEREMIAH COLMAN, Bart., Gatton Park, Surrey (gr. Mr. Collier), staged an interesting group in which were noted *Odontioda Vuylstekeae* *Gattonense*, *Odontoglossum Pesca-torei* album, of a clear white, with yellow crest; a charming plant of the red *Polystachya paniculata*, with four spikes; *Coelogyne Sanderae*, *Masdevallia Arminii*, *Pleione yunnanense* and *Brasso-Cattleyas*.

Messrs. CHARLESWORTH AND CO., Haywards Heath, staged a group of finely-grown Orchids, which included a dark form of their new *Odontioda Brewii*, *Miltonia Hyeana*, with a prettily-veined light rose lip, a dark form of *Phaius simulans*, *Laelio-Cattleya Percy* Scott, with striped flowers, of unusual colour, and other *Laelio-Cattleyas*, the finest being the new *L. C. amabilis Fascinator* (*L. C. Fascinator albens* × *C. Ludemanniana Stanleyi*), one of the best of its section. (Silver Flora Medal.)

Messrs. SANDER AND SONS, St. Albans, had a very effective group of good *Odontoglossums*, *Laelio-Cattleyas*, *Odontiodas*, and other Orchids. A plant of *Lycaste Skinneri* alba bore seven large white flowers; there were also the white *Cattleya Susannae* Hye de Crom, some fine *C. Schröderae*, *C. Parthenia* Prince of Wales, *Coelogyne Lawrenceana*, *Cymbidium amabilis* (*Lowii-Mastersii* × *insigne*), and other good *Cymbidiums*, *Dendrobium thyrstiflorum*, *D. aggregatum* and *Miltonia Bleuana*. (Silver Flora Medal.)

Messrs. STUART LOW AND CO., Bush Hill Park, Enfield, staged a fine group, in which *Dendrobiums* were prominent, *D. Brymerianum*, *D. Jamesianum*, and *D. Wardianum* being specially fine. The varieties of *Cattleya Schröderae* included a good pure white form; *Oncidium sarco-des* and other *Oncidiums* were well represented, and *Brasso-Cattleyas*, *Cymbidiums*, *Odontiodas* and *Odontoglossums* were shown well. (Silver Flora Medal.)

R. G. THWAITES, Esq., Chessington, Streatham, showed a small selection of hybrid *Odontoglossums* and *Dendrobiums*, together with a plant of *Sophr.-Cattleya Thwaitesii* with pretty red flower. (Silver Banksian Medal.)

Messrs. JAS. CYPHER AND SONS, Cheltenham, staged a group, in which a fine plant of *Phaius tuberculatus*, *Dendrobium Cambridgeanum* and other *Dendrobiums*, including the rare white and violet *D. superbum* *Huttonii*, some pretty *Odontoglossums*, and *Arpophyllum giganteum* were noted. (Silver Banksian Medal.)

J. T. BENNETT-POE, Esq., Holmwood, Chess-hunt (gr. Mr. Downes), showed *Cymbidium Lowianum* *Holmwood* variety, *C. L. Bennett-Poe's* variety, and *Brasso-Cattleya Digbyano-Warszewiczii*, all of good quality.

PANTIA RALLI, Esq., Ashted Park, Surrey, exhibited *Odontioda Vuylstekeae*, and *Brasso-Cattleya Digbyano-Schröderae*.

Messrs. HASSALL AND CO., Southgate, staged a pleasing group, in which were several plants of *Laelio-Cattleya G. S. Ball*, whilst on either of these were fine *Cattleya Schröderae* and the pretty white *Brasso-Cattleya Menda*.

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford, showed three fine plants of the rich yellow *Dendrobium Thwaitesiae* Veitch's variety.

Major LISTER, Warninglid Grange, Haywards Heath (gr. Mr. Johnson), showed a plant of the singular *Gongora quinquerivis*.

EUSTACE F. CLARK, Esq., Evershot, Dorset, sent a flower of *Laelio-Cattleya* (*C. Trianae* × *L. Boothiana*), and an *Odontioda*.

Mrs. MEADE-KING, Seven Elms, Druid Stoke, Bristol, sent for name *Schomburgkia Ludemannii* illustrated in the *Botanical Magazine*, t. 8427; the species is closely allied to *S. undulata*.

Narcissus and Tulip Committee.

Present: E. A. Bowles, Esq., in the chair, Miss E. Willmott, Rev. Joseph Jacob, Messrs. J. T. Bennett-Poe, Arthur Goodwin, H. V. Warrender, G. W. Leak, J. D. Pearson, P. D. Williams, W. Goldring, C. S. Dickins, P. Rudolph Barr, Herbert Smith, W. A. Watts, W. A. Milner, C. Lemesle Adams, Christopher Bourne, W. F. M. Copeland, F. Herbert Chapman, H. Backhouse, Wm. Poupart, and Chas. H. Curtis (hon. secretary).

AWARDS OF MERIT.

Narcissus Tantalus (suitable for cutting).—A giant *Leedsii* variety, with a corona as large as in some Trumpet varieties. The white perianth segments are nearly pure white, of good substance, and setting off the long, tubular, soft yellow corona, which is daintily frilled. Shown by Mr. W. A. WATTS.

N. Inglescombe (suitable for cutting).—This exceedingly decorative double *Daffodil* is of large size, of a pleasing medium shade of yellow, and the blooms are well disposed on stout stalks.

Crocus (garden).—A splendid large *Incomparabilis* variety, in which the orange-yellow corona glows with bright colour, and contrasts finely with the pale yellow-coloured perianth; the blooms are carried on long, stout stalks. This and the foregoing was shown by Mr. ALEX. M. WILSON.

N. Ivorine (show).—This medium-sized *Leedsii* variety possesses good colouring. The perianth segments are ivory-white, and the flattish coronas is of a very pale yellow shade of colour.

Royal Sovereign (show).—A rather more than semi-double *Daffodil*, giving the impression of a *Leedsii* flower which has endeavoured to produce three coronas and half a dozen extra perianth segments in place of the normal corona. It is a rather novel form, which would have a certain decorative value. These two varieties were shown by Messrs. CARTWRIGHT AND GOODWIN.

White Maximus (show).—Although the blooms are not quite white, they are sufficiently so to justify the name. The colour is a very deep cream or the palest sulphur-yellow, and the blooms have all the merits of the well-known type. Shown by Messrs. WALTER T. WARE, LTD.

Queen Primrose (show).—A Trumpet variety which bears the blooms at right angles to the stalks. The perianth segments are pale primrose in colour, and the widely-expanded trumpet is sulphur-yellow. Shown by Mr. H. W. PHILLIPS.

GENERAL EXHIBITS.

Messrs. BARR AND SONS, Covent Garden, London, filled a goodly space with many admirable blooms. Of the newest sorts *Carmenta*, a giant *Leedsii*, with white perianth segments and pale yellow corona, and *Justicia*, a splendid rich yellow Trumpet variety, were especially noteworthy. (Silver-gilt Flora Medal.)

Messrs. R. H. BATH, LTD., Wisbech, specialised in magnificent Darwin Tulips growing in bowls of fibre. The best market sorts were represented, and many good *Daffodils* were also shown. (Silver-gilt Flora Medal.)

Mr. ALEX. M. WILSON, Shovel, Bridgwater, gave his new variety *Crocus*, which received an Award of Merit, the place of honour in an admirable collection. *Dragoon* and *Gadfly* also attracted much admiration. (Silver-gilt Flora Medal.)

Mr. C. BOURNE, Simpson, Bletchley, staged a very representative collection of *Daffodils* as well as good Darwin Tulips. (Silver-gilt Banksian Medal.)

Messrs. SUTTON AND SONS, Reading, illustrated in an admirable manner the decorative value of the standard varieties of *Narcissus*. (Silver-gilt Banksian Medal.)

Mr. HERBERT CHAPMAN, Rye, Sussex, had a noteworthy collection of *Narcissus* blooms in the annex, which included enormous blooms of *Van Waveren's* Giant. (Silver Flora Medal.)

Messrs. CARTWRIGHT AND GOODWIN, Kidderminster, arranged a small but select set of cut blooms, including several promising unnamed seedlings. (Silver Banksian Medal.)

Messrs. WALTER T. WARE, Bath, in addition to *White Maximus*, showed other excellent

Trumpet varieties, and several bright-eyed Barrii blooms. (Silver Banksian Medal.)

Messrs. CARTER AND CO., Raynes Park, had a very decorative exhibit; Mr. W. A. WATTS, St. Asaph, staged a collection of Welsh-grown Daffodils; Messrs. R. SYDENHAM, LTD., Birmingham, contributed cut Daffodils and Lily-of-the-Valley growing in vases of fibre; and the Rev. G. ENGLEHEART, Dinton, Salisbury, showed a selection of unnamed seedling Daffodils, in which excellent Trumpet varieties predominated.

Fruit and Vegetable Committee.

Messrs. SUTTON AND SONS, Reading, were awarded a Silver-gilt Knightian Medal for a collection of vegetables, including splendid heads of Superb Early White Broccoli, Pride of the Market Cucumbers, Golden Ball Lettuces, and Princess of Wales climbing French Beans.

Messrs. J. CHEAL AND SONS, Crawley, showed varieties of Apples, including the new Crawley Beauty.

CORNWALL DAFFODIL AND SPRING FLOWER.

MARCH 31.—This society, of which Her Majesty Queen Mary and Her Majesty Queen Alexandra are patronesses, opened its eighteenth annual show at this early date in the great Market Hall, Truro. The arrangements were, as usual, admirably carried out under the supervision of the Hon. John Boscawen, who has been hon. secretary of the society ever since it was founded. Owing to the extreme lateness of the season it was a difficult matter to procure some of the spring flowers, Erythroniums, which are usually in full bloom at this time, being as yet unopened. However, an excellent display was provided in every section of the show.

In the leading Daffodil class, that for 24 varieties of Daffodil in commerce or not in commerce, Mr. J. C. WILLIAMS again won the 1st prize, with a splendid collection of mostly unnamed seedlings. On his stand were Croesus, with primrose perianth and wide, saucer-shaped orange cup, Mrs. Robert Sydenham, white trumpet, and the others were unnamed. The class for a collection of 24 varieties of Daffodils in commerce attracted several entries. The 1st prize was won by Miss CLARICE VIVIAN, who staged fine flowers, including those of the varieties Lord Roberts, King Alfred, Duke of Bedford, Hamlet, Tennyson, Bullfinch and Horace. For 9 distinct varieties of Trumpet Daffodils, the 1st prize was won by Mr. A. BLENKINSOP, the blooms of King Alfred and Cornelia being very good. For 6 varieties of *N. incomparabilis*, the 1st prize was won by Miss CLARICE VIVIAN, whose best blooms were Autocrat, Pilgrim and Brigadier.

Lady MARGARET BOSCAWEN excelled in the class for 6 varieties of the Barrii section with Albatross, Blood Orange, Oriflamme and Incognita on her stand, which was exceptionally good. For 6 varieties of *N. Leedsii* the 1st prize was awarded to Mr. A. BLENKINSOP, White Queen and Janet Image being exceptionally good. In the classes for the finest blooms in commerce the 1st prize for the best Trumpet Daffodil was won with Lord Roberts by Miss CLARICE VIVIAN, who also showed the finest *incomparabilis* bloom in Victory. Mr. H. G. HAWKER had the best Barrii variety in Sunrise, whilst the finest *Leedsii* was Miss Mary, shown by Miss VIVIAN, who also excelled in the class for a Poeticus variety. For varieties not in commerce the 1st prize for Trumpet Daffodils was won by Mr. P. D. WILLIAMS.

OTHER FLOWERS

For three bunches of Anemones and one bunch of *Anemone fulgens* Mrs. R. BARCLAY FOX won the 1st prize. For Primula species in 3 varieties equal 1st prizes were awarded to Mr. E. J. P. MAGOR and Mr. P. D. WILLIAMS. For 12 spring flowers the 1st prize was won by Mr. P. D. WILLIAMS with *Scilla italica alba*, *Ourisia macrophylla*, *Caltha platypetala*, *Ornithogalum nutans*, Muscari Heavenly Blue, Fritillaria Thumbergii, Ficaria grandiflora, Tulipa Fosteriana, Muscari moschatum, Epimedium sulphureum, Iris bucharica, and *Anemone blanda rosea*. For 6 spring flowers the 1st prize was won by Lady MARGARET BOSCAWEN, who showed *Anemone fulgens*, Wall-

flowers, Tulips, *Caltha platypetala*, Muscari Heavenly Blue and *Iris tuberosa*. The best miniature rock-garden was exhibited by Miss G. WATERER, who showed several Saxifrages, Violas and Primulas. In the classes for Rhododendrons 1st prizes were won by Mr. J. C. WILLIAMS, Mr. R. BARCLAY FOX, Mr. O. H. SHILSON and Mr. J. C. DAUBUZ. The 1st prize for 6 Camellias grown in the open was won by Mr. J. C. WILLIAMS, whilst for 6 Camellias grown under glass the 1st prize was awarded to Mr. J. C. DAUBUZ. One of the most attractive exhibits in the show was a collection of hardwood plants in pots. These were raised from seeds sent from Yunnan, China, in 1911 by Mr. Forrest. Plants of a form of *Rhododendron racemosum* were in splendid flower, as were several plants of *R. oleifolium*. Others were *R. intricatum*, with lavender-blue flowers, *R. rigidum*, and an unnamed species with purple flowers: and there

NON-COMPETITIVE EXHIBITS.

Messrs. BARR AND SONS, King Street, Covent Garden, exhibited a collection of Daffodils, including several new seedlings. THE DEVON ROSERY, Torquay, had a very pretty stand with flowering shrubs and Roses. Messrs. VEITCH AND SON, Exeter, staged *Eutaxia myrtifolia*, *Grevillea sulphurea*, *G. alpestris*, *G. Priessii*, *Burchellia capensis* and other choice flowering shrubs. Mr. G. REUTHE, Keston, showed a selection of Alpines. Mr. J. C. MARTIN exhibited some very interesting Daffodils, amongst which were Silver Chimes, Rockery Gem, Sea King, Iron Duke, Artificier, Searchlight, Great Dane and Frost Cave. Messrs. ALLWOOD BROS., Haywards Heath, showed Carnations. Messrs. JOHN PIPER AND SONS., Bayswater, showed a collection of Primulas. Messrs. TRESEDER AND CO., Truro, staged Tree Ferns, *Senecio Greyi*, *Acacia Drummondii*, *Forsythia aurea variegata*, Pitto-

FIG. 113.—CLEMATIS ARMANDII: FLOWERS WHITE.
(R.H.S. 1st class certificate on Tuesday last; see p. 257.)

was also a new Photinia. The collection was exhibited by Mr. J. C. WILLIAMS, and was awarded the 1st prize. For three vases of outdoor Acacias the 1st prize was won by Sir A. P. VIVIAN, for an unknown species, *A. Riceana* and *A. melanoxylon*. The Rev. A. T. BOSCAWEN excelled in the class for 20 varieties of hardwood flowering shrubs and climbers, with *Euphorbia mellifera*, *Magnolia stellata*, *Pernettya ciliaris*, *Acacia diffusa*, *Correa speciosa picta*, *Clematis indivisa lobata*, *Euphorbia Wulfenii*, *Eriostemon nerriifolium*, *Grevillea sulphurea*, *Agonis parviceps*, *Chorizema Lowii*, *Anopterus glandulosus*, *Correa speciosa bicolor*, *Correa speciosa Harrisii*, *Veronica macrocarpa*, *Erica australis*, *Ceanothus rigidus*, *Cytisus proliferus*, *Prostanthera rotundifolia* and *Corylopsis* variety. In the smaller class for 6 of the same kind the 1st prize was won by Rev. A. T. BOSCAWEN.

AWARDS.

A Premier Award was given to Mr. J. C. WILLIAMS for the group of Chinese Rhododendrons already mentioned. To Mr. WALTER WARE, Bath, for Daffodil Queen of the West. An Award of Merit to Mr. P. D. WILLIAMS, for Daffodil Ivoryine. To Mr. J. C. MARTIN, Truro, for Daffodil Silver Chimes. To Messrs. BARR, for Daffodil Boreas. To Messrs. ALLWOOD BROS., for Carnation Mary Allwood. To Mr. G. REUTHE, for Primula Julae. To Rev. A. T. BOSCAWEN, for *Correa speciosa Harrisii*. To Messrs. VEITCH AND SON, for *Grevillea longifolia*. To Mrs. POWYS ROGERS, for *Clivia citrina aurea*, and to Mr. PERCY WATERER, for *Isopogon latifolius*.

sporum tenuifolium and *Eucalyptus Beauchampiana*.

LIVERPOOL HORTICULTURAL.

APRIL 1 and 2.—This society held its twentieth spring show in the local Corn Exchange on these dates. The exhibition proved a success, and from a decorative point of view was especially good. In the class for pots or pans of hardy herbaceous and four bulbous plants there were three exhibitors, and the 1st prize was won by W. J. LOCKETT, Esq., Aigburth (gr. Mr. E. R. Finch); 2nd, W. TOD, Esq., Dry Grange, Allerton (gr. Mr. G. Eaton); 3rd, T. WOODSEND, Esq., Cleveley, Allerton (gr. Mr. H. Osborne). The best twelve Hyacinths, distinct, were shown by ARTHUR EARLE, Esq., Childwall Lodge, Wavertree (gr. Mr. T. Hitchman). The varieties Ivanhoe, King Alfred and General Vette were extra good. R. G. MORRISON, Esq., Victoria Park, Wavertree (gr. Mr. H. Raper) was placed second. For six varieties of these plants Miss MCKEAN, Wavertree Lodge (gr. Mr. T. Rigg) was successful, whilst for six pots, three bulbs in each pot, Mr. E. R. FINCH was placed first. There were three good exhibits in the class for six pots of Daffodils. LOO THOMSON, Esq., Formby, led with a fine exhibit, his choicest varieties being Fairy, Glory of Leiden, and Mme. Plomp; 2nd, J. W. WRIGHT, Esq., Mossley Vale House, Mossley Vale (gr. Mr. T. Atkin). For twelve pots of single Tulips C. J. PROCTER, Esq., Boscobel, Oxton (gr. Mr. J. Williams) won with excellent specimens, and he won the 1st prize also in the class for six pots of single Tulips and six pots of double Tulips.

For eight vases of *Narcissi* Drs. TISDALL and INGAL, Tuebrook Villa, Tuebrook (gr. Mr. G. Osborne) excelled. The best basket of Daffodils was shown by Sir W. H. TATE, Highfield, Woolton. For six hybrid *Amaryllis*, A. A. PATON, Esq., Oneida, Toxteth Park (gr. Mr. W. R. Bentham) won with a fine lot, King Edward, a fine crimson, being noteworthy.

For two Orchids distinct, Mr. G. EATON led with grand plants of *Cymbidium Lowianum* and *Coelogyne cristata* Chatsworth var., G. L. PILKINGTON, Esq., The Grove, Gateacre (gr. Mr. H. Hurd). For two cool Orchids, J. B. HENSHAW, Esq., Aymerstry Court, Woolton (gr. Mr. H. Hudson) was first with good types of *Odontoglossum*.

Mr. G. EATON was well ahead with *Cinerarias*, winning in the three classes. Mr. J. MCCOLL had the best *Primulas*, Mr. F. ATKIN the *Lily-of-the-Valley*, E. H. COZENS-HARDY, Esq., The Hollies, Woolton, the *Cyclamen*; Mr. E. R. FINCH six table plants; three hardy *Azaleas*, Mr. H. OSBORNE; two *Callas*, Mr. G. EATON.

The show was greatly enhanced in value by the many and varied displays arranged "not for competition." Gold Medals were awarded to the following exhibitors:—Messrs. MANSELL AND HATCHER, Rawdon, for a capital display of Orchids. Messrs. SUTTON AND SONS arranged a charming display of Daffodils on velvet, which were greatly admired for the excellent taste shown. Messrs. BARR AND SONS' contribution of the same class, in which choiceness was the prevailing point, contained Michael and The General, and also a number of unnamed seedlings.

Mr. W. S. PEET, as secretary, discharged his new duties with success.

DEVON DAFFODIL AND SPRING FLOWER.

APRIL 2.—The spring show of the above Society was held in the Guildhall, Plymouth, on the 2nd inst. In many ways it was a great success, the flowering shrubs being quite as good as those exhibited two days earlier at Truro. The leading class for 24 varieties of Daffodils was keenly contested. The 1st prize was won by Miss CLARICE VIVIAN, whose flowers consisted of *Whitewell*, *Peregrine*, *Chaffinch*, *King Alfred*, *Epic*, *Scarlet Eye*, *Pilgrim*, *Firebrand*, *Ursula*, *Queen Sophia*, *Almira*, *Amazon*, *Cassandra*, *Diogenes*, *Cavalier* and others. For a group of Daffodil seedlings not yet in commerce the 1st prize was won by Mr. H. G. HAWKER. Six varieties *Trumpet*, 1st, Miss CLARICE VIVIAN, who also excelled in the classes for six varieties of bicolor *Trumpet* Daffodils; for six varieties of incomparabilis, with *Gloria Mundi*, *Homespun*, *Autocrat*, *Ursula*, *Queen Sophia* and *Léonie*; three varieties of *Barrii*, with *Castile*, *Coeur de Lion* and *Tomtit*; for three varieties of *Poeticus* with *Horace*, *Epic* and *Almira*; a single bloom of *incomparabilis*; and single bloom of *Poeticus* variety with *Tennyson*. For three varieties of *incomparabilis* the 1st prize was won by Mrs. SOLTAN-SYMONS with *Lady Margaret Boscawen*, *Lucifer* and *Pilgrim*. For three varieties of *Leedsii* the 1st prize was awarded to Earl of MORLEY with *Lord Kitchener*, *Queen of the North*, and *Janet Image*. For three varieties of double Daffodils Mr. H. G. HAWKER won the 1st prize, and he was also placed 1st for a single bloom of *Trumpet* Daffodil variety and a single bloom of *Leedsii* with *Evangeline*. Mrs. SOLTAN-SYMONS showed the best *Barrii* in Gold Coin. There were sixteen classes restricted to residents in Devon. In the class for twelve spring flowers the 1st prize was won by Mrs. SOLTAN-SYMONS. Other first prize-winners were Miss VONGE (six bunches *Anemones*), Earl of MORLEY (six bunches *Anemone fulgens* and three plants of *Polyanthus*), Hon. Mrs. TREMAYNE (three varieties of *Carnations*), and Mrs. HEATHCOTT (*Primroses*). For nine varieties of spring flowers the first prize was won by Mrs. FROUDE. The blooms of *Iris tingitana* received a Cultural Commendation. Mr. H. W. GRIGG showed best in the class for 15 varieties of flowering shrubs, and in this group *Osmanthus Delavayi* received a First-class Certificate. The competition in this class was so keen that there were only four points between the first three groups. Flowering shrubs in six varieties

were best shown by Mr. T. B. BOLITHO with *Grevillea Preissii* (Award of Merit), *Grevillea ornithopoda*, *Acacia diffusa*, *Eriostemon myoporoides*, *Dendromecon rigidum* and *Clematis indivisa lobata*. The Earl of MORLEY had the best group of *Rhododendrons*, and the finest truss of *Rhododendron*, and this nobleman also excelled in the classes for *Camellias*.

NON-COMPETITIVE EXHIBITS.

THE DEVON ROSERY, Torquay, showed flowering shrubs and Roses. Messrs. D. VEITCH AND SON, Exeter, showed *Camellia magnoliaeflora*, *Primula verticillata*, *Petrea volubile*, *Hibiscus magnificus*, and other shrubs. Messrs. BARR AND SONS, King Street, Covent Garden, contributed a very fine collection of Daffodils.

ROYAL METEOROLOGICAL.

MARCH 18.—The monthly meeting of this society was held on the 18th ult., at the Institution of Civil Engineers, Great George Street, Westminster, Mr. C. J. P. Cave, president, in the chair.

Professor A. C. SEWARD, F.R.S., gave a lecture on "Climate as Tested by Fossil Plants." Problems connected with the climates of past ages have long exercised the minds of scientific writers, both from an astronomical standpoint and from the point of view of the gradual development and wandering of plants and animals since the earliest periods that have left recognisable records. An estimate of the value of plants as "thermometers of the ages" necessitates an enquiry into the power of acclimatisation of recent plants and their ability to respond to external stimuli; a comparison of land and water plants illustrates the plasticity of vegetative organs and the intimate relation between form, structure and environment; similarly plants growing in dry places or in other conditions unfavourable for the absorption of water are characterised by certain structural features reflecting the circumstances in which they live. A comparison of individuals of the same species grown at high altitudes, at lower levels, or in continuous light affords striking evidence of the power of adaptation. The difficulty of using fossil plants as tests of climate becomes increasingly great in proportion to the degree of difference between the extinct types and their nearest living relations. It is from the examination of petrified plants, the delicate tissues of which are almost perfectly preserved, that data may be obtained throwing light on climatic conditions. This method of enquiry is best illustrated by a consideration of some of the anatomical features of the leaves, stems and roots of trees which grew in the forests of the coal period; the form and arrangement of cells in the leaves indicate fairly bright sunlight; large spaces in the cortex of roots point to growth in swamps. The geographical distribution of plants during the latter part of the Palaeozoic era affords evidence of the existence of two botanical provinces, a northern province characterised by a luxuriant flora living in conditions more genial than those to which the poorer flora of the southern hemisphere was exposed. The presence or absence of rings of growth in the petrified stems of plants may afford evidence of the occurrence or absence of seasonal changes. A general survey of the Jurassic flora of the world leads to the conclusion that the climate was comparatively uniform, and in Arctic and Antarctic regions much more genial than at the present day. The fossil floras of more recent geological periods furnish clear evidence of sub-tropical conditions in Europe; in later times the occurrence of northern types in Britain heralds the approach of the glacial period, and in post-glacial beds are found fragmentary remains of immigrants from neighbouring floras which have largely contributed to our present flora.

GARDENING APPOINTMENT.

Mr. F. Bailey, for the past 2½ years Foreman at Canwell Hall Gardens, Sutton Coldfield, as Gardener to A. Cross, Esq., Buxworth Hall, Northampton.

Obituary.

JOHN PATERSON.—By the death of Mr. John Paterson there has been severed one of the last links which bind the gardener of today with a former generation of noted Scottish gardeners. In the days when specimen Heaths and Azaleas were popular, Mr. Paterson was one of the most successful cultivators, and for his exhibits of these plants at the shows of the Royal Caledonian Horticultural Society he probably secured more awards than any other gardener of his time. Mr. Paterson's greatest feats in Heath and Azalea-growing were carried out at Millbank, Edinburgh, where for many years he was head gardener to the late Professor Syme. He afterwards removed to Saltoun Hall, East Lothian, as gardener to the late Mr. Fletcher, and after a number of years he retired from active service. He has since resided in the neighbouring village of Saltoun, where he passed away on the 27th ult.

FERN WITH DAMAGED LEAVES: *Beeleigh*. Your plant is *Asplenium Nidus* var. *australasicum*, and the fronds have been damaged by insects, probably wood-lice, which often eat the young leaves before they uncurl. Wood-lice may be trapped by placing pieces of vegetables, such as Carrot or Potato, in the greenhouse, examining them early in the morning and the last thing at night.

NAMES OF FRUITS: *G. C.* Apple *Roi d'Angleterre*.

NAMES OF PLANTS: *L. Y.* *Hedera hibernica* (Irish Ivy). The fine colouring of the foliage is due to local conditions.—*Bourville*. *Rose Marechal Niel*.—*C. G. A.*, *Leitchworth*. *Cardamine* sp. (cannot identify in this condition).—*H. E. S.* *Primula denticulata* var. *cashmiriana*.—*C. S. I.* *Cardamine triflora*; 2, *Saxifraga ligulata*; 3, *Veronica carnea*; 4, *Genista fragrans*; 5, *Buxus balearica*; 6, *Erica mediterranea*; 7, *Phillyrea media*; 8, *Anemone Hepatica*.

POISONOUS WEED IN FIELD: *A. J. C.* The reputation of Turnover (*Lamium purpureum*) in Huntingdonshire as poisonous to sheep and cattle, is probably due to some other plant growing in the same field, or not to any weed at all, if the symptoms described "rupture of blood-vessels" is the usual symptom in the fatal cases. A closely-allied species, *Lamium album*, is recommended in Herbs as a remedy in catarrhal conditions of the mucous membrane, and *Lamium purpureum* is classed with it by Gerarde and others. It has certainly never been recognised as a poisonous plant. The possible cause of the fatality may be due to the animals eating too much of the Lucerne. It is well known that in spring time, when animals are turned out to pasture on green food, after long deprivation during the winter, or only a sparing supply, that they are apt to eat of it excessively, and in these circumstances great abdominal distension and inflammation are apt to follow, the inflammation sometimes proving fatal. This is particularly the case with leguminous plants, which, to animals as to human beings, are "windy meat." It is possible that the mysterious instinct that animals possess may have led them to eat the *Lamium* as a remedy for inflammation, i.e., if it was found in their stomachs. No mention is made of *Lamium purpureum* as a poisonous plant in Dr. G. Lander's *Veterinary Toxicology* published recently.

Communications Received.—*G. B.* Blackwell (thanks for the Violets; very fine specimens).—*C. S.*—*G. L. V.*—*Capt. V. S.*—*R. A. D.*, Uganda—*R. Cory*—*W. M.*, Italy—*J. G. B.*—*F. R.*, Germany—*E. NITROLIM.

THE use of artificial manures enables the gardener to grow heavier crops than may be grown with the aid of animal manure alone. This has been known from time immemorial. In the Roman period, B.C. 55 to A.D. 410, the Britons used dung, wood ashes, lime, marl and chalk; then agriculture flourished—Britain was the granary of the Romans and "staff" of the Roman Empire. The Anglo-Saxons and Danes, 410 to 1066, relied chiefly on marls. In the Norman and Plantagenet periods, 1066 to 1399, agriculture used marls, chalk and dung, with recourse to bare fallows. The Houses of Lancaster and York, 1399 to 1485, reverted to pasture, wool being the most important item produced on the farm, and marls, chalk, and dung were the chief substances applied to restore the soil fertility. Under the House of Tudor, 1485 to 1603, the agriculturist and horticulturist woke up. They used, in addition to dung and lime, salt, fish refuse, street sweepings, malt dust and vegetable ashes, even

going so far as to employ coal dust and coal ashes, as well as sand. This period was marked by a great improvement in farming and gardening, a return being made to a rotation of crops. Clover was introduced and the cultivation of Potatos became a part of husbandry.

The House of Stuart, the Commonwealth and Restoration, 1603 to 1714, were chiefly notable, from the point of view of the cultivation of the land, for reliance on stable or farmyard manure as the way of returning to the soil the substances upon which all plant-growth depends. Attention was also paid in this period to draining of land and bringing into cultivation of the Fen districts. Naturally, this drainage of land tended in no small degree to the improvements in breeds of cattle, there being nothing like sound land for betterment of live-stock, as well as of crops. Under the rule of the House of Brunswick, 1714 to 1840, followed great improvements in cattle breeding, root-crops—turnip and mangel-wurzel—were introduced into husbandry, and farmyard manure was supplemented by bone manures, salt, etc. From 1840 bones, guanos, superphosphates, nitrates of potash and soda, sulphates and chlorides of potash and magnesia, with sulphate of ammonia, have been utilised as auxiliaries to stable and farmyard manure, and a scientific basis for the respective uses of these manures has been established. The precise uses of these manures, it must be admitted, were but little understood by farmers or gardeners in 1840, the garden routine consisting in the application of dung, any amount of it from the stables, soot from the mansion chimneys, wood ashes from the burned prunings of trees and clippings of hedges, etc., with a store of lime and a seasoning of salt, bones being reserved for vine borders and other fruit-producing subjects, while carbon in the way of charcoal was not overlooked. There was no science in these things but much practical knowledge, yet the gardeners then grew grand Pineapples and splendid Grapes, and the kitchen and dining-room never lacked supplies of prime comestibles. There were followers of Jethro Tull in those days—spadesmen devoted to deep-digging, there being virtue in mixing soil equal to that in good manuring, a fact well known to the ancient Romans and not yet lost to Britons, as witness the precepts of such moderns as Mr. Edwin Beckett, the champion of deep cultivation and grower of prize-winning vegetables.

The old gardeners relished, as did their plants and crops, a little stimulus, such as a pinch of Peruvian guano or its solution in water as liquid manure, and they got from this to the use of nitrogenous, phosphatic and potassic substances, so as to enable them or their successors before the close of the nineteenth century to grow crops two or three times as heavy as were possible without the aid of artificial fertilisers. This is a very important matter in many gardens at the present time when the motor-car is supplanting the carriage, petrol the horse-power, for the former returns nothing to the soil while the latter yields the indispensable humus for the maintenance of the soil in "condition" and for the deriving of full benefit from applied artificial fertilisers.

Of artificial fertilisers it may be said that three substances contained in them only may be valued and charged for, namely, nitrogen, phosphates and potash, and that a soil lacking any one of these in an available form cannot produce a maximum crop. All three are necessary in well-balanced proportions, the quantities of each depending upon the particular requirements of the crop and the available quantities present in the soil. Nitrogen is the main essential of all plant growth, a powerful stimulant without which plants cannot develop (excepting such as derive nitrogen from the atmosphere), while in excess it produces rank growth at the sacrifice of quality. Phosphates are required to promote the

healthy growth of the plants and hasten the maturity of their crops. Potash, in combination with nitrogen and phosphates, is the prime factor as regards health—the first wealth, and is found in large proportions in all plant tissues, lack of fruitfulness and of quality resulting from its absence. All artificial fertilisers contain other ingredients, some useful, others harmful; therefore it is necessary to have a detailed analysis of a special article in order that the gardener may know the substances, and the amounts of those substances which it contains.

Nitrolim, one of the newer sources of nitrogen, contains also lime and carbon, as given in the following approximate analysis:—

Nitrogen, 18 per cent., expressed as ammonia ..	21.85	per cent.
Free lime ..	20.30	" "
Lime in combination ..	20.30	" "
Carbon ..	10-12	" "
Oxides of iron and alumina ..	2.5	" "
Siliceous and other inert mineral substances ..	8-10	" "

The active principle is the nitrogen, but this, being in the form of ammonia, requires time for conversion into nitrate, which depends in a great measure on the presence or application of lime. This is an important constituent of nitrolim. Upon it depends the activity of the nitrifying bacteria, beside which it also is an indispensable plant food, while it tends to sweeten acid soils. Lime also prevents the caking of clay lands, reacting on the soil particles, and brings potash into soluble form, and thus renders it available for plants.

On sandy soils the best results from the application of potash are secured only in the presence of sufficient lime, for without this substance a considerable proportion of potash—the essence of fertility on sandy soils—is liable to be lost. On the other hand, heavy soils, and even the lighter soils, well provided with lime, hold on tenaciously to the potash which they receive, and crops in consequence are healthy and profitable.

Soils poor in lime and to which superphosphate is applied as a fertiliser suffer by the reaction of the acid on other soil constituents. If, however, plenty of lime is present the insoluble compounds cannot form and the phosphate is retained as superphosphate of lime, which is readily available as plant food.

Carbon may be said to be soil-sweetening, and the old-fashioned gardener's practice of using charcoal in potting soil and in vine and other fruit borders, where the vines or trees had to remain long in the same soil, seems a method of soil-sweetening, conjointly with the lime, of considerable importance. The carbon in nitrolim is as pure as the electric furnace can make it, and its extreme fineness renders it readily diffusible through the soil.

The active fertilising constituent of nitrolim, however, is nitrogen, guaranteed 18 per cent., and this in a suitable condition for ready assimilation. In appearance nitrolim is a dark, fine, heavy powder. As regards solubility, quickness of action, and other properties, it closely resembles sulphate of ammonia, and is suitable for most purposes for which sulphate of ammonia is employed. It has a lasting effect and does not wash out of the soil like nitrate of soda, therefore its benefits are not exhausted in the year of application, but continue for some time afterwards provided the soil also contains a sufficient supply of available phosphate and potash. This is likewise a necessity of nitrolim application—either the land must have an ample supply of phosphate and potash from a previous crop or these substances must be provided by admixture with the nitrolim or applied separately. A good general mixture may be

made as follows:—Nitrolim, $1\frac{1}{2}$ parts; superphosphate of lime, 6 parts; sulphate of potash, $1\frac{1}{2}$ parts. The potassic manure should be mixed with the nitrolim first; superphosphate should then be added to the nitrolim and potash mixture in thin layers at a time. Should the heap get hot during the mixing water must be sprinkled over it, care being taken, however, not to add too much or the heap will become pasty. This mixture is a good all-round fertiliser and may be applied at the rate of 9 cwt. per acre, $6\frac{1}{4}$ lb. per square rod, $5\frac{1}{4}$ oz. (or a little more) per square yard. The mixture should be applied in preparing ground for sowing seed or setting plants or "sets"—say ten days or a fortnight before sowing or planting, mixing well with the soil. If used as a top-dressing for fruit trees, etc., the manure should be mixed with six times its weight of finely divided damp earth and allowed to stand for a few days before

Nitrolim has other properties, those of a weed killer and a soil-pest destroyer being of importance. The quantities of nitrolim before mentioned for separate application, if applied on the first appearance of weeds, destroys most of them, but the dusting naturally affects the growing crop, the leaves assuming a light-yellow colour; but this effect is temporary and disappears, and the consequent remarkable improvement becomes the more apparent through the favourable effect of the nitrogen and lime. Albeit, the use of nitrolim as a top-dressing may not always be considered advisable, for crops that hold it as well as weeds are just as likely to be injured, if not destroyed.

As regards the destruction of weeds and of soil-pests, I may mention that a plot of land badly infested with slugs and with weed seeds was given a dressing of nitrolim in the spring of 1912. lightly pointed in and left for a fortnight,

FIG. 114.—ACACIA DECURRENS VAR. DEALBATA.

application. This applies to all cases of top-dressing.

For separate application nitrolim is a somewhat difficult substance to handle, as I found when first applying it, the free lime acting on the moisture of the hands and other exposed parts of the body, and producing irritating and burning action. This may be overcome by wearing cotton gloves bound around the shirt sleeves and wrists with a cloth bandage, wearing a handkerchief around the neck and tying the trouser-legs around the ankles. The hands, however, are the only parts that need protection in using nitrolim in the garden. The quantity of nitrolim to use separately is $1\frac{1}{2}$ cwt. to 2 cwt. per acre, 1 lb. to $1\frac{1}{4}$ lb. per square rod, $\frac{1}{2}$ oz. to $\frac{3}{4}$ oz. per square yard. It must not be applied directly over foliage or placed in direct contact with stems, since it seriously injures the former and even destroys the latter, killing the plants. It should be lightly hoed in, and may be used advantageously to crops needing nitrogen.

and then well forked over in preparation for setting summer bedding plants. It proved not only free from slugs in that season, and also remarkably free from weeds, but there were very few slugs in 1913, as also fewer weeds.

Nitrolim is nitrogen obtained from the air by a process of distillation at an excessively low temperature. The nitrogen is combined with calcium carbide by an electric process at a temperature approximating $1,000^{\circ}$ C. thus forming calcium cyanide, which is subsequently ground to a fine powder, partly hydrated, so as to produce the finished product free from carbide and dustless.

I believe superphosphate mixed with nitrolim in course of manufacture can be obtained from the principal manure manufacturers and merchants in Great Britain and Ireland. This compound presents the advantage of forming a mixture (by the addition of potash or otherwise) easy to handle on the farm and in the garden. *G. Abbey, St. Albans.*

NEW OR NOTEWORTHY PLANTS.

HYBRID ACACIA H. L. WHITE.

In the *Gardeners' Chronicle*, October 4, 1913, p. 236, a note appeared from Mr. J. H. Maiden, Director of the Botanic Gardens, Sydney, on a hybrid Acacia which he had named in compliment to Mr. H. L. White, of Belltrees, Scone, in whose garden it flowered the previous year. The parents were not definitely stated. It was, however, assumed that *Acacia dealbata* (see fig. 114) was the seed parent, and *A. Baileyana* (see fig. 115) the male parent, as both these species were growing in close proximity to each other. Having examined a dried specimen of the hybrid, I have no doubt but that Mr. Maiden's assumption as to the parentage is correct. Although it possesses characters intermediate between those of its parents, the dried floriferous spray of the hybrid suggests a more marked resemblance to *A. dealbata* in the long, loose racemes of globular flowers, which in *A. Baileyana* are comparatively short. The leaves also favour the seed-parent by being disposed at greater intervals along the branches, and while the leaflets are quite intermediate in length they do not possess that bluish tint which is characteristic of *A. Baileyana*. It would be interesting to learn whether the hybrid is likely to inherit the strong, vigorous growth of *A. dealbata*, and also whether the flowers possess the delicious fragrance of that species.

Among the large number of Australian Wattles the parents of this hybrid are, perhaps, more extensively cultivated in European gardens than any other Acacias. In the warmer parts of the British Isles there are many gardens in which they thrive and flower freely in the open air, but where the climatic conditions are not so favourable they require the protection of a greenhouse.

Acacia dealbata, "The Silver Wattle" (see fig. 114), is a well-known species of very vigorous habit, therefore it cannot be recommended for pot culture; but when planted in the border of a large house it seldom fails to produce a glorious display of its fluffy, yellow balls of flowers soon after Christmas. During the first three months of the year large quantities come into the English markets, chiefly from the South of France, when it is sold in our streets under the erroneous name of "Mimosa."

Acacia Baileyana, "The Cootamundra Wattle" (see fig. 115) is a very beautiful species, which has come into prominence during recent years. It forms a small tree about 20 feet high and comes into bloom at least a fortnight earlier than *A. dealbata*. The deep yellow flowers are produced in great profusion; they harmonise splendidly with the small pinnate leaves, which possess a decidedly bluish colour. In the vicinity of large towns it is occasionally injured by fogs, which cause the leaves and flower-buds to drop to some extent. This lovely Acacia promises to become a general favourite in English gardens as it has proved to be the hardiest of the genus.

Acacia H. L. White (see fig. 116) appears to be very floriferous, therefore it should prove a valuable addition to gardens where Acacias thrive out-of-doors; more especially does this apply if it is intermediate in habit of growth, and possesses the hardiness of *Acacia Baileyana*. *H. T.*

ORCHID NOTES AND CLEANINGS.

MESSRS. ARMSTRONG AND BROWN.

WE had the opportunity on a recent occasion of inspecting the excellent block of houses at this interesting nursery at Tunbridge Wells (see illustration in *Gardeners'*

Chronicle, December 16, 1911, p. 430). In the first large house, where throughout the late winter some hundreds of the handsome *Cattleya* Maggie Raphael Orchidhurst variety displayed their large, fragrant blooms, were many fine Laelio-Cattleyas in flower, one of the best being L.-C. Geo. Woodhams, raised by Mr. Armstrong, a showy, finely-coloured flower and excellent grower. With it was L.-C. Macqueda (Laelia Geo. Woodhams × *Cattleya* Lord Rothschild), a stately hybrid. Other hybrids in their first flowers prove the high quality of the parents used. Some hybrids of *Cattleya* Schrödera with yellow-tinted Laelio-Cattleyas exhibited great variety in shades of yellow, from primrose to orange, with variously tinted labellums, all on flowers of good shape. A very handsome form of *Cattleya* Niobe (Mendelii × Aclandiae) was remarked. Mendelii, being the seed-bearer, gives a much stronger growth and larger flower than the original, the white and rose-purple blooms being nearly as large as *C. Mendelii* itself and of very fine substance. Some plants of Laelio-Cattleya Myra and hybrids of it have the yellow petals of Myra on larger flowers, with ruby-coloured lip; and some excellent forms of *Cattleya* Schrödera, the white *C. Susannae* Hye de Crom, and other large-flowered Cattleyas, were in bloom, while for later-flowering the numerous flower-sheaths give assurance of a fine display.

Several houses of unflowered hybrid Cattleyas, Laelias and Brassavola Digbyana crosses, were in fine condition, the healthy roots of the plants in all stages being a good feature. This free-root action is attributed to the uniformly moist atmosphere maintained by evaporation from the arched brickwork on which the stages are arranged, which evaporation is always proportionate to the temperature of the house. Watering by means of the waterpot is carefully restricted, as it is found that Cattleyas and Laelias root more freely and make better growths when not heavily watered, the roots being induced to develop by the moisture in the air.

The houses of *Cypripedium*s contained a large number of good things in bloom. Varieties of *C. Leeanum*, *C. aureum*, the beautiful *C. Moonbeam*, *C. Bianca*, *C. Beryl*, *C. Beeckmannii*, and some hybrids of it; the handsome *C. Venus* Orchidhurst variety, *C. Maudiae*, *C. Holdenii*, *C. Lawrenceanum* in fine coloured forms, and the still rare emerald-green and white *C. Lawrenceanum* Hyeanum; forms of *C. Euryades*, an interesting lot of *C. Fairrieanum* crosses, *C. Queen Alexandra*, and a very large number of hybrids. As time passes the standard of excellence rises, and although most of the hybrids are acceptable for decorative purposes, it is found that only really fine and distinct things command high prices, and for these, as Mr. Armstrong says, the raiser has a strong liking himself. A case in point is the noble *Cypripedium* Royal George (*Harrisianum* superbum × *Minos Youngii*), which Messrs. Armstrong and Brown sold, but of which they have again acquired the stock.

In the cool houses was a good show of scarlet *Odontiodas* and hybrid *Odontoglossums*, some of which were flowering on small plants for the first time. To the casual observer several different crosses with blotched *O. crispum* appeared at first sight to be identical with each other, but the expert could easily detect differences inherited from the species which produced them. As the plants gain strength these characters appear more strongly marked, though in all the *O. crispum* section good shape is retained. It is also noticeable that the progeny of two blotched forms of *O. crispum* often show variation in the form of the labellum almost identical with that of some of the hybrids. This throws doubt on the claim of the blotched *O. crispum* as a species.

Forms of *O. eximium*, *O. ardentissimum*, *O.*

percultum, *O. amabile*, and others were in bloom, one fine hybrid between *O. amabile* and *O. eximium* being specially attractive.

Before the coming of the *Odontioda* there was a dearth of scarlet and other red flowers, especially in winter and spring, but with a good supply of *Odontiodas* bright colour is present for a great part of the year. Those in bloom at Orchidhurst have given a good show for a considerable time, the brightest at present being *O. Charlesworthii*, *O. Keighleyensis*, *O. Bradshawiae*, *O. Vuylstekeae* and *O. rosefieldiensis*. These give a brilliant display, and the modest cinnamon-scarlet *Cochlioda* Neezliana, without which they would have been impossible, although pretty, looks comparatively insignificant in the presence of its offspring.

With these some good typical *Odontoglossum* *crispum* were in bloom, one plant carrying a four-branched spike of thirty-three flowers; and

NOTES ON IRISES.

IRIS ROSENBACHIANA.

This gorgeous Iris is unique in more ways than one. To the botanist it is interesting because its seeds are entirely unlike those of any other Iris in cultivation, while the gardener's curiosity and astonishment are aroused by the great development of the fleshy roots, which are usually four or five in number, and often as large as the bulb itself. In the upper parts they are very thick, then suddenly decrease in diameter, and end in a long, thin thong. No other Juno Iris is known to possess roots so large in proportion to the size of the bulb.

Gorgeous seems to be the word that we must apply to this Iris when we see a sun-lit group of the brightly-coloured flowers standing out

FIG. 115.—ACACIA BAILEYANA.

Flowering shoot, 1/2 nat. size; details magnified. (See p. 262.)

some *O. Pescatorei* of an excellent type, one having very large flowers of fine form, heavily tinged with purple at the back, the colour showing through to the surface, and a distinct red-blotched lip. A batch of *Miltonias* had some good *M. vexillaria*, *M. Bleuana*, *M. Hyeana* and *M. St. Andre* in bloom. At the end of a warm, moist house large specimens of *Coelogyne pandurata* were in extraordinary vigour, and in an intermediate house a batch of albino Cattleyas was noted.

The corridor, which connects the houses and offices, contained a very fine display of *Dendrobiums*. These had been in bloom for a long time, and among them some hundreds of the pure-white *Dendrobium nobile virginale* have flowered. In hybridising the production of yellows is being attempted with good results. In the North House in bloom were some showy *Cymbidium* varieties of *C. insigne* and its hybrids, *C. Woodhamsianum*, *C. Wiganianum* and *C. eburneum*. Also varieties of *Lycaste* *Skinneri* and *Masdevallias*.

against the sombre background of the bare earth, for the leaves are so immature at flowering-time as hardly to attract the eye at all.

Early in the new year broad, nipple-like shoots with a whitish, membranous sheath begin to burst through the surface of the ground. Soon the tips of the leaves appear through the sheath, and then suddenly, often almost in one night, the flowers shoot up and open, if the sun appears only for a few minutes.

There are, I am convinced, local forms of this Iris, the peculiarities of which are preserved by at least the first generation of seedlings. There is an early flowering race with yellow pollen, and so far as I know, few colour variations, and a later race of which the pollen is white, and of which hardly any two plants produce flowers of the same shade of colour. For the last month I have had in flower between 20 and 30 seedling plants of the earlier kind. Each flower lasts a week or more, and as each bulb throws up two or three flowers in succession a group of these Irises is a lasting pleasure. It was

certainly disappointing to find so little variation in colour among these seedlings, for, although it is true that minute differences were numerous—for instance, the "standards" were either horizontal or drooping, some pointed, others broad and obtuse—the general effect was uniform.

The strap-shaped falls have along the haft, flanking a yellow or orange central ridge, either four or six crimson-purple veins on a silvery-white ground, which is often slightly suffused with a pale red-purple. On the blade the central ridge becomes a crest and is sometimes irregularly dotted with crimson-purple. It is surrounded by a large patch of the same brilliant colour, which covers all the blade of the falls with the exception of the tip, which is a pure white. The large overlapping crests of the style-

My experience is that *I. Rosenbachiana* makes very few offsets. A flowering bulb is only obtained from seed after four or five years of growth. It then flowers regularly for three, four, or even five years, after which it either dwindles away or dies outright. Fortunately, however, this *Iris* seems to be peculiarly well adapted for easy fertilisation. The stigmatic surface is larger and more prominent than in most, if not in all, other *Iris*es. The anthers also are large, and the pollen very abundant. Seed sets readily if the flowers are cross-fertilised one with another, and provided that the plants are given some shelter from heavy rain. I have counted so many as 80 or 90 seeds in a single capsule, and their very number may be an indication that it is a plant which must be continu-

PLANT NOTES.

CAMPANULA PYRAMIDALIS.

UNDER good cultivation splendid specimens of the Chimney Campanula may be grown from seed in fifteen or eighteen months. The cultivator should aim at securing good plants with strong crowns by the autumn of the first year, and to attain this the seed should be sown in spring in well-drained pans, using a light, friable soil sifted through a fine sieve. As the seed is very fine, the pans should be immersed in tepid water before sowing. Sprinkle the seeds evenly over the surface, cover them lightly with fine soil or sand, and press them down. Cover the seed-pans with a piece of glass, placing over this a layer of paper, and germinate the seeds on a mild hotbed. As soon as the seedlings appear remove the coverings, and put the pan near to the roof-glass in a frame that can be well ventilated, thus ensuring sturdy growth from the beginning. When large enough to handle, prick them off singly into small pots, using a compost of two parts fibrous loam, one part leaf-mould, and one part manure from an old hotbed, with a good dash of sand and mortar rubble. Place the plants again in the frame, shade them from bright sunshine for a few days afterwards, and syringe to encourage a free growth. If the roots are watered carefully they will soon fill the pots, when the plants may be re-potted, this time into large sixties, using slightly rougher soil. At this stage cold frame treatment is suitable, closing the lights every afternoon and spraying them at the same time for a week or two to give the plants a good start. As the pots become filled with roots water the latter with diluted liquid manure or feed them with a concentrated fertiliser. The plants produce roots very quickly, therefore no time should be lost in potting them on into six-inch pots when once they are ready, for they must not receive a check from becoming pot-bound. Soil similar to that used in the earlier stages will suit them, but the loam should be pulled to pieces about the size of walnuts. Sift the leaf-mould and manure through a half-inch sieve, and in addition to the sand and mortar rubble add a six-inch pot of coarse bone-meal to every barrow-load of the compost. Pot firmly, and place the plants back in the frame for a few days, after which, if the frames are required for other purposes, the Campanulas will do well outdoors on a bed of coal ashes. Attend to watering and feeding the roots as before advised, until the winter, when but little water will be required. The pots may be plunged in a bed of leaves or cocoa-nut fibre refuse beneath a covering of old frame lights, which will ward off rains or snow. Protection is only necessary in very cold weather, when litter or bracken may be thrown over them. Under this treatment they will do very well until February, when they may be potted into eight or nine inch pots. I prefer to pot them singly, as the plants differ very much in their growth, some throwing up only one strong spike, whilst others develop seven, eight, or even more. Rich soil in a rough condition should be used at this potting. The addition of fertiliser or soot will enhance the colour of the flowers and foliage. The soil is best mixed several days before use, storing it in a dry shed. Use clean, well-drained pots. After potting transfer the plants to a cold frame, and afford water with extra care. With the advent of warmer weather the flower spikes will soon develop, and the plants may then be removed to the greenhouse. Feed the roots freely until the flowers begin to show colour, and then use clear water only. Secure each plant to a neat stake. Remove the blossoms as they fade, and give the plants a little stimulant, for this will result in a second crop of flowers, although they will not be quite so large individually as those of the first spike. In hot, bright weather shade the

FIG. 116.—HYBRID ACACIA H. L. WHITE (*A. DECURRENS DEALBATA* × *A. BAILEYANA*).
Flowering spray, $\frac{1}{2}$ nat. size; leaf mult. 2. (See p. 262.)

branches are either white or white faintly flushed with red-purple, and the standards are of the same colour. The style-branches have a central band of pale red-purple changing to yellowish at the base on a silvery-white ground. The flower measures 3 or 4 inches across and is raised on a long perianth-tube of a yellowish-purple colour, rising 1 to 3 inches above the top of the spathes. In the only other colour form of this early variety that is known to me the silvery-white ground is replaced throughout by a pale red-purple.

On the other hand, the later race is extraordinarily variable. The plants begin to come into flower just when the last flowers of the earlier race are fading. All shades of both blue and red-purple occur, and yellow flowers, though rare, are not entirely unknown. The blooms are perhaps rather smaller than those of the earlier race, and the plant seems to be less vigorous.

ally raised from seeds. The latter should be sown at once in pots plunged in the open, and may be sown very thickly, for only a few germinate each year. Each summer the minute bulbs and the remainder of the seeds must be sifted out, and the latter re-sown at once. The young bulbs do best planted out under the protection of a cold frame.

Owing to the nature of the rootstock this *Iris* must be extremely difficult to collect satisfactorily in the wild state from the hard sunbaked soil of the steppes and mountain slopes of Turkistan. Consequently we must usually rely on home-raised seedlings to replenish our stock. If, therefore, anyone who sees these notes has specimens of this *Iris*, I would suggest an exchange of seeds or bulbs in order that, by cross-fertilisation, we may be able to keep it in cultivation. *W. R. Dykes, Charterhouse, Godalming.*

plants when in bloom, or the flowers will fade quickly. Any plants not required for pot culture may be planted out in the borders, where they will throw up fine spikes of flowers; but as there are so many other hardy varieties of Campanulas, *C. pyramidalis* may be used mainly for indoor decoration. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

NOTICES OF BOOKS.

A CONTRIBUTION TO THE HISTORY OF BOTANY AND GARDENING.*

PROFESSOR VINES and Mr. Druce have followed up their *Account of the Dillenian Collections in the Herbarium of the University of Oxford* with a further and worthy contribution to the history of the botanical pioneers and botanical possessions of the venerable institution which they represent. It is interesting alike to botanists and horticulturists that these early collections of dried plants should be classified, named, arranged in an accessible manner, and their elements put on permanent record. That the editors' task has been critically performed may be taken for granted from the long list of specialist coadjutors on page lxxviii. The introduction of upwards of sixty pages is the most generally interesting section of the book, beginning with the foundation of the garden and the Professorship of Botany at Oxford, and continuing with the history of the garden, personages and events of the botanical establishment of the period, down to 1720. It is embellished by a view of the Danby Gateway, erected in 1632, and portraits of Earl Danby, Morison and the Bobarts, father and son. Some of the leading facts are here given in extract. The Physic Garden was founded by the Earl of Danby in 1621, and, although the oldest of its kind in Britain, it is not nearly the oldest in Europe, having been preceded by those of Padua (1545), Pisa (1547), Bologna (1567), Leiden (1577), and Montpellier (1598). It is a singular fact, the authors state, that the true date of the foundation of the Oxford Garden has not been given previously in any of the very numerous books which refer, directly or indirectly, to its history. Though the formation of the garden was begun in 1621, it was some years after 1632 that Jacob Bobart, sen., was appointed the first Superintendent; but the exact date has not been ascertained. It seems, however, that there had been previous negotiations with John Tradescant, sen., sometime gardener to Charles I. Bobart was a German by birth, and was twice married, whether to English women or not is not actually stated, but their Christian names are in the English form. From the published accounts of distinguished visitors to the gardens we learn that Bobart was an accomplished gardener. A feature of the garden in later years was offered by some remarkable examples of topiary work by the elder Bobart. Two, especially, are noticed, clipped to represent men, the one bearing a club, the other a halberd, which finally grew up to be gigantic, bulky fellows. A catalogue of plants cultivated in the garden appeared in 1648. It contains names of no less than 1,600 species, of which 600 were British, and many were Canadian.

Robert Morison, a native of Aberdeen, born in 1620, was chosen first Professor of Botany at Oxford in 1669, after a successful educational career at home and abroad. He was a prolific writer, and, in a way, one of the pioneers in the classification of plants, though his contemporary, Ray, excelled in this direction.

* *An Account of the Morisonian Herbarium in the Possession of the University of Oxford, together with Biographical and Critical Sketches of Morison and the Two Bobarts and Their Works and the Early History of the Physic Garden, 1619-1720.* By S. H. Vines and G. Claridge Druce. (Oxford: Clarendon Press, 1914.) Small 8vo, pp. lxxviii. + 350. Price 15s. net.

Jacob Bobart, the younger, succeeded his father as Superintendent of the Garden, and, later, Morison as Professor of Botany. He also edited the third part of Morison's great work: *Plantarum Historiae Universalis Oxoniensis*.

The Morisonian Herbarium was prepared to illustrate the *Historia Universalis, etc.*, and consists of about 6,500 specimens, derived from all parts of the world, and the present book is a record of its contents under pre-Linnean designations or phrases, together with the generally accepted modern names. *W. Botting Hemsley.*

his little volume a supplement, including the English and Continental publications up to date, and an index of authors which will considerably increase the usefulness of the work. The book is printed on good, stout paper.

FLORA OF KATANGA.

THE botanical collections made by numerous travellers in the Belgian Congo have been worked out with great assiduity by the late Th. Durand and by Em. de Wildeman, his successor as director of the Brussels Botanic Garden, and the results published in a some-

THE FLORISTS' BIBLIOGRAPHY.*

It is now more than five years since the first edition of the *Florists' Bibliography* was published. It was then fully up to date; but the last half-decade has been a busy one among garden authors, and a very large number of new books have appeared on horticultural subjects, some insignificant, but many of real importance. The author, recognising this fact, has added to

what bulky form in the *Annales du Musée du Congo Belge*. The Botany has appeared in five series of one or more volumes each, and includes several hundred plates. The contents of most of these volumes have been described in these columns. The last to hand is the first fascicle of the second volume of *Etudes sur la Flore du Katanga*. The Katanga district borders on Rhodesia, therefore this publication is of importance and interest on the British side. This part is illustrated by about a score of plates giving full-sized representations of herbarium types.

* *The 'Florists' Bibliography.* By C. Harman Payne. Second edition, with Supplement and Index. W. Wesley and Son, London. Price 5s., cloth gilt.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

COELOGYNE DAYANA.—This plant is producing flower scapes from the centres of the developing growths, and the roots require a liberal supply of moisture. Afford the plants every encouragement to assist them to develop their flowers. It is my experience that the plants grow best when suspended from the roof at the cooler end of the plant stove, and for this reason they should be planted in shallow pans or baskets. Grown in this way the pendent racemes of flowers are seen to the best advantage. The plants should be kept in the same position after the flowers commence to expand, as the least disturbance causes the flower scape to become twisted, often destroying the effective arrangement of the flowers. Potting is best done immediately after the flowers are over. It is not desirable to repot annually; for this reason the compost should be of a lasting nature, and may consist of a mixture of AI fibre, peat and Sphagnum-moss in equal proportions. Make the soil moderately firm about the roots.

PHAIUS.—Plants of Phaius that have passed out of flower, and hybrids of *P. simulans* that have failed to bloom, may be repotted. *P. Cooksonii* and the numerous varieties of *P. Norman* grow most satisfactorily where the conditions are suitable, and they are exceedingly useful plants for all purposes of house decorations from the middle of March until the month of May. In this district many fine plants of this Orchid are grown in ordinary plant stoves where there is plenty of humidity in the atmosphere at all times. A compost consisting of equal portions of fibrous peat, turfy loam and leaf-mould with plenty of sand intermixed is suitable to their requirements. The roots are fleshy, and need plenty of room. The pots should be clean and filled to about one-third their depth with clean broken crock for drainage. The compost should be made firm, and if a layer of chopped Sphagnum is placed over the surface it will give a smart appearance. Afford water sparingly at first, but as soon as the roots become established liberal supplies of moisture may be afforded. Spraying at regular intervals of about once a fortnight during the summer will keep thrips in check. Scale insects are also troublesome to these plants, and the leaves should be sponged carefully as soon as these pests are detected, or they will soon cause a permanent disfigurement of the foliage. Frequent dampings of the bare spaces to keep the atmosphere humid will be beneficial in keeping insect pests in check. The members of this class of Phaius do not benefit by direct sunshine during the spring, summer, and early autumn, therefore the blinds should be drawn down early in the morning if the plants are placed where they will receive the sunshine. Later in the season a light permanent shading may be placed on the roof.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOTE,
Eastwell Park, Kent.

APRICOTS are the earliest fruit trees to expand their blossoms, and the first to require disbudding. Though the removal of superfluous growths should be commenced as soon as the shoots are large enough to handle, in severe weather it is better to postpone the work until the conditions are more favourable. The disbudding of Apricots is not done so severely as in the case of Peaches and Nectarines; the principal object is to remove badly-placed shoots, such as those that grow behind the branches and close to the wall, and any that develop at right angles to the face of the tree. In the case of trees that have filled their allotted spaces the pinching of superfluous shoots to three or four

leaves will tend to make them form fruit spurs. Do not disbud too many of the branches at one time, but go carefully over the upper part of the tree first; then, after a few days do the centre part, and after another interval complete the work by doing the bottom of the tree. Where protection has been afforded let the material remain in position at night till all danger from frost is past, as severe frosts are often experienced late in April.

GOOSEBERRIES.—There is every prospect for a good crop of these fruits. Gooseberry bushes often receive very little attention beyond the annual pruning. Too often, in common with other small fruits, the plants are cropped heavily year after year, and little or no manure is afforded the roots, with the result that the bushes deteriorate, and, lacking vitality, fall an easy prey to insect and fungous pests, whilst the fruit is of inferior size and quality. If a supply of animal manures was not available for top-dressing the bushes in winter, a dressing of fish manure or other fertiliser should be spread on the ground now. Wood ash, lime and soot may with advantage be mixed with the manure and the materials forked lightly in the soil, or, if the latter is of a light open texture, hoeing the surface will suffice. This treatment will greatly benefit the bushes, enabling them to develop their berries early. Gooseberries are much appreciated as dessert fruits, and to obtain extra fine berries the crop should be thinned early—as soon as the berries are as large as Peas. Those that remain should be allowed to grow until they are nearly full size, when the bulk should be picked, leaving a few of the best to ripen. Green Gooseberries are much appreciated for the making of preserves.

GENERAL REMARKS.—Soil of a heavy retentive nature has become caked on the surface by heavy rains since it was dug in winter, and the crust should be broken with the fork. This will greatly facilitate the work of hoeing during the summer, and will tend to keep the surface open and friable. Nothing assists fruit trees in making free, healthy growth so much as constantly moving the surface soil, either by hoeing or forking, according to the nature of the ground; moreover, weeds have no opportunity of becoming established when this work is carried out in a systematic manner. Fruit trees that have borne heavy crops of fruit and have not been fed with farmyard manure for some considerable time should be afforded artificial stimulant in the form of fish manure, bone meal, or other quickly-assimilated manure. The fertiliser should be sprinkled on the surface before hoeing or forking the soil, and will soon be washed down to the roots, benefiting the trees in time to assist them to develop their crops.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

ANNUALS.—Seedling annuals growing in boxes, pans or pots need careful attention, as they may become drawn if neglected, and spindly plants never give satisfactory results. Thin or transplant the seedlings directly they are large enough for removal. Those of the stronger-growing kinds may be pricked out in beds of soil arranged on the floor of cold frames. It is an advantage to first spread some finely-broken manure on the bottom of the frame, for the roots will grow into this, rendering it an easy matter to lift the plants with good balls of soil.

BULBS IN THE GRASS.—At Madresfield we have a good variety of bulbous flowers already expanded. The Dog's Tooth Violet, *Erythronium Denscanis*, has succeeded with us in the grass for the first time this season. It is a case of patience rewarded, for the clumps are strong both in flower and foliage. *Fritillaria Meleagris*, the Snake's Head; *Narcissus poeticus ornatus*, Muscari (Grape Hyacinth), *Anemone apennina* and *A. fulgens* are all exceptionally fine. *A. apennina* appears as a sheet of azure blue in the bright sunshine. All these plants require some years to become thoroughly established, and they thrive best near deciduous trees, for in such positions the grass does not grow so rank as to smother the plants after they have flowered.

WILD FLOWERS.—In these gardens certain wild flowers are encouraged to grow in large patches, and they give a delightful effect. Few flowers have a more delicious perfume or are more greatly appreciated than the white wood Violet, and none appears more beautiful than Primroses, Cowslips, Bluebells, Buttercups, Anemones, Agrimony, Loosestrife, and wild Orchids, arranged in dells. All are easily grown, and they may be afforded space in the wild garden or along woodland paths.

CLIMBERS.—Plants of summer-flowering Clematis, whether trained on arches, pergolas, or walls, need constant attention in the matters of training and spreading out the young growths, which develop rapidly at this season, and soon become intertwined if neglected. Our plants of *Jasminum primulinum*, trained loosely on south or west walls, are very handsome just now, bearing a profusion of their large yellow flowers, and they look well associated with the dark blue-flowered *Ceanothus rigidus*. *Clematis montana rubens* should be grown in every collection. Allow the plants plenty of room for extension; they look fine rambling over old trees that have been lopped 10 or 20 feet from the ground. *C. flammula* flowers in the late summer or autumn, when the blossoms perfume the whole vicinity. *Wistaria sinensis* and the early and late-flowering Dutch Honeysuckles are other beautiful climbing plants, whilst climbing Roses are universal favourites.

WATER-LILIES.—Nymphaeas may be propagated by division of the root-stocks just as growth commences. Division of the old plants is necessary periodically, in order to obtain large flowers; for, as in other plants, overcrowding of the shoots results in inferior flowers. Divided plants soon make fine specimens that flower well. The late Mr. W. Coleman, of Eastnor, grew Water-Lilies very successfully in old paraffin casks, cut through the middle, and sunk on the lawn to the ground level.

FRUITS UNDER GLASS.

By W. HEOLY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

STRAWBERRIES.—Examine the plants in pots at least twice a day during bright weather, and water copiously such as are dry. The airing of the house must be done carefully when drying winds prevail, for cold currents of air cause the young fruits to partially dry up and cease to swell. Plants that are carrying an abundance of bloom should have the flowers thinned to twelve, or even fewer. Bring forward in gentle heat batches of plants to provide for a succession of fruits. Plants with berries that have just commenced to swell should be grown in plenty of atmospheric moisture, gradually increasing the temperature to 80° or 85° during bright days with top ventilation. This treatment may be maintained until the fruit commences to colour, when the temperature should be gradually lowered to 65° or 70°, with a freer circulation of air. Water should be afforded with extra care at this stage, for only sufficient moisture is needed to keep the foliage healthy and firm.

VINES.—The present month, or early in May, is generally considered to be the best time for planting young vines. Assuming that the border has been prepared properly in advance, select a dull day for the planting. "Cut-backs" that have made an inch or two of young growth should have most of the old soil shaken away, or washed from the roots, the latter spread out carefully and covered with a light dressing of soil. Do not bury the roots deeply, for in time the soil will settle, and this must be allowed for in planting. For several days afterwards shade the vines from bright sunshine, and syringe them several times during each day until the roots have made a fresh start. Maintain a moist, growing atmosphere, and a temperature of about 70° to 75°.

PINES.—The fruits will now progress much more rapidly than hitherto. Each plant should be examined regularly, and when moisture is needed the roots watered freely with weak guano water made tepid. If the bed in which the

plants are plunged is heated by hot-water pipes, and the material has become dry, take advantage of a fine day to moisten it thoroughly with tepid water. By doing this and damping the paths daily the atmosphere will be humid and genial, and the practice is far preferable to frequent syringings which are the ruin of many plants. Continue to treat successional plants as I advised in a former calendar. Encourage suckers potted recently to grow robust by giving them every attention. Maintain the bottom heat at 70° to 80°, and stand the plants close to the roof-glass, allowing sufficient space between each to prevent them becoming drawn and spindly. Syringe the plants very lightly once or twice a week at the time the pit or house is closed, which should be done when the temperature ranges from 80° to 85°.

THE KITCHEN GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

MUSHROOMS.—The last bed for the season may now be made of dimensions according to unoccupied space. Beds not yet exhausted may be helped by spreading a light dressing of soil mixed with a sprinkling of superphosphate evenly over the surface. Admit air freely when the weather conditions are favourable, and dispense with fire heat.

SCARLET RUNNERS.—A few plants may be started in pots to gain strength for planting out five or six weeks hence, or in very mild localities a few seeds may be sown out-of-doors. If the tops are pinched the plants will assume a branching habit and will fruit well without the support of sticks.

MUSTARD AND CRESS.—These salads will succeed now in the open. A suitable method of sowing is to scatter the seeds thickly on a small piece of newly-dug soil. After sowing, pat the soil with the back of a spade, so that the seeds are firmed, sprinkle with water, and cover with a piece of sacking till germination has taken place. Cress takes a week to ten days longer to grow than Mustard, and their sowing should be regulated accordingly.

NEW ZEALAND SPINACH.—Two or three seeds sown now in a 3-inch pot, and enough pots filled to plant what is required, allowing the plants 3 feet apart, will provide a stand by should Spinach fail, as it did last year, owing to drought and heat. The seedlings should have the protection of a frame till well established, and the plants require a few square feet each to develop after planting.

PLANTING ONIONS.—It is quite safe in most parts of the country to plant the early-raised Onions. Even if severe frost occurs the plants do not seem to suffer any bad effects. If the soil has been allowed to become rather dry in the boxes, the roots will be easy to separate. I like to draw the roots through a mixture of soil and water before planting, which usually gives the plants a start without having recourse to watering. For ordinary purposes, space the rows at 15 inches apart, and set the plants at 5 inches apart. Hoe between the rows after planting is completed.

SALSIFY.—This vegetable and Scorzonera are usually sown at this time. In my experience it is best to let the seed-sowing stand over for a few weeks, early sowing and "running to flower" being concomitants. If sown very thin—one seed to every 4 inches—the crop will need no thinning, and there is plenty of space at that distance alike for the roots and the top growth.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

CYCLAMEN.—Seedling Cyclamens are growing freely and may need shifting into 3-inch pots. Let the pots be well drained and place a layer of moss or other suitable material over the crocks. For soil use a mixture consisting of two-thirds loam and one-third leaf-mould, with a few lumps of charcoal, some sharp sand, and a little lime rubble or finely-broken crocks in

addition. Take care that the soil around the corm is moist before repotting the plant, and make the soil moderately firm. Stand the pots on a bed of ashes and syringe them in the early morning and again early in the afternoon, closing the house soon after midday to maintain a moist atmosphere and a temperature of 60° at night. These conditions should be maintained until the plants become established, but about the end of May they may be placed in cold frames close to the roof-glass. Shade from bright sunshine and fumigate the house or frame on frequent occasions.

CHRYSANTHEMUMS.—Plants intended to produce large blooms should be shifted into 6-inch pots before the roots become pot-bound. The compost should be mixed some days in advance of the potting, and may consist of three-parts loam, one part each of leaf-mould and manure from a spent Mushroom bed, and a little soot. Pot firmly, and stand the plants on an ash bottom in a cold frame. Spray the shoots overhead in the forenoon, but do not water the roots until moisture is absolutely necessary. Bush varieties may be treated similarly. When these plants are re-established pinch out the point of the growth to encourage side shoots to develop and repot as required. Green and black fly are very troublesome at this stage, and should be destroyed by dipping the plants in quassia extract or dusting the leaves with tobacco powder. If the leaf-mining maggot attacks the foliage pick off the worst infested leaves and burn them.

TUBEROUS-ROOTED BEGONIAS.—The main batch of plants of these handsome summer-flowering Begonias require shifting into pots from the boxes in which they were started. Begonias grow freely in a light, porous compost, such as a mixture of two-thirds fibrous-loam, and one-third each of leaf-mould (not too far decayed), and spent manure from an old Mushroom house, adding a little soot and sand. Lift the plants carefully from the boxes, taking care not to injure the mass of roots. The size of the pot must be determined by the size of the plant, and the receptacles should be well drained. Pot moderately firm, and return the plants to a warm pit or house shading them from bright sunshine. Syringe overhead in the early part of the day to allow time for the foliage to become dry before night, as excess of moisture on the foliage after dark may set up damping. Remove the flowers until the plants become established, and when strong enough to carry bloom feed the plants twice weekly with weak liquid manure.

THE "FRENCH" GARDEN.

By PAUL AQUATAS.

HOT-BEDS FOR CLOCHES.—Lettuces Little Gott grown on these beds should be removed as the Cos varieties are spreading their leaves and require increased space. Shade the crop from 10 a.m. till 3 p.m. on bright days; if the cloches are whitewashed for the purpose the wash should be applied on the south of the glasses only, but this system of shading is not to be recommended where only a few hundred cloches are in use.

UNHEATED FRAMES AND CLOCHES.—The crops in these beds require abundant ventilation daily, and watering every week. The Radishes have been marketed, and the removal of these and weeds will afford all the space for the plants of Lettuce Little Gott, which are forming hearts and will be ready for market within the next fortnight. The frames and lights will be removed from the variety White Passion in ten or twelve days, as this variety does not form good heads when grown under glass. It may be necessary to fix mats around the beds when the frames and lights have been removed, to shelter the crops from strong winds. Instead of shading the Cos Lettuces grown in these beds remove the glass on bright days.

MELONS.—These plants have grown freely during the past week or so, and ventilation may be afforded more freely than hitherto and over a longer period, but it is essential to spread dry straw or manure over the lights to break the rays of a glaring sun. Plants of the early batch

require increased space, and they should be syringed on all fine days. The ground allotted to the Melon quarter should be hoed or broken deeper if dug in winter. Fork over the black soil reserved for filling the frames. Mark out the space of the first bed, allowing for an 18-inch path on the outside, and 4 feet 6 inches width for the frames. Dig a trench 2 feet wide and 1 foot deep, and cart the soil to the bottom end, to be utilised for fitting the last row. Have ready a supply of fresh manure for making the hot-bed, allowing about three tons for every bed of fifteen lights. If the frames are intended for growing a crop of Vegetable Marrows the plants should now be in 4½-inch pots. Afford the plants plenty of space, abundant ventilation, and copious waterings. They should be set out in ten or twelve days time. Meanwhile, prepare the beds by digging a trench 12 inches wide and 12 inches deep, to be filled with good hot manure that should be soaked with water to hasten fermentation. Place the soil of the second trench on the top of the manure, and set the frames so as to have the trench just in the centre. Place three barrowloads of black soil in each frame as a top-dressing, and then place the lights in position. About the third week of April set six plants very deeply in each frame to within 2 or 3 inches of the manure. When the roots are well established ventilation and water may be afforded. It is essential that the frames be covered at night with mats.

PUBLIC PARKS AND GARDENS.

By SUPERINTENDENT.

GROUNDWORK.—As far as practicable all groundwork improvements should be finished for the season and the surface of the soil either turfed over or sown down with suitable grass seeds. With the unusually mild and damp weather grass has been readily established, indeed that in the London parks has rarely been seen in better condition than at the present time. Should the weather continue damp both seed sowing and turfing may still be engaged in, but after the end of May it is rather a hazardous proceeding, for should a spell of warm and dry weather set in both seed and turf would suffer in consequence.

RENOVATING HEDGES.—Deciduous hedges if cut back at once will soon become green. Where the soil along the line of hedge has become poor an application of thoroughly decomposed manure will greatly improve the appearance and strength of the plants. It should be spread along the surface and gently forked amongst the existing soil, great care being taken to prevent injury to the roots of the shrubs of which the hedge is composed. Blanks in the fence may at the same time be filled up by using stout, bushy plants of a similar kind to those of the hedge. Shrubberies should likewise receive attention in the matter of necessary pruning and digging. Recently-transplanted trees and shrubs must be examined, and those loosened by the wind made firm by treading.

GENERAL WORK.—Roads and paths should be maintained in a thoroughly efficient state, the former being kept in good surface and the latter smooth for pedestrians. When about to apply gravel to paths the surface should first be lightly picked over, so that the material may adhere firmly to the original roadway. Sand or pounded cockle shells make excellent path surfaces, and should be applied preferably after rain. A light application is all that is necessary, the surface presumably being in a fairly even and sound condition previous to the application. Compost heaps should be turned over and a quantity of fresh lime added, this not only depriving seeds of their vitality but helping to sweeten the mixture. When thoroughly rotted, weeds, leaves, and road sweepings make excellent manure, especially when mixed with a small proportion of unslaked lime. General tidiness should be maintained, the paths kept free from weeds and dirt, shrubberies dug over, lawns neatly mowed, and roads and foot-paths edged and cleared of any overhanging branches which obstruct visitors.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are mis-directed.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, APRIL 21—

Roy. Hort. Soc. Coms. meet (Nat. Auricula and Primula Soc. combined Show.) (Lecture at 3 p.m. on "The Probable Origin of Existing Flowering Plants.") Lincolnshire Daffodil Soc. Show.

WEDNESDAY, APRIL 22—

Herefordshire Spring Fl. Sh., Shire Hall, Hereford. Darlington Hort. Soc. Spring Fl. Sh. in the Corn Exchange.

THURSDAY, APRIL 23—

Nat. Rose Soc. Spring Ex. at R.H.S. Hall, Westminster. Midland Daff. Soc. Sh. at Birmingham (2 days). Roy. Botanic Soc. meet.

AVERAGE MEAN TEMPERATURES for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 48.5°.

ACTUAL TEMPERATURES:—

LONDON, *Wednesday, April 15* (6 p.m.): Max. 59°; Min. 42°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday, April 16* (10 a.m.): Bar, 30°; Temp. 52°. *Weather*—Sunshine.

PROVINCES, *Wednesday, April 15*. Max. 51°. Yarmouth; Min. 45°. Aberdeen.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Liliums and other Hardy Bulbs, at 12; Roses and Carnations, at 1.50; Palms and Plants, at 5, at 67 and 68, Cheapside, E.C. By Protheroe and Morris.

WEDNESDAY AND THURSDAY—

Unreserved Clearance Sale of 1,900 Orchids and other stock, at Dover House, Rochester, by order of the executors of the late J. Pierpont Morgan, E-q. By Protheroe and Morris, at 12.

The Daffodil Season.

The Daffodil season of 1914 has followed on a winter of unusual mildness, as did the season of 1913, but so far as can be seen at present the two seasons will prove very different in character. In 1913 the earliest Daffodils out of doors, Pallidus Praecox and minimus, made their appearance about the 26th of January, whilst the early Trumpets, Henry Irving, Golden Spur, and Tenby, came into flower during February. By the end of March many of the mid-season varieties were in bloom, but curiously enough as the season progressed this precocity of opening was not maintained, and the varieties which flower late came into flower at dates not far removed from their normal period of opening. For some reason, which is not easy to explain, the present season has so far shown itself rather later than usual, and much later than its predecessor. Pallidus Praecox and minimus did not open until the end of February, while March was

half-way through before the bright yellow flowers of Henry Irving and Golden Spur or Tenby were to be seen, and even at the end of March only a few of the early varieties had opened. It is true the bright sun of the first few days of April brought out many of the garden Daffodils with a rush, not altogether to their advantage as show flowers, and now in the middle of April the many Daffodils in flower, though perhaps decidedly later than in 1913, are not far from normal in their time of blossoming. It may be urged that the lateness of the present year has to some extent been brought about by the dryness of the ground throughout the summer and early autumn of 1913, but such an attempt at explanation is little better than a cloak to conceal our ignorance.

Although the early flowers have suffered somewhat in the garden from the copious and persistent rains of one of the wettest Marches on record, there have been some very fine flowers exhibited at the Horticultural Hall. The season may be said to begin with the forced-bulb show, which took place this year on the 10th and 11th of March. The flowers exhibited at that early date were the products of protective culture, and were almost independent of weather conditions, but the fine flowers exhibited since that date from plants grown in the open show how, with a little care in gathering, the Daffodil may be had in perfection in spite of inclement weather.

An interesting event early in the season was the exhibition by Messrs. Barr and Sons of flowers of a new class of hybrid Narcissus similar to the Poetaz and probably crosses between the Poeticus and Tazetta or Polyanthus sections, as were the original Poetaz introduced by Van der Schoot. This new class of Poetaz appears to be rather nearer the Polyanthus parent, but with somewhat larger or at least more noticeable cups. Like this parent, it is not unlikely that they may prove chiefly valuable for forcing, but until they have been tried out-of-doors in this country a final opinion on this point must be reserved. It is a coincidence that Mr. Wilson is at the same time showing us illustrations of varieties of a similar cross, but nearer Poeticus; Rubellite is one of these with a brilliant cup and about a couple of flowers on the stem.

The Narcissus Committee has made a new departure this year in giving awards to Daffodils suitable for special purposes. The variety W. P. Milner was given an award as specially suitable for rockwork, and for this purpose as well as for growing in pots this charming little flower is well adapted; but one wonders why minimus and cyclamineus varieties pre-eminently adapted for this purpose were overlooked. Olympia received an award as specially suited for growing in pots. It is a fine and richly coloured Trumpet for the garden. At the later show at the beginning of April awards were given to Tantalus, a very large Leedsii, and Inglescombe, a really beautiful double of a charming shade of soft canary-yellow, as suitable for cutting; Croesus, a big

Incomparabilis somewhat of the White-well type, received an award as specially suitable for the garden. It is evidently a tall flower, and one immediately inquires—Can it stand wind? if so, the award is justified. For show purposes awards were given to Ivorine, a particularly beautiful creamy-white flower with an expanded, almost flat cup, and not too big; Royal Sovereign, a double; White maximus, a pale sulphur edition of the well-known and rich coloured maximus; and Queen Primrose, a trumpet which holds its head up, or rather out, from the stem, and is of the colour indicated by the name. These awards to Daffodils suitable for special purposes are certainly a step in the right direction; they will, however, be of little service to amateurs and the public if the awards for excellence in the garden and on wallwork are confined to varieties brought before the Committee at the shows. Nor will any awards to new varieties not likely to be popularly distributed for 10 or 15 years be of much immediate value. If the members of the Committee will go into their own and their friends' gardens, and note the large perianth forms capable of standing a wind or a bleak hillside, and will carefully compare and classify their observations, the results would prove of considerable value.

The new varieties exhibited have been many and good. Northern Queen is a particularly beautiful Leedsii, with a well-filled rounded perianth and a pale yellow cup, while all who have attended the recent dinners of the Horticultural Club will remember the pleasing vases filled with Queen of the West, a trumpet flower of a soft self yellow. In the garden a self flower, that is, one with the perianth of equal colour with the crown or trumpet, is always striking; it is to this tint that Homespun owes its value, and Queen of the West, when it can be grown in quantity, should have a long reign in the garden. Sparkler, though not new, is worth notice as perhaps the earliest of the red cups to come into flower out-of-doors. A particularly fine Leedsii with a cup like a trumpet has appeared in Capella, and while recalling the cream-coloured forms, perhaps few have been more attractive than Carmenta, a large flower, but refined in form, of the type called Giant Leedsii, the perianth creamy-white, with the crown very pale yellow.

Mr. Engleheart's garden continues to produce wonderful flowers of all sizes and types, so many, in fact, that he has shown most of them unnamed. Some particularly large and fine coloured Trumpets were to be found in these exhibits, one of which, at first called Dinton (though it is said the name has been since changed), was very striking. Size of flower is a quality always fostered by flower shows, whether of Daffodils or Roses, and to such an extent that even the most careful have sometimes to remind themselves that the true end of the gardener should be beauty and not gross culture, however difficult may have been the task by which such culture is attained. This reflection was aroused by a little vase of quite small flowers of a variety called Dewdrop, ex-

hibited by Mr. Bourne at a recent show. Each little flower was perfect of its kind, beautiful in form and graceful in pose, while the creamy-white colour and tasteful arrangement of the vase gave to the whole a most delicate and refined appearance.

Lavender is another flower of very attractive and delicate tint. It might almost be described as a study in "art" colours, the prevailing tint in the cup being a soft terra-cotta with a suspicion of lavender in the edge.

It is impossible to get up enthusiasm over a mere number, and so it is usually best not to refer to varieties merely indicated in this manner and shown without a name, but an exception may perhaps be made in favour of one or two *Jonquilla* hybrids similar to *Buttercup*, though of a deeper colour, and stated to flower earlier than that variety. When the time arrives that varieties of this fine colour can be planted in quantity in our gardens, they should produce a good effect. Judging, however, from the price at present asked for *Buttercup* we seem to be looking forward to a sufficiently distant future. Some few years ago a gentleman of great experience in these matters gave it as his opinion that the high prices then being asked for new seedling *Daffodils* could not be maintained. Since then the

period has the number of beautiful new forms been greater than it is at present. The supply, however, appears to have in-

is apparent. It has, however, probably led to a more rapid discarding of inferior forms and poor growers.

FIG. 118.—*SYRINGA PINNATIFOLIA*: FLOWERS WHITE.

FIG. 119.—*OSMANTHUS DELAVAYI*: FLOWERS WHITE.

(R.H.S. Award of Merit, April 7, 1914.)

number of raisers of new varieties have increased yearly; and perhaps at no

present no indication of a fall in prices

A satisfactory feature of some of the *Daffodil* shows this year has been the endeavour to get rid of the formal and bank-like arrangement of groups hitherto adopted. The experiments in this direction made by Mr. Bourne, Messrs. Barr and Messrs. Carter have each in its way been interesting and have lent an additional attraction to these several exhibits.

Coloured Supplement.—The subject of the coloured plate to be published with the issue for next week is a terraced pergola exhibited at the Royal International Exhibition, Chelsea.

NEW CHINESE SHRUBS.—Trees and shrubs have formed a considerable proportion of the large numbers of new plants sent home by collectors in China during the past few years, but up to the present they have not seemed of such importance as the new border flowers from that source, because a long time must necessarily elapse before hard-wooded seedlings reach the flowering stage. However, many of the shrubs have already blossomed, and at the meeting of the Royal Horticultural Society on the 7th inst. three of the newer species were exhibited in flower by the Hon. VICEY GIBBS. Two of these are illustrated on this page. The spray of *Lilac* (*Syringa pinnatifolia*) shown in fig. 118 is reproduced in natural size, and was taken from a plant about 4 feet high growing in a pot. The foliage is divided into four or five pairs of small glabrous, bright-green leaflets, each about $\frac{1}{2}$ inch long. The flowers are white and borne in short racemes, not unlike those of species of *Ribes*. *S. pinnatifolia* forms a neat bush, and will be valued for its decorative effect in spring. *Osmanthus Delavayi* (fig. 119) is evergreen, grows about 18 inches high, and is therefore a good subject for planting on rockeries. The white flowers are borne in dense clusters and possess a delicate scent. The small, dark green, ovate leaves have serrated margins, and are not so long as the tubular flowers, which appear in clusters in the leaf axils.

HORTICULTURAL CONGRESS, PARIS.—The 26th congress organised by the French National Horticultural Society will be held in Paris, in the Society's Hall, 84, Rue de Grenelle, at 9 a.m. on Friday, May 22. The subjects discussed will include workmen's gardens; the influence of radio-activity and of catalysis on plants; co-operation in the sale of horticultural produce; new methods of heating, glasshouses by hot water, steam, waste heat or electricity; deleterious effects on plants of smoke and harmful gases produced by factories.

NARCISSUS SEEDLINGS.—Mr. A. J. BLISS has succeeded in raising some pretty little hybrids from *Narcissus triandrus albus* crossed with the pollen of the Jonquil. The flowers are a clear lemon or canary-yellow, and have that peculiar clearness of petal which is characteristic of so many triandrus hybrids. They grow from 9 to 12 inches in height, and some partake rather of the character of the seed parent in colour and habit, whilst others approach more nearly the pollen parent in appearance. They should make charming little plants for a patch in the rock garden. A pleasing feature about them is that they appear to have retained the delightful fragrance of the Jonquil. Mr. BLISS states that this particular cross has not yet, to his knowledge, been exhibited.

INTERNATIONAL HORTICULTURAL EXHIBITION AT PARIS, 1915.—The general committee to be entrusted with the organising of the great exhibition to take place in Paris next year has just been appointed by the French National Horticultural Society. It is divided into four sections, the first to take charge of the Congress and receptions, the second to arrange the programmes, prizes, classes, etc., the third to manage the advertising, and the fourth to make arrangements for subsidies and special prizes.

NATIONAL ROSE SOCIETY.—The spring exhibition of the National Rose Society will be held on the 23rd inst. in the Royal Horticultural Society's Hall, Vincent Square, Westminster. The Society's Gold Medal is offered for the best group of pot Roses staged by a nurseryman, and raisers are invited to submit new varieties, for which Gold Medals, Silver-gilt Medals, or Cards of Commendation will be awarded, according to merit. Money prizes are offered in the other 25 classes.

NATIONAL AURICULA AND PRIMULA SOCIETY (SOUTHERN SECTION).—The exhibition of the National Auricula and Primula Society will be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Tuesday, the 21st inst. Entries must be sent in at least four clear days before the date of the show. The James Douglas Memorial Challenge Cup is offered in class 14 for twelve Alpine Auriculas, and not in class 1, as stated in the schedule. The secretary is Mr. T. E. HENWOOD, 16, Hamilton Road, Reading.

FORESTRY: NATURAL REGENERATION.—Lectures on Forestry delivered recently at Fochabers, Morayshire, by Mr. LESLIE, of the Aberdeen and North of Scotland College of Agriculture, evoked an interesting discussion by Mr. MURHEAD, Commissioner to his Grace the Duke of Richmond and Gordon, Gordon Castle, Mr. LESLIE, Mr. SHARP, Mr. JONES and others. The chief point debated was the natural regeneration of forests, the speakers contending that forests should be allowed to re-plant, or rather re-sow, themselves. It was pointed out that if forests were enclosed by close wire-fencing and game kept out, seedlings would spring up naturally and obviate the need for planting.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.—The spring show of this society will be held in the Waverley Market, Edinburgh, on the 29th and 30th inst. On the first day members of the society will be admitted at 12 noon, one hour before the general public. The secretary is

Mr. DONALD MACKENZIE, 23, Rutland Square, Edinburgh.

PERPETUAL-FLOWERING CARNATION SOCIETY.—The provincial spring show of the Perpetual-flowering Carnation Society will be held in the Bournemouth Winter Gardens Pavilion on the 29th and 30th inst. The show will be opened by the Mayoress of Bournemouth on the 29th inst. at 2 p.m.

ENTOMOLOGICAL SPECIMENS REQUIRED.—Mr. C. NICHOLSON, of 35, The Avenue, Hale End, Chingford, is requiring for purposes of scientific investigation a few larvae of the small Narcissus fly (*Eumerus strigatus*), cocoons of the Pine saw-fly (*Lophyrus pinii*), and a good supply of larvae of the large Narcissus fly (*Merodon equestris*), also cocoons of the large Larch saw-fly (*Nematus erichsonii*). Perhaps some of our readers may be able to furnish Mr. NICHOLSON with specimens of some of these pests, and he will refund the postage on any that may be sent him.

ROYAL METEOROLOGICAL SOCIETY.—A meeting of the Royal Meteorological Society will be held at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 22nd inst., at 7.30 p.m. The following papers will be read:—(1) "Report on the Phenological Observations for 1913," by J. E. CLARK, B.Sc., and R. H. HOOKER, M.A.; (2) "A Small Anemometer for Tropical Use," by A. J. BAMPFORD, B.Sc.

CHRYSANTHEMUM CONGRESS AT MELUN.—In conformity with the decision arrived at on the occasion of the congress at Nantes, and confirmed by that at Ghent, the nineteenth annual Congress of the Société Française des Chrysanthémistes will be held at Melun. The date is not yet definitely fixed, but the Congress will be held early in November next. The horticultural societies of Seine-et-Marne are meanwhile preparing an exhibition of all kinds of horticultural produce, to be opened at the same time. An excursion to the Palace of Fontainebleau, with the magnificent Park of Vaux-le-Vicomte, which was designed by Le Nôtre, will close the Congress.

WOMEN'S NATIONAL AGRICULTURAL AND HORTICULTURAL ASSOCIATION (U.S.A.).—A National Association of women interested in horticulture and agriculture has been formed in the United States. The objects of the association are the exchange of information among its members; to bring together supply and demand both of produce and of labour, and to increase the knowledge and use of existing institutions. As a means to this end it is hoped that a general secretary may be employed, conferences of a practical nature may be held, local exhibitions encouraged, and printed matter distributed. The president is Mrs. FRANCIS KING, Alma, Mich.; corresponding secretary, Mrs. SUSAN H. VOLLMER, Huntington, N.Y.; and treasurer, Miss LOUISA G. DAVIS, Ambler, Pa. Affiliation with the Women's National Agricultural and Horticultural Union of London is under consideration.

AMERICAN GOOSEBERRY MILDEW.—The Board of Agriculture and Fisheries has received information that the summer stage of American Gooseberry mildew (*Sphaerotheca Mors uvae*) was discovered in a Cambridgeshire garden on the 6th inst. All Gooseberry growers are advised to examine their bushes carefully, and should any sign of disease be found to spray their bushes with a solution of liver of sulphur (one pound to 32 gallons of water). A leaflet describing the disease and giving directions for dealing with it can be obtained from the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W., gratis and post free. Letters so addressed need not be stamped.

FLOWERS IN SEASON.—Mr. C. G. VAN TUBERGEN, jun., of Haarlem, who has already

exhibited in this country variously-coloured hybrid Freesias, has sent us a collection of flowers representing a fresh batch of novelties, each variety being named. Taken collectively, they show a considerable increase in the diversity of colouring, and many of the flowers are improved in size as compared with the earlier representatives of this section. The varieties are as follows:—Doreen, rich yellow, with orange flush on the lower segments; Dulcinea, pale lilac and white, flowers rather small; La Surpassante, rose-colour and white; Robinetta, small white flowers, the points of the segments reddish-purple, the petals very beautifully lined; Canari, yellow and cream; My Pet, pale greyish-mauve, the colour one sees in *Mackaya bella*; Heliotrope, a shade of purple; Contrast, white, with bright orange on the lower segments; Dainty, bright purple with silver underneath; Monette, a very large, open flower, white and pale mauve, with bright orange at the base of the segments; Charmante, pale salmon-rose and Conquest, purple and white.

—Mr. F. DENIS sends us flowers of a hybrid *Ophrys* he has raised from a cross between *O. tenthredinifera* and *O. aranifera*. The first-named species is the seed-parent. The flowers of the hybrid vary considerably, ranging between the two natural hybrids *O. Grampini* and *O. Etrusca*, which are admitted to be derived from the same parentage. The new hybrid flowers very early, at the same time as *O. Battandieri*, the result of a natural cross between *O. ineca* and *O. lutea*. Flowers were exhibited before the Société Nationale d'Horticulture de France in March, 1912 (see *Orchid Review*, July, 1912).

HIPPEASTRUMS.—Lecturing before the Royal Horticultural Society on Tuesday, April 7, Mr. FIELDER gave an interesting account of the history and cultivation of Hippeastrums. He mentioned that hybrids of these plants were first raised in 1790 by Dr. GRAFF, and referred to the many raisers in this country who have taken part in this work. Mr. FIELDER pointed out that amateurs need not deprive themselves of the pleasure of growing these plants since the popular idea that Hippeastrums must have considerable heat is erroneous. A temperature of from 55° to 60° suffices, and bottom heat may be dispensed with. New varieties may be raised from seed and good strains may be continued by off-sets. A noteworthy observation was that in the experience of the lecturer off-sets do not appear to be formed from bulbs which have themselves grown from off-sets. For flowering in winter Mr. FIELDER advised the use of the less choice varieties, for when treated in this way the bulbs wear out quicker. He remarked that bulbs which have been forced go into the resting stage earlier than they would if they had been grown in their natural season. With respect to the raising of seedlings, Mr. FIELDER urged that if seed be sown as soon as it is ripe (in June or July), and if the seedlings be grown on instead of rested during the winter, flowers may be produced in one year and nine months. Those who are wont to receive bulbs of Hippeastrums from the East should impress on the senders the need for lifting and despatching the bulbs only during the resting season. The practice of the inexperienced traveller on seeing a taking flower is to lift the bulb forthwith, and to despatch it on a long journey without any special treatment. An interesting statement was made in the course of the discussion that bulbs of Hippeastrum sent from Malaya bear during their first year or so in this country leaves and flowers simultaneously, but that after a longer or shorter period the leafless bulb throws up its flowering shoot and the bulbs deteriorate. Whether this is due to improper cultural treatment during the resting period—too complete dryness, for example—or whether it is due to the bulb endeavouring to recall its normal habit in the less propitious circumstances of a temperate house we do not know. As Mr. FIELDER insisted, the amount of

water should be reduced during the time the bulbs are ripening, and after resting over winter in a temperature of 40° or 45°, the bulbs, when started in spring, should receive little water for the first ten days, during which time growth begins.

SOME RECENT EXPERIMENTS IN THE APPLICATION OF ELECTRICITY TO PLANT PRODUCTION.

(Concluded from p. 247.)

A MUCH more difficult problem is presented by the need for a control area under normal electrical conditions, and yet close to the electrified area, so as to avoid differences in soil and exposure. This need for proximity renders it almost impossible to obtain a complete control. Winds cannot be avoided, and in a wind the electrically-charged air over the electrified area must move away from the wires in the direction of the wind. Something can be done by placing the control to one side of the electrified area, and if there is a direction from which the winds usually blow, to put the control on this side of the electrified area.

Some advance towards the solution of the problem was made at Dumfries in 1913, and the arrangement as adopted there is shown in the diagram (fig. 120). It will be seen that the electrified area lies to the north of the control, which is the direction from which in both 1911 and 1912 winds had most rarely come. Potatoes were grown again in this year, and again gathered and weighed from small areas, either one-tenth or one-eleventh acre in extent; the different areas weighed are numbered in the plan. Between the control area and the last overhead charged wire there intervenes a space of twelve yards. Across this space stretches a network of galvanised iron wire of 1/2-inch mesh 10 feet high. This network is earthed at intervals, and was intended as a screen to cut off some of the discharge from the electrified area. For purposes of comparison one-tenth acre of the control, No. 4, was completely enclosed in a cage of the same material 6 feet high. The main wire screen was not in place until June 28; by that time the horse labour upon the crop had finished. In another year it is intended to have it in place earlier. The result of interposing these screens was studied by various electrical methods, and it was found to have some effect, but not enough.

There was clear evidence that with this height (10 feet) of screen, as compared with the height of the charged wire (about 14 feet), a very large amount of the discharge came over the top of the network, and on days when the wind blew from the north with any vigour it was impossible to continue the discharge.

Unfortunately the weather was very exceptional in 1913 in this locality, very dry, with frequent winds from the north, so that the occasions when the control was not efficacious were far too numerous. The season of 1914 will see further attempts to get a satisfactory control. The relative heights of the charged network and the wire screen are being changed to try to cut down the leakage of the electricity over the screen, and other methods are being tried which it is not necessary to describe until their efficacy has been tested.

It is unfortunate that the value of the control obtained for the latter part of the season at Dumfries cannot be assessed in the light of the weight of Potatoes obtained during this year. That this cannot be done with fairness is owing to the abnormally dry season. As was pointed out before, dry weather is unfavourable to electrical treatment, and the whole district sustained one of the driest seasons known for years. From June 13 until August 20 only 1.54 inches of rain fell, and there were fifty days within this period without any rainfall. Under these conditions lack of moisture was the limiting fac-

tor all over the field and undoubtedly determined the very small yields obtained. The yields per acre by the different plots is given in the table below, and in all cases where on either side the yields are better the reason is a slightly deeper soil holding more moisture. The plots just to the north of the wire screen which were not weighed were in the same slight hollow as Nos. 12 and 13 of the control, and these unweighed plots undoubtedly cropped heavier than any other portion of the field.

In 1914, with normal weather, some important figures should be obtained. The control at Dumfries, if not all we might desire, will certainly be better than in 1913, and the electrical comparison between the two areas will be de-

These experiments have been briefly described, but so far they have not been fully followed up, because the special working conditions involve many new problems, which require special consideration.

Insulation is the great difficulty in the glass-houses, and the impression of the present writer is that critical electrical tests would show that up to the present no satisfactory experiments have been carried out in greenhouses, but that the discharge has been impartially distributed upon the many earthed conductors, from supporting wires to hotwater pipes, waiting to receive it. It is hoped to return to this problem later if the results of the trials under the conditions in the open seem to justify it, and indeed some small experiments are now in progress in a greenhouse. In the long run, if increased yields can be expected, then the outlay in apparatus would

TABLE OF YIELDS (DUMFRIES EXPERIMENT).
The number of the plots refers to the diagram shown in fig. 120.

Average 7.31 tons per acre.

probably be most justifiable in the intensive practice of the horticulturist. But for the present, until the actual question of yields under different treatment is settled, the actual crop under treatment is rather a matter of convenience than anything else. When once the general principles of the methods are understood the application of these principles to the electrification of crops is a comparatively simple matter.

In conclusion, a word to the reader who feels that progress is slow. We are dealing with a problem that has been more or less under investigation since 1750, and in which all hasty work has only succeeded in confusing the issue. Nothing will be gained by hasty generalisation on ill-considered, insufficiently-repeated experiment. The apparatus and method of treatment involve considerable expense, and the large-scale trials in which controls have to be obtained have involved many difficult and tentative experiments. Hasty decision invariably means repentance at leisure. Especially must it be remembered that we are still applying a very little understood power to affect the development of an organism the interior and essential processes of which are still largely unknown to us. Little wonder, therefore, that progress is slow, is accompanied by much destructive criticism of earlier work, and is unaccompanied by any confident predictions. J. H. Priestley.

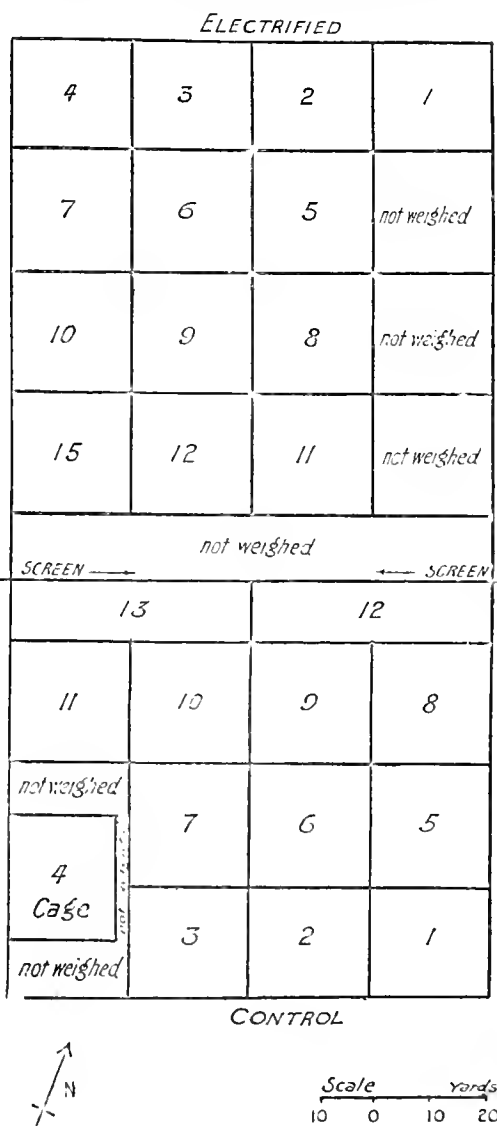

FIG. 120.—CONTROL AND ELECTRIFIED AREAS.

finite. Furthermore, Mr. Low is also putting up a lofty wire screen in the Balmakewan experiments, and, with good fortune, both should be conducted in weather that will not prevent the detection of the value of electrical treatment. Therefore 1914 should go far to settle the practical point at issue. But there must always be this proviso, that until more laboratory results come in we shall still be working in the dark.

Nothing so far has been said about the application of electrical discharge under greenhouse conditions. It is impossible to do justice to this subject in the space of a brief article, as the greenhouse conditions introduce many new problems which require detailed discussion.

Attempts have been made to apply the discharge in greenhouses at Bitton, near Bristol. The crops chiefly treated being Tomatoes and Cucumbers grown commercially (see fig. 122).

NOTES FROM WISLEY.

PLANTS IN FLOWER.

A LARGE bush of the graceful evergreen Chilean shrub, *Azara microphylla*, is covered with small yellow flowers, which diffuse a most pleasing Vanilla-like fragrance. The specimen, which is about 12 feet high, is protected from east winds by a belt of Austrian Pines. The fine tree of Weeping Cherry (*Cerasus sinensis pendula*) is in full flower, and covered with delicate pink blossoms. On the far side of one of the larger ponds a tree of *Salix babylonica* is very effective at the present time. *Forsythia suspensa*, *Ribes sanguineum* and *Nuttallia cerasiformis* are flowering freely in the garden. Camellias are blooming in the wild garden, and on the shrub border by the glasshouses *Ribes speciosum*, with its deep-red Fuchsia-like blossoms, is very attractive, whilst *Corylopsis spicata* is opening its spikes of Cowslip-scented flowers. Large numbers of Primulas and Daffodils are flowering in the wood. Of the many plants in flower in the alpine house the following are especially noteworthy:—*Epigaea repens*, with wax-like, faintly-scented rose-tinted blossoms; *Anemone palmata*, *A. fulgens*, *Aubrietias* Dr. Mules and Lloyd Edwards, *Primula frondosa*, *Narcissus Bulbocodium*, *N. juncifolius*, *Thalictrum anemonoides*, *Sanguinaria canadensis*, *Morisia hypogaea* with bright yellow flowers, and *Saxifraga afghanica*, of which a large plant carrying many spikes of pink flowers makes a striking feature.

SCOTLAND.

SUPERINTENDENT OF ABERDEEN PARKS.—At a meeting of the Aberdeen Town Council, held on the 6th inst., a recommendation by the Links and Parks Committee that Mr. Robert Walker should be appointed general superintendent of the city parks was adopted. Mr. Walker has been for 42 years in the employment of the Corporation of Aberdeen. His first appointment carried with it a salary of only £52 per annum, and the most recent one, that of Superintendent of Victoria Parks and several other parks and open spaces, had attached to it a salary of £170. The new appointment, which involves the duties of a general superintendence of all the parks, golf courses, children's playgrounds, etc., has a salary of £200 per annum.

GRANTS TO HORTICULTURAL SOCIETIES.—Aberdeen Town Council has again voted money grants to the two local horticultural societies. The Royal Horticultural Society of Aberdeen receives £10 10s., and the Aberdeen Chrysanthemum Society £5 5s.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

RAINFALL.—The rainfall here in February amounted to 6.65 inches; and in March, 6.90 inches. Rain fell on twenty-two days in February and twenty-five days in March. Our gauge is 240 feet above sea level. *W. Mann, The Observatory Gardens, Penllergare, Swansea.*

—During March rain was registered here on 30 days out of the 31, and the total was 8.98 inches. The greatest fall was on the 21st, when 1.10 inch was recorded. In February rain was registered on 20 days, the total being 8.16 inches. *George Laurence, Manor House Gardens, North Bovey, Moretonhamstead, Devonshire.*

MISTLETO ON THE COMMON HAZEL (see p. 240).—My friend, Mr. Crump, will be interested to hear that many years ago I found the Mistletoe growing upon a branch of the common Hazel overhanging the trout stream, which,

as he will recollect, passes near to the Hendre kitchen gardens. Subsequently rabbits destroyed the bark of the Hazel's stem, and killed the branch, together, of course, with the Mistletoe. If my memory serves me rightly I asked at the time in the pages of the *Gardeners' Chronicle* if Mistletoe found growing upon the Hazel was a rare occurrence, and Mr. A. D. Webster replied that he had seen an instance of it. *Thos. Coomber, The Hendre Gardens, Monmouth.*

—I have known for many years past a case of the Mistletoe growing on the Hazel in one of

FIG. 121.—MEASURING THE ELECTRIC DISCHARGE, GARFORTH.

On the right the candle within a wire cage supported on an ebonite rod. The candle takes up the potential of the air at the point its flame reaches; a wire carries the charge to the electrometer standing on the glass plate. The observer then determines the voltage by the deflection of the aluminium leaves of the electrometer.

(See p. 271.)

the Cobham Hall woods in Kent, though when I last saw it the Mistletoe was decreasing in size. On the Maple there I have seen growths 9 feet long, but the finest specimens I have seen were on Acacia, the clumps being 5 feet through, mea-

FIG. 122.—ELECTRIFIED CUCUMBER HOUSE AT BITTON.

One charged wire runs down middle of house, and is suspended from insulator attached to each door. When the house is entered the wire sags to ground and so avoids danger of shock. The photograph makes clear the waste of electricity to poles, supporting wires, water pipes, etc.

(See p. 271.)

sured after being blown out by a storm. I have seen it growing in Kent on the following trees: Black Poplar, Lime, Ash, Elm, Acacia, Medlar, Apple, Pear, Crab, Thorn, Blackthorn, Maple, Hazel, and Plane. *T. R. Cuckney, Arnside, Carnforth.*

THE NARCISSUS FLY.—I should be sorry if the expression of my hopeful opinion in my note on March 28 regarding the *Eumerus lunulatus* should cause anyone to relax his precautions against it while still *sub judice*, and I hope that Mr. Charles E. Shea (see p. 240) will counteract any such effect. My object was rather to put forward an alternative view, which the results of my experience seemed to strongly support, in order that it may be tested by anyone carrying out a thorough scientific investigation. For my part, while we are still in a state of uncertainty, acting on the principle of "he's a stranger, heave half a brick at him," I take up all doubtful bulbs (so far as I have time and opportunity) and destroy all grubs and flies that I can capture. The case for the view that the *Eumerus* is a scavenger is, however, I think, stronger than Mr. Shea will allow. Insects, like fungi, which feed on living tissue, are generally specialised for a particular species or kind of plant, or group of more or less closely allied species. Whereas insects which live on dead matter, like saprophytic fungi, can attack a much wider range of substances, provided only that these substances are in a suitable state of decay. It seems, therefore, very unlikely that a grub could vary its habit and diet so widely as to feed both on the living bulb of a Daffodil (*Amarylidaceae*), and on the rhizome of an Iris. Still more, that it should be alternatively a feeder on living or dead matter. On the other hand, if the *Eumerus* is a scavenger it might very well be expected to be found in a rotting Daffodil or Iris, or any other convenient rotting plant tissue. A further experience, not mentioned in my note of March 28, is that in a plot containing some 400 special Daffodil bulbs, which for convenience of crossing were all numbered, and a plan kept, I did not lose a single bulb from 1907, when they were planted, until 1910, when the *Merodon* first appeared; and 1911, when the *Fusarium bulbigenum* was so prevalent, although there were numbers of *Eumerus* about in 1908 and 1909. During the same period in my selection plots containing over 700 poeticus seedlings only 8 bulbs were noted as "dead" (cause unspecified). There is another point that Mr. Shea appears to have overlooked which I wish to draw attention to, all the more as it gives an opportunity of suggesting a practice which would be advisable whether the *Eumerus* be a scavenger or not. The *Eumerus* grub matures in a much shorter period than the *Merodon*. I do not know how many broods there may be in a year, but there are certainly more than one, and possibly three. The grubs found in bulbs now will be soon pupating, and will form the first brood. Some *Eumerus* grubs found in bulbs taken up at the end of June pupated in July, and developed into flies in the first days of August (perhaps prematurely from having been disturbed). The grubs found by Mr. Shea in his bulbs must have come from eggs laid by this second (or a still later) brood. But by this time all Daffodil foliage is gone. There would have been no leaves (of any particular bulb) for the fly to lay its eggs on as Mr. Shea suggests. Either the fly must have found a hole above the neck of the bulb, if a healthy one, or in some way can scent out a bulb that is rotting and deposit its eggs above the spot. As for the bulbs having been absolutely strong and healthy last year, a bulb attacked by *Fusarium bulbigenum* may be apparently quite healthy, may flower and even seed, and yet be diseased throughout and rotting by October. It would appear, then, that if the soil is raked over and the holes left by the decaying leaves and stalks are filled up as soon as the foliage has died down the healthy bulbs would be protected, at any rate from the later broods of the fly, if not altogether. *A. J. Bliss.*

THE QUINCE AS A FLOWERING PLANT.—Writing in *Mollers Deutsche Gärtner Zeitung* (No. 13, 1914), Mr. B. GOERTH, of Proskau, extols the beauty of the Quince as a flowering "shrub." He points out that the Quince does well in grass, and the large-flowered varieties present a beautiful sight when in blossom. Among the varieties of *Cydonia vulgaris* which Mr. GOERTH recommends are:—Badener, Champion, "Mammut" (Mammoth), Riesen Quince (Giant Quince) of Leskovac, Persische Zucker Quitte, and FULLER'S Birn Quitte (Pear Quince).

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 15 AND 16.—The special competitive Daffodil Show, which was held at the Vincent Square Hall on these dates, was very successful. There were numerous exhibits, most of the blooms were good, and in many instances the competition was keen. More than 50 seedling varieties were submitted to the Narcissus and Tulip Committee for award, and of these eight received Awards of Merit. The three other committees also met, and the Orchid Committee recommended four and the Floral Committee two Awards of Merit to novelties, but the Fruit and Vegetable Committee found nothing to do. At the 3 o'clock meeting of the Fellows Mr. Arthur W. Hill, M.A., delivered a lantern lecture on "The History and Function of Botanic Gardens."

Floral Committee.

Present: H. B. May, Esq. (in the chair), Messrs. E. H. Jenkins, W. P. Thomson, Chas. E. Pearson, Arthur Turner, Charles Dixon, W. H. Page, J. W. Moorman, C. R. Fielder, F. W. Harvey, George Gordon and John Green.

AWARDS OF MERIT.

Primula l'île de Nancy.—This is a handsome hardy garden variety, derived probably from *P. Veitchii*, which it closely resembles in habit and colour, and in the breadth, substance, lobing and variation of the leaves, which differ, however, in being much less hairy below. The flowers are borne in close umbels of about a dozen flowers on stalks six to nine inches high. In colour they are a bright magenta-rose, with a small yellow eye, and the edge of the petal is distinctly and prettily fimbriated. (Shown by Messrs. J. PIPER AND SON.)

Amygdalus persica rosea fl. pl. pendula.—A weeping form of the rose-pink Peach, shown as a tall standard. The plant will be most valued for its habit. (Shown by Mr. L. R. RUSSELL.)

Orchid Committee.

Present: De Barri Crawshaw, Esq. (in the chair), Messrs. Jas. O'Brien (hon. secretary), Gurney Wilson, W. Bolton, S. W. Flory, J. E. Shill, J. Charlesworth and T. Armstrong.

AWARDS.

AWARD OF MERIT.

Odontoglossum eximium The Dell variety (ardentissimum × crispum), from Baron BRUNO SCHROEDER, The Dell, Englefield Green (gr. Mr. J. E. Shill). A very fine flower, of perfect shape, the sepals and petals broadly margined with white tinged by the reflection of the dark purple on the back. The inner surface bears one large, irregular, claret-red blotch, with some smaller markings round it. Lip white in front, with a large red blotch and some smaller red lines; crest yellow.

Mitonia vexillaria Lyoth (vexillaria chelensis × Memoria G. D. Owen), from Messrs. CHARLESWORTH AND Co., Haywards Heath. One of the best of their fine home-raised *M. vexillaria*. Flowers large rose, with a fine purplish-crimson mask on the lip, from which radiate short lines of the same colour.

Odontioda Joan (Odontioda Charlesworthii × Odontoglossum ardentissimum), from Messrs. CHARLESWORTH. In colour near to *O. Charlesworthii*, but with a more broadly-expanded flower. Colour bright red, with yellow crest and some light-yellow markings on the lip.

Odontoglossum Elissa (Edwardii × illustrissimum). Flower of the same form as several of the *O. Edwardii* crosses, but with broader segments, purple in colour, and with yellow crest. From PANTIA RALLI, Esq., Ashtead Park.

GENERAL EXHIBITS.

Lord GRANTLEY, Red Rice, Andover, showed *Odontoglossum Zena (Sceptum × Hartyanum)*.
DE B. CRAWSHAY, Esq., Sevenoaks, showed a fine form of *Odontoglossum Crawshayanum*.

G. HAMILTON SMITH, Esq., Finchley (gr. Mr. Coningsby), showed a natural hybrid form of *Cymbidium glebelandense (Schröderi × insigne)* (syn. *C. Cooperi*).

Messrs. SANDER AND SONS, St. Albans, showed the white *Cattleya Gravesiana amabile (Mossiae Wageneri × Luddemanniana)*.

PANTIA RALLI, Esq., Ashtead Park, exhibited *Odontoglossum Pescatorei virginea*, a large form with violet-coloured blotches, and *Cattleya Luddemanniana Stanleyi*.

Messrs. CHARLESWORTH AND Co., Haywards Heath, showed a good selection of home-raised hybrid Orchids, including *Odontoglossum crispum Albania*, a seedling form of remarkable beauty; *Brasso-Cattleya Digbyano-Schröderae Bradshawiae*, a fine white flower; B.-C. Princess Elizabeth, a pretty hybrid between B.-C. Digbyano-Mendelii and *C. Mossiae*; *Angraecum fastuosum*; and the pure white *Trichopilia Backhouseana*.

Narcissus and Tulip Committee.

Present: E. A. Bowles, Esq. (in the chair); Rev. Joseph Jacob, Messrs. Wm. Poupard, W. W. Fowler, C. Lemesle Adams, H. Backhouse, P. D. Williams, W. A. Milner, G. Reuthe, P. Rudolph Barr, G. W. Leak, J. D. Pearson, Alex. M. Wilson, Arthur R. Goodwin, F. Barchard, H. V. Warrender, W. F. M. Copeland, J. T. Bennett-Poë, W. A. Watts, Herbert Smith, Charles Dawson, and Chas. H. Curtis (hon. sec.).

AWARDS OF MERIT.

Narcissus Lady Superior (show).—An exceedingly beautiful Barrii bloom which has broad, overlapping white perianth segments, and yellow corona tipped with fiery orange. (Shown by Messrs. R. H. BATH, LTD.)

N. Nightingale (show).—An early Poeticus variety of almost perfect form; the perianth segments are pure white, and the corona is flat and brilliant in colour. This and the two following varieties were shown by Messrs. CARTWRIGHT AND GOODWIN.

N. Morven (show).—A medium-sized Trumpet variety in which the white perianth forms a fitting background for a lemon-yellow trumpet, which is long and widely expanded.

N. Scarlet Gem (show).—A rather small-flowered Poetaz (*Polyanthus*) hybrid of striking appearance. The combination of clear yellow perianth and compact fiery-orange corona is very pleasing.

N. Southern Gem (garden and for cutting).—A chaste Leedsii Daffodil of large size. The white perianth segments are broad and of good substance, the trumpet-like corona is primrose-coloured when it first opens, but changes to milky-white in a few days. (Shown by Mr. HERBERT PHILLIPS.)

N. Admiration (garden).—A Poetaz (*Polyanthus*) hybrid which has rather large, soft yellow perianth segments and orange-coloured corona. (Shown by Messrs. VAN WAVEREN AND SONS.)

N. Princess Juliana (show).—A very large, rich yellow Trumpet Daffodil; the long trumpet being regularly serrated and widely expanded. (Shown by Messrs. BARR AND SONS.)

N. Golden Sceptre (show).—An unusually large Jonquilla hybrid of perfect form, rich yellow in colour and sweetly perfumed. (Shown by Messrs. DE GRAAFF BROS.)

OPEN CLASSES.

Collection of Daffodils, 48 varieties.—The three exhibits in this champion class made such an imposing display as to largely atone for the thinness and lack of attraction in some of the other classes in this division. In these splendid exhibits were arrayed rows of beautiful blooms, most of them of the highest quality, characterised by bright fresh colours, the blooms boldly set on stout stalks, compelling the admiration of the visitors. The schedule required distinct varieties fairly representative of the different divisions. As regards the first four divisions, the latter condition was liberally interpreted, and the Poeticus varieties were plentiful, but the remaining sections were very poorly represented.

The 1st prize was won by Mr. A. M. WILSON, Shovell, Bridgwater, whose collection was particularly strong in incomparabilis varieties. But his outstanding variety, and probably the "flower of the show," was an unnamed Leedsii,

which we understand will go to Holland. The very large flowers are fully 4 inches across, and the pure white perianth segments are of good substance, overlapping so as to form the desired round bloom, whilst the small, creamy corona is brightened by splashes of orange-yellow. The chief Trumpet sorts were Berseker, Countess of Stamford and Cleopatra. Of the incomparabilis blooms the most noteworthy were Lamancha, Lanceolot, Leontes, and several unnamed seedlings; whilst Cossack, Brambling, Gothelmei and Bonfire, amongst the Barrii sorts, were particularly charming; 2nd, Mr. C. BOURNE, Simpson, Bletchley, who had also many beautiful incomparabilis varieties, of which the principal were Whitewell, Duke of Leinster, Bernardino, Brilliancy and Countess. Also noteworthy were such Barrii sorts as Sunrise, Cossack and Red Lady, and the Trumpet varieties, Judge Bird, Lord Roberts, Cornelia, and Mrs. H. T. Veitch; 3rd, Mr. F. H. CHAPMAN, Rye, in whose collection Crater, an incomparabilis, in which the beauty of the yellow perianth segments is enhanced by the broad, widely-expanded rich orange corona, attracted a deal of attention. Of the standard sorts, Orangeman, Will Scarlett, Seagull and Gloria Mundi were particularly good.

Twelve Long Trumpet Daffodils.—The 1st prize exhibit of Mr. C. BOURNE was noteworthy for the purity of the varieties with white perianth segments, and of these Mrs. Robert Sydenham, White Emperor and Conqueror were splendid; 2nd, Messrs. CARTWRIGHT AND GOODWIN, whose collection included the beautiful variety Morven, which received an Award of Merit, and excellent blooms of Onslaught, Fort George and King Solomon; 3rd, Mr. W. A. WATTS, Bryn, St. Asaph.

Twelve Incomparabilis Daffodils.—Messrs. CARTWRIGHT AND GOODWIN won the 1st prize with an exquisite set of blooms, amongst which the bright corona of Marshlight was particularly prominent. Tiger, Sulphur Queen, Wonderland and Giraffe were also unusually fine; 2nd, Mr. C. BOURNE, whose outstanding variety was Macebearer; 3rd, Mr. W. A. WATTS.

Twelve Barrii Daffodils.—The competition in this class was very good indeed, and the dainty, bright-eyed blooms had a very pretty appearance. Mr. C. BOURNE, who staged Queen of Hearts, Brilliancy, Red Eye and Southern Star in exceedingly good form, won the 1st prize; 2nd, Mr. F. H. CHAPMAN, who had several beautiful unnamed seedlings.

Nine Leedsii Daffodils.—The 1st prize in this class was awarded to Messrs. CARTWRIGHT AND GOODWIN, who had good blooms of Nemesis, Thistle and Felspar; 2nd, Mr. W. A. WATTS, who showed good blooms under seedling numbers.

Nine Daffodils, Selected from Divisions I., VI., and VII.—Messrs. CARTWRIGHT AND GOODWIN, the only exhibitors, were awarded the 1st prize for an interesting collection, which included Quakeress, Araby, Buttercup, and Water Nymph.

Six Polyanthus (Tazetta) Daffodils.—In this class also Messrs. CARTWRIGHT AND GOODWIN found no competitor, and they were awarded the 2nd prize.

Six Poeticus Daffodils.—Of the three sets of blooms, the best was shown by Mr. F. H. CHAPMAN, who had excellent flowers of Ditty Ibis and four unnamed seedlings; 2nd, Mr. C. BOURNE; 3rd, Mr. W. A. WATTS.

Six Double Daffodils.—Messrs. CARTWRIGHT AND GOODWIN, the only exhibitors of Double Blooms, staged very attractive flowers of Tintoretto, Sundown and Plenipo.

SEEDLING AND NEW DAFFODILS.

Except in the first class, which allows the varieties to have been introduced into commerce since or during 1910, the following classes are for distinct varieties not yet in commerce, one stem of each to be shown:—

Twelve Daffodils.—The R.H.S. Standard Cup and 1st prize were won by Mr. C. BOURNE for a beautiful collection, from which we select Even-song (white perianth, pale primrose corona), Golden King (rich yellow Trumpet), Lullaby and Red Eye (Poeticus varieties of good shape and pure white perianth surrounding bright corona); 2nd, Mr. W. A. WATTS, whose collec-

tion of unnamed varieties contained several promising novelties; 3rd, the Duke of Rutland.

Twelve Daffodils.—Mr. P. D. WILLIAMS, Lanarth, St. Keverne, Cornwall, won the Engleheart Challenge Cup and 1st prize with varieties shown under seedling numbers. This collection contained several very good Barrii varieties, a promising Leedsii, and an excellent Trumpet bloom; 2nd, Mr. W. WELCHMAN, who showed all Trumpet varieties, Lord Cromer (rich yellow self), Clodia (white perianth and yellow trumpet) being exceedingly good; 3rd, Mr. F. H. CHAPMAN.

Six Daffodils.—Mr. A. M. WILSON, showing Abigail (lemon-yellow Trumpet) and unnamed seedlings, won the 1st prize; 2nd, Mr. H. G. HAWKER, Strode, Emington, who in Dread possesses a chaste Leedsii flower; 3rd, Mr. W. A. WATTS.

Three Daffodils.—The best seedlings were Harpagon (Barrii) and unnamed Barrii and Incomparabilis blooms; 2nd, Messrs. CARTWRIGHT AND GOODWIN, whose Crimson Queen (Barrii) promises to be valuable; 3rd, Rev. T. BUNCOMBE.

Twelve Hybrid triandrus Daffodils.—In this class Mr. W. A. WATTS won the 1st prize with a very interesting collection, shown under seedling numbers; 2nd, Mr. F. H. CHAPMAN.

The class for 6 Hybrid triandrus Daffodils attracted only one exhibitor, Mr. W. F. M. COPELAND, West View, Shirley, Southampton, who showed some interesting forms.

Twelve Seedling Daffodils.—In this and the following seedling classes the varieties shown were to have been raised by the exhibitor. The 1st prize collection, shown by Mr. A. M. WILSON, was exceedingly beautiful, and very varied. Most of the varieties were unnamed, but Anzila, a pink-flushed Leedsii, Anicet, which has an orange piceae-like edge to the corona, and Martha, a charming Barrii bloom, were admirable; 2nd, Mr. W. WELCHMAN, who showed Trumpet varieties; 3rd, Mr. W. F. M. COPELAND.

The 6 seedlings which won the 1st prize for Mr. P. D. WILLIAMS included Lysander, a Barrii bloom with a broad fiery-orange rim to the yellow corona; 2nd, Mr. F. H. CHAPMAN; 3rd, Mr. W. A. WATTS.

Mr. W. G. LOWER, showing good unnamed Barrii, Trumpet, and Poeticus varieties, won the 1st prize for 3 seedlings; 2nd, Mr. F. BATSON, Beaworthy, Devon; 3rd, Mr. C. L. ADAMS, Pendeford Hall, Wolverhampton.

SINGLE BLOOMS.

Mr. P. D. WILLIAMS, showing large, well-formed, unnamed blooms, won the 1st prizes for Trumpet (1a and 1b) Daffodils, and Messrs. CARTWRIGHT AND GOODWIN, who showed Conqueror, were similarly successful in the bicolor Trumpet class.

Martel (rich yellow), from Mr. W. B. CRANFIELD, East Lodge, Enfield Chase, was the best Incomparabilis (a), and Great Warley, from Mr. W. A. WATTS, the best (b) variety.

Unnamed blooms from Mr. A. M. WILSON, won the 1st prizes for Barrii (a and b) blooms.

Thistle, shown by Messrs. CARTWRIGHT AND GOODWIN, took first place in the class for Leedsii Daffodils. Canopy, by Mr. CRANFIELD, was the best trumpet-shaped triandrus bloom, and an unnamed seedling by Mr. P. D. WILLIAMS the best short-cupped variety.

The best Jonquilla hybrid proved to be Buttercup, shown by Mr. P. D. WILLIAMS.

Mr. A. M. WILSON, showing very fine unnamed seedlings, won the 1st prizes for Poeticus (Polyanthus) and Poeticus seedlings.

Mr. W. A. WATTS, who showed Linos, a very attractive pale yellow and orange-coloured bloom, had the best double variety.

AMATEURS' CLASSES.

Collection of Daffodils, 24 varieties, distinct.—The premier class in the amateurs' division contained only two exhibits, and of these the better was shown by N. G. LOWER, Esq., Presteign, Radnorshire, who had especially good blooms of Bernardino, Noble, Sunrise, Ethelbert, Cleopatra, Giraffe, and Madonna; 2nd, Rev. T. BUNCOMBE, The Rectory, Black Torrington, whose collection was strong in the Poeticus varieties.

Six Long Trumpet Daffodils.—There was not much to choose between the two competitors in

this class. The Rev. T. BUNCOMBE, who won the 1st prize, showed a rather wider range of colouring, whilst Mr. H. R. DARLINGTON, Park House, Potters Bar, staged especially good, rich yellow varieties. The best variety in the 1st prize set was Weardale Perfection, and Olympia was the pick of the 2nd prize exhibit.

Six Incomparabilis Daffodils.—The same exhibitors as in the previous class shared the prizes here, and the Rev. T. BUNCOMBE again won the chief award by means of a greater range of colour; his blooms of Gloria Mundi, Lucifer, and aurantius were very charming. Whitewell, as shown by Mr. DARLINGTON, was distinct and attractive.

Six Barrii Daffodils.—In this class the positions were reversed, Mr. H. R. DARLINGTON winning the 1st prize with an excellent set of blooms, the varieties Sunrise, Seagull, Branston and Circle being delightful. The best of the Rev. T. BUNCOMBE's exhibit was Stonechat.

Six Leedsii Daffodils.—The Duke of Rutland, Belvoir Castle, Grantham (gr. Mr. W. H. Divers), won the 1st prize in this class quite easily, showing superior varieties and finer flowers. Diana, Lowdham Beauty, and Marguerite Durand being exceptionally fine; 2nd, Rev. T. BUNCOMBE.

Six Poeticus Daffodils.—Nearly all the blooms in the two exhibits in this class were of very good quality. Mr. H. R. DARLINGTON, who was awarded the 1st prize, had very fine examples of Herrick, Homer, and Horace, whilst the 2nd prize set of the Rev. T. BUNCOMBE was especially rich in Lycidas and Horace.

Six Hybrid triandrus Daffodils.—Mr. H. R. DARLINGTON was the only exhibitor, and was awarded the 1st prize for typical blooms of such varieties as Queen of Spain, Zoë, and White Witch.

Six Polyanthus (Tazetta) Daffodils.—Here again Mr. DARLINGTON was uncontested, and was awarded the chief prize. His stems of Jaune à Merveille and Klondyke were first-rate.

Three Double Daffodils.—The two exhibits of these varieties were of very ordinary quality. Mr. H. R. DARLINGTON was awarded the 1st prize and the Duke of Rutland the 2nd.

The competition in the class for a collection of Daffodils, 3 stems each of 36 varieties, representing divisions 1, 2, 3, 4, 5, 9, and 10 (6 and 7 optional), open to all amateurs, was the best in the show, and brought forward many excellent blooms. The 1st prize was won by Mr. W. B. CRANFIELD, who showed a fairly representative collection, in which Royalty, Falconet, Boomerang, Seagull, Zita, and Princess May were exceptionally good; 2nd, Rev. T. BUNCOMBE, who could not have been many points behind the former; 3rd, the Duke of Rutland.

SECTION III.

The following classes were open to amateurs who did not exhibit in the previous classes:—

Mr. L. STUDDOLME, Ballyeighan, Birr, Ireland, won the 1st prize offered for 12 Daffodils, representing the different divisions, with a splendid set of blooms, in which Heroine, Argent and King Alfred were prominent; 2nd, Mr. W. F. MITCHELL, The Lodge, Leek Wootton; 3rd, Rev. Canon FOWLER, Earley Vicarage, Reading.

Mr. G. CHURCHER, Woodcote, Alverstoke, showing excellent blooms, was placed 1st for three Trumpet (a) Daffodils.

Mr. W. B. CRANFIELD won the 1st prize for three Trumpet (b) and three Incomparabilis (b).

Mr. R. MORTON, 5, Cophall Court, E.C., was the most successful exhibitor with Trumpet (c), Incomparabilis (b) and Barrii (b) blooms.

Mr. W. F. MITCHELL showed the finest Leedsii and Double Daffodils.

Miss WARREN, The Oaks, Westbere, Canterbury, won 1st prize for three Tazetta blooms, and Mr. J. CHURCHER was similarly successful with three Poeticus varieties.

Scientific Committee.

APRIL 7.—Present: Mr. E. A. Bowles, M.A. (in the chair); Sir Everard in Thurn; Messrs. Shea, Bateson, Wilson, Worsdell, Worsley, Bennet-Poë, Fraser, Hales, F. J. Chittenden (hon. sec.), and Chapman (visitor).

Abnormal Narcissi.—Mr. W. C. WORSDELL reported upon the abnormal flowers of Narcissus tridymus de Graaf, shown at the last meeting, as follows:—The three sepals were normal.

The three petals were partially transformed into stamens. In this process each petal exhibited two main parts—an outer portion, consisting of the upper part of the versatile anther, with two petaloid lateral extensions; an inner portion consisting of the corona; this latter composed of the lower lobes of the versatile anther with two petaloid lateral extensions (corona proper). In fact, just as there were clear transitions between the upper anther lobes and the ordinary petaloid lamina, so there were still clearer transitions between the basal anther lobes (in some cases upturned, in others deflexed) and the ordinary corona of the petal. These transitional structures demonstrate the homology existing between (1) the "trumpet," or corona, and (2) the upturned basal lobes of a versatile anther which has become petaloid. From which it follows that the perianth of Narcissus has been derived in the past from stamens. Celakovsky observed similar phenomena, and deduced the same conclusions in petaloid stamens of *N. tazetta*. The stamens and pistil were normal. It is interesting to note that the malformation occurred in 1913 as well as this year. It was very similar to that shown by the specimen sent to the Committee by Sir F. W. Moore last season, and to that which occurred in the garden of Mr. Polman Mooy.

Pollination in Orchards.—Mr. C. H. HOOPER sent a communication concerning this matter with suggestions of experiments and observations which have already been printed in these columns.

Narcissus hybrid.—Mr. CHAPMAN, of Rye, showed a pretty little hybrid miniature Narcissus with the corona slightly paler in tint than the perianth. He had raised it by crossing *N. calathinus* with *N. cyclamineus*, the former being the seed parent. It flowered six years from the sowing of the seed.

Fasciation.—Mr. WORSLEY showed a specimen of *Daphne odora* greatly fasciated, and Sir Daniel Morris, a fasciated Primrose.

Pelargonium hybrids.—Mr. J. FRASER contributed further remarks upon hybrid scented Pelargoniums dealing with the group of forms round *P. Unique*.

Cymbidium madidum.—Mr. BENNETT-POE showed an inflorescence of *C. madidum* (= *C. albiciflorum*), a species native in North Australia and rarely seen in cultivation.

Salix Caprea with pistillody of stamens.—Mr. FLETCHER, of Aldwick Manor, Bognor, Sussex, sent shoots of *Salix Caprea* bearing catkins in which the stamens had become converted into pistils. The example was very similar to that shown by Mr. Bowles in *Salix cinerea* at a previous meeting, and described and figured in *R.H.S. Journal*, vol. 36 (1910), pp. xxxv., xxxvii., xxxviii.

Leaf variation in Lonicera japonica.—Mr. CHITTENDEN showed a specimen of *Lonicera japonica* with strong young shoots on which the foliage was rather deeply lobed instead of being entire, as in the normal form. Similar changes in form of foliage are frequent in *Symphoricarpos racemosus* in certain stages of growth.

HORTICULTURAL CLUB. THE FLORA OF NIGERIA.

APRIL 7.—The monthly dinner of the Horticultural Club was held at the Hotel Windsor, on the above date, when Mr. W. A. Bilney presided over a gathering which included Miss Amaury, Mr. and Mrs. P. Amaury Talbot, Miss Willmott, Dr. and Mrs. Fraser, Captain and Mrs. Villiers Stuart, Dr. Shillitoe, Mr. and Mrs. H. R. Darlington, Messrs. E. A. Bunyard, W. Cuthbertson, C. H. Curtis, C. T. Drury, R. Hooper Pearson, W. T. Ware, and A. Worsley.

Mr. P. Amaury Talbot, who has been District Commissioner for the Oban and the Eket Districts of Nigeria, delivered a lecture on the Flora of that colony. By the aid of excellent lantern-slides and many water-colour drawings from the brush of Mrs. Talbot, the lecturer conveyed realistic impressions of the wonderful vegetation of the tropics and the habits and superstitions of the natives. Mr. Talbot is known to science as a painstaking anthropologist, but to the general reader he is best known as the author of "In the Shadow of the

Bush," a work of consuming interest in which he records the habits and folklore of the natives of Nigeria, especially dealing with the blood-stained "Juju and Fetish Worship." Although this book is written primarily from the standpoint of the anthropologist, it contains much of interest to the horticulturist. The general views of the country, including its rivers and waterfalls, of giant lianes which crush the life from their supports, and the intensely interesting cauliflorous trees, cannot fail to interest the garden-lover. In introducing his subject at the Horticultural Club, Mr. Amaury Talbot remarked that whilst he intended to make special reference to some of the 250 new genera and species which he had been fortunate enough to discover, he did not propose to give a technical enumeration of these new flowers—such details will be published by the Natural History Museum authorities. The scope of the lecture was to give a general idea of the Nigerian vegetation, and of the point of view from which the natives regard the vegetable kingdom; "animated for them by spirits—either beneficent or malignant—varying in power from the dryads of the great trees to the 'Mana' of each little flower." In many villages the great trees are looked upon as being the guardian spirits of the compound and mighty to protect its inhabitants from enemies. These primitive people often believe that great trees, such as the giant silk-cotton trees, which tower to a height of 200 or more feet, their clean straight trunks crowned with luxuriant verdure, always give signs to those who believe in them.

Commencing with the Gulf of Guinea, where the coastal lands consist of Mangrove marsh, which he described as "only land in the making," the lecturer described the Palm stretches, where these trees wave their branches high above the under vegetation. Then followed what is usually termed the evergreen belt, but a more critical investigation showed that this district contains a large number of deciduous trees, which renew their growth and flower twice, and in some instance, as many as four times, a year. Beyond to the north lies the grass lands, which support grasses 15 to 16 feet high, and which further northwards give place to the vast arid Sahara desert.

Reference was made to the dangers of the forest attendant on trips to the interior—from dead trees, which collapse at unexpected moments, and falling fruits, solid and heavy, as large as cannon balls, which give no warning. The frail bridges of bamboo, or merely a tree trunk, thrown across the deep creeks of icy-cold water, quickly decay in the humid climate and "crave wary walking." These dangers, as well as the pleasure and excitement of discovering new species, were shared by Mrs. Talbot and her sister, Miss Amaury, both of whom assisted greatly in collecting the botanical specimens—an arduous task in the all-pervading moisture, which necessitated fires for drying the specimens.

NEW PLANTS.

Of the discoveries described and illustrated, the most interesting were the cauliflorous trees—trees which, as sometimes does the Judas tree (*Cercis Siliquastrum*) in this country and an occasional Apple or Pear tree, produce flowers on the mature trunks. The reason for this divergence from the normal method yet awaits explanation, for species which flowered in the ordinary way in Obau were cauliflorous in the marsh lands of Eket. In the latter district these "bark-flowering trees, so rare in other quarters of the globe, exist in such countless numbers and varieties" as to form an attractive problem. Dr. Otto Stapf suggests that a solution may be found by studying the slugs of the neighbourhood, which probably fertilise the flowers. The humidity caused by the excessive rainfall, which averages 175 inches, may also be a contributory cause.

Most wonderful of these trees is a new Anacardiaceae, whose "branchless trunk shoots up for a hundred feet or more, all but covered by bunches of flowers, often a foot to a foot and a-half in length, and much the shape of our own Lilac trusses, but vivid red in colour. The fruit of this wonderful tree is, however, the most striking sight of all: for the clusters hang from the trunk like colossal Grape-bunches formed of scarlet Plums, the juice of which, delicious though sharp in taste, is the colour of red ink."

Many new species of *Napoleona* were found, and of these *N. Egertonii*, which, instead of the normal solitary flowers, has a paniculate inflorescence, *N. Alexandri*, *N. parviflora*, *N. megacarpa*, *N. Gascoignei*, which produces its flowers in clusters of 10 to 30, *N. rhodantha*, distinct in that the staminal whorl is pink instead of white, and the second whorl is edged with oval spots of white set in crimson, are the names of a few.

Paintings of many new *Rubiaceae* were also on view, and of these *Randia Galtonii*, which has a flower-tube 8 in. long, and *Gardenia physophylla*, with flowers so long in the tube that they may well pass for blooms of a *Datura* (*Brugmansia*), are typical. *Strophanthus Cunliffei* was shown, bearing sprays of beautiful, pink-flushed flowers; it is from this plant that a most deadly poison, used for tipping arrows, is obtained. A new *Vanilla* (*V. nigerica*) is of decided garden value. *Urania obanensis*, *Markhamia lutea*, *Cola gigas*, orange-like fruits of *Landolphia stipulosa*, and *Spathodea campanulata*, were also illustrated in colours.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 26.—*Committee present*: Z. A. Ward, Esq. (in the chair), Messrs. J. Bamber, J. Cypher, A. G. Ellwood, J. Evans, A. Hamner, W. H. Hatcher, J. Howes, J. Lupton, D. McLeod, W. J. Morgan, C. Parker, W. Shackleton, H. Thorp, G. Weatherby, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Cymbidium Pauwelsii maxima, from J. LEE-MAN, Esq.

Brasso-Cattleya Vilmoriniana var. *Centaur* (*B.-C. Leemaniae* × *C. Mossiae*), from W. R. LEE, Esq.

Odontoglossum × *Princess of Pless*, a large flower of brilliant colour, and evenly marked, from R. LE DOUX, Esq.

Odontoglossum Brewii "Walton Grange" variety, from WM. THOMPSON, Esq.

Cattleya Warneri "Ardenholme," from Colonel J. RUTHERFORD, M.P.

AWARDS OF MERIT.

Cymbidium Pauwelsii, *C. delicata*, and *C. Andreana*; *Cattleya Enid excelsa*, *Brasso-Cattleya Veitchii* "Leeman's" variety, all from J. LEE-MAN, Esq.

Odontoglossum ardentissimum Phoebe and *Dendrobium nobile Goliath*, from WM. THOMPSON, Esq.

Odontoglossum × *Niger* and *Odontoglossum crispum White Swan*, from R. LE DOUX, Esq.

Odontoglossum Jasper "Beardwood," *Brasso-Cattleya beardwoodense* (*Empress Frederick* × *Digbyana*), from Col. J. RUTHERFORD.

Lycaste gigantea Ashlands variety, from R. ASHWORTH, Esq.

Dendrobium superbum Rochelenii giganteum, from Messrs. MANSELL AND HATCHER, Rawdon.

Brasso-Cattleya Pocahontas Undine (*B. Digbyana* × *C. Eldorado alba*), from Messrs. CYPHER AND SONS.

NURSERYMEN, MARKET GARDENERS, AND GENERAL HAILSTORM INSURANCE CORPORATION.

APRIL 3.—The nineteenth annual meeting of this company was held at 41 and 42, King Street, Covent Garden, on the 3rd inst. Sir Harry J. Veitch, who presided, congratulated the shareholders on the continued growth and success of the corporation and the strength to which it had attained. The company had during the past year increased the allowance to policyholders from 15 to 25 per cent. The Reserve Fund amounted to more than twice the paid-up capital. Five claims had been received during the year.

The usual dividend of 1s. 6d. and bonus of 6d. per share were declared, and a further sum of £1,000 was added to the Reserve Fund.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

APRIL 6.—The monthly committee meeting of this society was held in the R.H.S. Hall on the 6th inst., Mr. Chas. H. Curtis occupying the

chair. Four new members were elected. Seven members were allowed to withdraw double the amount of interest, amounting to £23 18s. 4d., one member over the age of seventy years withdrew from his deposit account the sum of £20, one lapsed member over sixty years was allowed to withdraw his deposit, viz., £32 6s. 10d., and one member over the age of seventy years was allowed 5s. per week for life from the Distress Fund. The sick pay for the month on the ordinary side amounted to £38 10s. 6d., and on the State side £36 3s.; whilst £10 10s. was paid for maternity benefits.

DEBATING SOCIETIES.

DERBYSHIRE GARDENERS.—At the meeting of this association, held on the 20th ult., an address on "The Use of Phosphatic and Potassic Manures in Gardening" was delivered by Mr. W. Goodwin, Principal of Kingston College. Mr. Martin presided. The lecturer stated that the effect of nitrogen was an increase in leaf development, and it tended to produce abnormal growth to the disadvantage of the productiveness of fruit, roots or flowers. To counterbalance that state of things something was necessary to push in opposition and keep the nitrogen in check, to stimulate and promote the reproductive organs, and make the tree fulfil its normal functions, and this phosphate would do. Phosphate, said Mr. Goodwin, was obtained from several sources, but originally it was supplied only from bones dissolved in sulphuric acid. The acid destroyed the lime in the soil, so that a lack of lime was always a disadvantage, and that point should be safeguarded, otherwise there was a risk of "finger and toe" and fungoid diseases appearing in the crops. A medium dressing was 1lb. to 10 square yards. Another form of phosphate was steamed bone-flour, which was largely used for potting purposes, and it might be employed with advantage on sandy soils in conjunction with farmyard manure. It necessitated intelligent observation by the individual himself, for much depended on the physical condition of the soil and the quality of the natural manure; any leakage at the manure heap was a loss of phosphate. Another phosphatic manure, basic slag, contained lime, but no acid, was slow in action, therefore lasting, and suitable for wet, cold, clayey land. It then gave up its phosphate quicker on account of the watery nature of the soil, hence it might be determined that its effect would be extremely slow on a dry, sandy land, but under ordinary conditions the effect of basic slag would last six or eight years. The specific use of potash was concerned in the production of sugar and starch in the plant, which was an important point. Kainit contained 12 per cent. of potash. It was slow in action, but satisfactory results would be obtained if applied to the land in the autumn in conjunction with basic slag. Sulphate of potash contained double the quantity of available potash, and was often used in conjunction with superphosphate.

BIRMINGHAM AND DISTRICT GARDENERS.—At the meeting of this society, held on the 23rd ult., the prizes were presented for the essays written by junior members, on *Begonia Gloire de Lorraine*. A lecture was delivered by Mr. A. D. Christie on "Success and Failure in Growing Vegetables in Towns." Mr. Christie gave his experience as a grower both in this country and in Russia.

—At the meeting held on the 9th ult., Mr. J. Palmer, Chad Valley Nurseries, Edgbaston, read a paper on "The Best Varieties of Sweet Peas and Antirrhiums." A review of the big shows, he said, provided ample proof that Sweet Peas are not declining in popularity, but splendid as many of these varieties are today, there is still room for development in their colours. A second paper, entitled "Salvia splendens for Summer Bedding," was given by Mr. S. Smith, Handsworth. A new idea, unadvocated hitherto, was the growing of *Salvias* in tubs, the rapid growth and free flowering of this plant rendering it specially adaptable for this purpose.

READING GARDENERS.—At the meeting of this association held on the 2nd ult., Mr. W. F. Giles, of Messrs. Sutton and Sons, gave a lantern lecture on "Vegetables for Home and Exhibition, with Notes on Staging." He described the chief points to be observed in exhibiting single dishes or collections, how to group the subjects and on what background, how to build them up and fix them securely against accidents.

—There was a large attendance at the meeting held on the 16th ult. Mr. J. T. Tubb (chairman of the committee), presiding. The lecturer for the evening was Mr. J. W. Barks (a member of the Redhill and Reigate Society), and his subject was "Vines and Peaches." Mr. Barks, in his paper on the vine, said that his methods, which were greatly criticised by his neighbours at the time, were based on the fact that he was expected to produce Grapes in as short a time as was compatible with securing crops in subsequent years. Hence, when he planted his canes, they were not shortened as usual, the object being to have as much of the training space as possible filled in the first season, besides securing one or two bunches of fruit. By carefully stopping vigorous shoots and allowing weaker ones to grow, he successfully established lateral shoots on either side of his newly planted canes in the first season. He was careful to explain that he avoided overcropping for the first year or two after planting, and did not force the vines in the early stages of growth. The originality of his treatment was justified by the results and the description of his methods was closely followed. In the remaining

portion of his paper—on the Peach—Mr. Barks gave details of his treatment in the crucial stages of the forcing of the fruit.

KILMARNOCK AND DISTRICT GARDENERS'.—At the monthly meeting held on the 11th ult., presided over by Mr. R. K. Sillars, Mr. Thos. Limond, Lecturer on Agriculture for the county of Ayr, delivered an address entitled "Modern Ideas about Manuring." Mr. Limond described how our knowledge and use of manures had increased from the time when the term "manuring" was merely used to indicate hand tillage of the soil, to the present when it denotes the use of any substance which enhances the fertility or cropping capacity of soils. One may apply fertilisers regularly and in abundance, but unless the physical condition of the soil is correct, good results cannot be expected. The lecturer recommended the use of a moderate dressing of dung supplemented with suitable artificial fertilisers.

GARDENING APPOINTMENTS

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

Mr. W. E. Hyde, for the past 3 years Gardener to H. F. HOLLINS, Esq., Mainstone Court, Ledbury, and previously for 3 years at Norwood Hall, Sheffield, as Gardener to Admiral Sir F. INGLEFIELD, Mickleover Manor, Derbyshire. [Thanks for 1s. 6d. for R.G.O.F. box.—EDS.]

Mr. G. W. Songhurst, for the past year General Foreman at Killarney House Gardens, Killarney, Ireland, as Gardener to F. PEREGRINE BIRCH, Esq., Massbrook House, Lahardane, Crossmolina, Co. Mayo, Ireland.

Mr. W. Ansell, for the past 4½ years Gardener to the late J. W. FIELD, Esq., Southsea House, Dorking, as Gardener to W. M. DEAN, Esq., Greenways, Sunningdale, Berkshire.

Mr. G. W. Chapman, for the past 6 years Gardener to Sir JAMES WOODHOUSE, Stratton Chase, Chalfont St. Giles, Bucks, as Gardener and Bailiff to C. J. WHITTINGTON, Esq., Sandhills, Betchworth, Surrey.

LAW NOTE.

"ENGLISH" TOMATOS.

A FIRM of fruiterers carrying on business in Chelsea was summoned by the Board of Agriculture under the Merchandise Marks Act for applying a false trade description, to wit "English" Tomatos, to goods exposed for sale.

Evidence was given to show that the Tomatos came from the Canaries, and it was urged by the prosecution that cases of this kind are numerous. The defendant, who pleaded guilty, observed that during the quarter of a century that he had carried on his business no suggestion of improper trading had been made against him. He told the inspector who asked whether the fruit was English that it came from Tenerife and maintained that there could be no real deception since no one could expect Tomatos at this season at 6d. per pound.

A fine of £10 and £12 12s. costs were imposed.

Obituary.

JOSEPH BLACK.—This able cultivator of Chrysanthemums died at his home, Maxwelltown, Dumfries, on April 7th, after a long illness. A compositor by calling, Mr. Black was for many years incapable of following his avocation, and devoted himself to his flowers. His collection of border Chrysanthemums was one of the finest in Scotland, and it was wonderful how admirably they were cultivated, seeing that their owner was suffering from chronic illness.

WILLIAM DAWKINS.—From *Horticulture* we learn that a gardener of English extraction, William Dawkins, has died in Boston, Mass., at the age of 76. Mr. Dawkins was born in Tottenham, and went to Canada as a private in a foot regiment. On leaving the Army he entered the florist's business, but eventually became the assistant of Mr. Jackson Dawson in the Arnold Arboretum, where he was employed for over 21 years.

A. W. HAYTER.—The death took place at Horton, near Wimborne, Dorset, on the 5th inst., in his seventy-eighth year, of Mr. A. W. Hayter, who was for twenty years gardener to

the late Earl of Shaftesbury at St. Giles, and later for ten years gardener to Lady Henry Somerset at The Priory, Reigate. Mr. Hayter was a striking personality and a capable all-round gardener. The funeral took place in the cemetery at St. Giles on the 10th inst.

DR. JACQUES HUBER.—We learn with regret of the death of Dr. Jacques Huber, Director of the Museum Goeldi, Belem do Para, Brazil. Dr. Huber died on February 18, after a brief illness.

EDWARD MEEHAN.—The *Florists' Exchange* gives the news of the death of Mr. Edward Meehan, a well-known American nurseryman who was born in the Isle of Wight, but spent the greater part of his life in Philadelphia. Mr. Meehan was first employed in the nursery of the late Robert Buist, at Philadelphia, but later he became the manager of his brother's large nursery business at Germantown, Pa. He died on March 18, in his 79th year, leaving a widow and three sons.

BREWER OSBORN.—The news of the death, on the 12th inst., of Mr. Brewer Osborn, gardener at Holme Park, Sonning, from 1870 to 1898, will be learned with general regret. Mr. Osborn was a skilful gardener, as his exhibits at the shows of the Reading Horticultural Society testified, for he won many prizes. He was one of the original members of the Reading and District Gardeners' Society. When the Holme Park estate changed ownership in 1898, Mr. Osborn entered into business as a fruit and poultry farmer at Orchard House, Shinfield, where he passed away after a long and painful illness at the age of 71. Deceased leaves a widow, one son (Mr. A. Osborn, foreman of the Arboretum Department, Kew Gardens), and one daughter.

CANNAS: Novice, Darwin. Cannas would grow quite well in your greenhouse. The roots, if small, should be started in 4 or 6-inch pots, using a compost consisting of good loam, leaf-mould, a little manure from a spent Mushroom-bed, or thoroughly-decayed farmyard manure, with enough sand to keep the whole porous. The roots may be potted up at any time during March or April. Afford water sparingly, for an excess of moisture at the start may cause the plants to rot off. Thus they should be kept fairly dry until they have made some growth, but when numerous roots have formed and the leaves are growing freely Cannas require plenty of water at the root. The foliage should be syringed or sponged frequently, as the leaves are very liable to infestations of red spider. When growing freely the plants may be fed twice a week with diluted liquid manure or soot water. Large specimens may be shifted into 8 or 10-inch pots, but plants in 7-inch pots should be sufficiently large for a small greenhouse. In the autumn the root-stocks should be dried off gradually, and, when the foliage has completely died down, they should be stored for the winter in a dry position where frost cannot reach them.

HOLLY HEDGE FAILING: Giglamps. From your description we suspect that the cause of your Holly hedge going wrong in places is due to improper root action. The soil is most probably too dry in summer. Ascertain the condition of the roots; if they are found to be in good order replace some of the old soil with fresh compost containing a liberal quantity of manure. If the roots are unhealthy and decayed grub up the plants and replace them. An old hedge sometimes fails in places through the weaker plants being killed by their stronger neighbours.

MARÉCHAL NIEL WITH SPOTTED FLOWERS: J. D. J. The spots on the blooms may be due to canker or to the roots having grown in an ungenial sub-soil. Feed the plant once a week with liquid manure made from cow dung and soot, alternating this with dissolved blood manure. In order to allow of the liquid penetrating to the roots make three

or four holes in their vicinity with a small iron crowbar. Should canker be present, which shows itself in a warty-like growth, soil could be heaped up over the affected part provided the latter is near to the surface, but if it is at the junction of stock and scion make an incision with a sharp penknife down the stem of the tree.

NAMES OF PLANTS: S. W. B. Rhododendron; probably R. Edgeworthii.—**W. B. C.** Tussilago Petasites (Butter Coltsfoot).—*Constant Reader.* 1, Lonicera fragrantissima; 2, Abutilon Savitzi; 3, Pteris serrulata; 4, Adiantum formosum; 5, Pteris cretica albolineata; 6, Abelia triflora.—*Victor.* 1, Oncidium flexuosum; 2, Ondontoglossum blandum; 3, Masdevallia Estradae; 4, Oncidium pubes.—*J. S., Wrexham.* Cyclamen latifolium, a native of Greece and Asia Minor.

NARCISSEUS: M. P. The abnormal flower of Narcissus has the corona split up, each perianth lobe having a two-lobed portion thereof; also, in the case of one or two of these split portions of the corona, the transition in structure between them and the basal lobes of a versatile anther is obvious.

PALM UNHEALTHY: W. G. S. The portion of the Palm-leaf contains no sign of disease due to fungous or insect pests, but the plant is in a very unsatisfactory condition, pointing to wrong cultural treatment. Turn the roots out of the pot and see if the drainage is in proper order.

PEACH SHOOTS: B. W. B. We can find no trace of disease in the specimens you send us, but the wood is not properly ripened, and such shoots are best removed from the trees in the autumn, for they cannot be expected to fruit satisfactorily.

PINE BRANCHES: N. M. The shoots themselves are not diseased, but there is every indication that disease exists at the roots. Your best plan will be to assist the trees as much as possible in developing healthy rootlets by forking the soil lightly and applying a layer of animal manure as a mulch.

TOMATOS: S. J. The trouble is due to canker; a notifiable disease under the regulations of the Board of Agriculture and Fisheries. Remove all the diseased plants and burn them, also take away the soil in which they have been growing and soak the house thoroughly with a solution of sulphate of potash at a strength of one ounce in each gallon of water. It would be better not to grow Tomatos in the same house again this season, but if circumstances compel you to do so obtain fresh compost and water the plants at intervals with the specific recommended.

VINE LEAVES: D. G. P. The very dark colour of such leaves as have expanded, and the glutinous exudation on them, point to an excessive supply of nitrogenous matter to the roots. The mischief was probably done before the present season. There is no hope of the vines ever recovering.

VINES: S. J. The leaves and shoots have been damaged by some external cause, such as scalding. Your letter seems to point to something wrong in the roof-glass at the spot where the vines are injured, seeing that two laterals only are affected whilst the others on the same plant are perfectly healthy.

WINTER-FLOWERING BEGONIAS: W. Brown. There are numbers of winter-flowering Begonias other than B. Gloire de Lorraine which you might cultivate in an intermediate house, including B. manicata, B. fuchsoides, B. Haageana, B. Gloire of Cincinnati, B. Gloire de Sceaux, B. acuminata and B. semperflorens. Many pretty garden-raised varieties of B. semperflorens are of great value for decorative purposes during the winter, and especially Gloire de Châtelaine, which has rose-coloured flowers and blooms in profusion nearly all the year round.

THE MANURING OF VEGETABLES AND FLOWERS.*

TO those who know the excellent results achieved by French horticulturists, the pronouncement of the author that his compatriots in the horticultural world are chary in the use of artificial manures will come with surprise. Yet such is apparently the case, and the purpose of this work is to convert French gardeners from indifference to a proper belief in the use of artificial fertilisers.

If sound argument and the evidence of prolonged and careful experiment can effect this conversion, M. Dumont will undoubtedly succeed.

* *La Fumure raisonnée des Légumes et des cultures maraichères.* By R. Dumont. Published by Larousse. Paris. 3 francs.

The standpoint adopted by the author is expressed with directness and lucidity in the opening chapter.—The staple manure for horticultural purposes is humus, and hence the application of dung or some other source of humus must form the basis of every rational system of manuring. The functions of artificial manures are to supply special and necessary plant foods; the mineral salts which, though present in insufficient quantities in humus, are essential for the nutrition of all plants.

M. Dumont reminds his readers that the philosophy of manuring has passed through three main phases. In the early part of last century the humus theory prevailed. That theory maintained that humus is the food of plants. Liebig in 1840 shattered the humus theory and replaced it by the "mineral" theory, teaching that plants feed on the inorganic salts—nitrates, phosphates, potash salts, etc.—which are contained in the soil solution. The shattered theory gathered itself together again, and, effecting a compromise with its rival, gave rise to the "organic-mineral" theory, which is held at the present day. As summarised by the distinguished French agriculturist Grandeau, this theory holds that humus is essential for perfect and rapid plant growth, since it makes the ideal environment for the roots. It not only helps to bring the necessary salts into solution and helps to hold them in the soil at the disposal of the plant, but it also serves the no less important function of holding water and absorbing heat. Without humus a clay is sour and a sandy soil is a loose powder. Wherefore the wise gardener digs dung into his ground and adds with the natural manure such mineral substances as his soil lacks and his plants require. Once it is admitted that the rôle of artificials is to supplement, not to replace, farmyard manure, the way is open to an intelligent and economical use of both.

Such a use must be based on a knowledge, which need be by no means profound, though it must be sound, of four sets of facts, namely, those concerning (1) the several amounts of the essential minerals which are contained in a given soil, (2) the average chemical composition of dung, (3) the requirements with respect to mineral substances of different kinds of cultivated plants, (4) the general properties and relative prices of the chief artificial manures. Such knowledge is well within the grasp of every gardener; books such as the excellent treatise under review provide information with respect to (2), (3), and (4), and simple experimentation suffices to determine the chemical composition of the soil. For this purpose direct soil-analyses, although of great value if carried out properly, are not absolutely necessary; plants themselves may be used to make the analysis, and by observing the behaviour in the garden of plants known to be exacting with respect to a given inorganic food-substance, potash or phosphoric acid or nitrogen salt, the deficiency of the soil may be inferred. As the great pioneer of plant physiology, Boussingault, observed,

"I prefer the opinion of the plant to that of ten professors."

The scope of M. Dumont's volume may be indicated in outline. After the general introduction to which we have given such prominence he describes the qualities and defects of the several types of soil—sandy, calcareous, clayey, and humus—and demonstrates by simple methods the relative powers of these soils to hold water, showing that for 100 parts of each soil, humus retains 190 parts of water, clay about half as much, chalk not much more than a third, and sand as little as from one-seventh to one-eighth. After pointing out the enormous capacity for cultivation of the wide stretches of neglected peat soils and showing what may be done by draining, liming, and supplying phosphates (as basic slag), M. Dumont deals with the liming of the soil. He takes as a standard that the lime content of light soils should be not less than 2 per cent., of medium loams 3 to 4 per cent., and of clays and peaty soils 5 to 6 per cent.

Examining next the general chemical composition of the soil, the author defines as a fairly rich soil one which contains of nitrogen 1 part in 1,000 of the natural soil, of phosphoric acid also 1 part, and of potash 2.5 parts, and insists also that these figures give not only the minimum amounts, but also the proper relations which should subsist between these mineral soil constituents. Examples of the chemical composition of special soils are given and from the composition their manurial requirements are indicated. Then follows a consideration of the perfect soil from the point of view of vegetable cultivation. It should consist of:

- Sand, 500-650 per 1,000 parts.
- Clay, 200-250 per 1,000 parts.
- Lime, 50-150 per 1,000 parts.
- Humus, 50-150 per 1,000 parts.

Such a soil would be easily worked, warm, well aerated, a good bed for nitrification, and capable of holding well the manure supplied to it.

Chapter 3 gives an account of the principal manures and their composition, and makes the most important point that the composition of the dung of the chief farm animals varies enormously, according to the kind which supplies it. After enumerating the chief artificials, their specific actions are considered, the rules to be followed in their application and the artificials which may and may not be mixed with one another. For example, dung or other organic manure must not be mixed with lime, nor basic slag with sulphate of ammonia, for in either case chemical interaction takes place and loss ensues.

The concluding sections of the work give in detail the manures appropriate to leaf, stem and fruit vegetables of the garden. We cannot but add that this admirable book deserves well the honour accorded to it—that of the Agricultural Prize given by the Society of French Agriculturists for the best contribution on "The Use of Manures in Horticulture."

ORCHID NOTES AND CLEANINGS.

COMMERCIAL ORCHID GROWING.*

The main object of this handy little volume is to demonstrate the methods by which certain classes of Orchid may be grown profitably for supplying cut flowers for market purposes, and to indicate suitable species and hybrids that may be acquired at a reasonable cost.

The cultivation of Orchids for cut flowers is a branch of floriculture which has been proved to be profitable, and the fact that the supply, especially in winter and spring, is seldom equal to the demand proves that Orchid culture for market purposes might well be added to many florists' nurseries at present growing commoner and less remunerative subjects.

For these persons and amateurs who would like to enjoy the pleasures of Orchid growing and get some return for their expenses Mr. Harrison's little treatise will be a great help.

The careful instructions on cultural points also make it a desirable guide for the beginner in Orchid culture, although he may only require flowers for his own purposes.

EULOPHIA SAUNDERSIANA.

A FINE inflorescence of a form of this African species is sent us by the Hon. N. Charles Rothschild. It belongs to the small evergreen section which is represented by *E. pulchra*, *E. macrostachya* and *E. megistophylla*, the botanical differences in which are not very well defined. *E. Saundersiana* is figured indifferently, especially as to colour, in *Xenia* II. Mr. Rothschild's plant was collected in Uganda. The scape is 3 feet long and the upper third bears 27 flowers each $1\frac{1}{4}$ inch wide. The sepals are lanceolate, the odd one erect and the laterals extended at right angles level with the column. The petals are broader and shorter, both yellowish-green, striped with purple. The lip is trilobed, the middle lobe divided in front, whitish, the side lobes striped with purple and the mid-lobe having a few purple lines. The column is green with a purple line round the margin and at the back; spur short, obtuse.

THE ROSARY.

"LES AMIS DES ROSES."

Les Amis des Roses is the title of the journal of the French Society of Rosarians, a periodical that has recently completed the eighteenth year of its publication. The journal appears every two months, and that for the year just completed forms an imposing volume of some 500 pages. It is nicely got up and clearly printed, with numerous illustrations of Roses and Rose gardens.

It is interesting to note that the French Society of Rosarians appears, like our own English Rose Society, to have discovered that there is no more efficient manner of increasing the number of its members than by continuously adding to and improving its publications. The Society may be heartily congratulated both on its increasing membership and the advance it is effecting in its literature under the editorship of the secretary, M. Albert Boutin.

The number contains, among other articles, a notice of a curious modification of the Rose *Veilchenblau*, which, it is suggested, may be due to the production of a graft hybrid. Another interesting article deals with the perfume of Roses. The author laments the decadence of many modern Roses in this respect, and suggests that in hybridisation perfume is more difficult to fix than is colour; he instances the case of the Pernetiana Roses, which have not preserved the disagreeable odour of *Rose lutea*. This is undoubtedly a subject well worthy of further attention.

* *Commercial Orchid Growing*, by C. Alwyn Harrison (Lockwood Press.) 2s.

NEW DAFFODILS.

THE illustrations in figs. 123, 124 and 125 may be regarded as mementoes of the R.H.S. Daffodil Shows of 1914, for they represent some of the most interesting novelties shown this season, while several of them have received

obtained when well grown, but the perianth was of particularly good substance, and pure white; it will be seen from the picture that it is very rounded.

Crater was shown by Mr. Herbert Chapman, and seems very happily named. The flower is of the Sunflower type with a yellow perianth, its special feature being the corona or cup, which

FIG. 123.—NARCISSUS CROESUS: CORONA ORANGE-YELLOW; PERIANTH PALE YELLOW.
(R.H.S. Award of Merit, April 7, 1914.)

the recognition of the Narcissus Committee in the shape of an Award of Merit. The large flower at the top of fig. 124 is a flower of the Leedsii section shown without a name by Mr. A. M. Wilson. It was some 4 inches across, which is large for a flower of this type, though not larger than *White Lady* may often be

is rather flat and very widely expanded. It is a very distinct flower and certain to attract attention.

Morven is a medium-sized trumpet-shaped flower with a long trumpet of lemon-yellow colour widely expanded at the mouth, and a white perianth. Perhaps the special feature of

FIG 124 NEW DAFFODILS FROM THE R.H.S. SHOW

1, UNNAMED SEEDLING OF LEEDSII SECTION; 2, CRAIER; 3, MORVEN; 4, SCABLE GEM; 5, GOLDEN SCEPTRE.
See page 278

the flower was the pleasing and cool effect produced by the contrast of colour between trumpet and perianth. It received an Award of Merit.

Scarlet Gem is one of the Poetaz section, the flowers are of moderate size, but very striking owing to the combination of brilliant orange colour in the cup with the clear yellow of the perianth. Most of these Poetaz varieties are turning out to be excellent garden flowers, but this variety was given an Award of Merit in the show section. Golden Sceptre was shown by the firm of de Graaff. It was given an Award of Merit in the show section, and is noticeable for its rich yellow colour and sweet perfume. It is a Jonquil hybrid.

FIG. 125.—NARCISSUS WHITE MAXIMUS.
(R.H.S. Award of Merit, April 7, 1914.)

There are two other flowers illustrated in figs. 123 and 125 which were exhibited at the earlier show held on April 7. Croesus (see fig. 123) is a very fine flower, and it was shown well at both exhibitions. It is a giant *Incomparabilis* raised by Mr. Henry Backhouse; its characteristics are a large, rounded imbricated primrose-coloured perianth, and a widely expanded crown rather of the Whitewell type, but of deep red colour. White Maximus (fig. 125) is a lemon or cream-coloured form of the well-known *N. Maximus* of our gardens, and similar to that variety in its fine, crinkled cup.

The above are some of the best novelties exhibited this season, but it is hoped that the Birmingham Show, which takes place on the 23rd inst., will reveal others of equal or surpassing interest.

THE VINERY.

PLANTING A NEW VINERY.

WHEN planting a new vinery it is not to be expected that the vines will furnish the space until after a few seasons have elapsed, but supernumerary vines may be set between the permanent ones, and this method is to be especially recommended where the border is inside the house. There are several advantages in growing these extra canes, but their chief value is to furnish a supply of Grapes without allowing the permanent vines to be cropped early or so heavily for a season or two as the grower might be tempted to do otherwise. When vines

made on the north side until the two borders meet. I practised this system in growing vines for ten years and no harm was done to the main rods, but we obtained a heavy crop of fruit annually within two years of planting. At Aldenhām House Gardens the system has been practised during the past few years with the greatest success, especially in vineries of Muscat of Alexandria. The temporary vines need a different treatment to the others, for instead of cutting them down to two eyes at the base, the rod is left sufficiently long to allow three buds beyond the first wire. These three buds will furnish a pair of side shoots and a leader. Remove any Grapes that form for the first year and encourage the vines to grow freely by syringing them in the afternoon, closing the house when it is well warmed with the sun's heat. At the time of pruning the following year the leader may be allowed to carry 2 feet, or, if strong, 3 feet of new wood, and from this and the side shoots already formed half a dozen bunches will be obtained the second season. In a few seasons the vines will reach to the top of the house, and the rod can then be trained down the back wall; spurs should not be permitted after the top of the roof is reached. As the permanent vines require more space the lower spurs of the supernumeraries may be cut away. If the vinery is not planted with Muscat of Alexandria, the most suitable varieties to interplant are Black Hamburgh and Foster's Seedlings for an early crop, and Madresfield Court, Black Alicante, Black Hamburgh and Lady Downes for a late supply. *E. Molyneux.*

FOREIGN CORRESPONDENCE.

NOTES FROM SOUTHERN ITALY.

WE have had a very warm February here in Naples—during the day the weather was almost hot, though the nights were cool. The first spring flowers are developing well, especially the Oriental Juno Irises and the Crocuses. The Irises have flowered splendidly. Our *Iris alata* and the varieties *alba* and *marginata* were in flower continuously from Christmas until the end of February. The greenish *Iris palestina* is better this year than usual, but it is not a striking flower, nor of much interest to any but collectors. *Iris Bolleana*, whitish-green with dark, purplish-brown patches on the falls, is very handsome, and I hope to gather a good harvest of seed from its flowers crossed with other species. *I. Heldreichii* and *I. Tauri* have done well, and I have two fine hybrids from a cross between these species. *I. Mme. Müller* (*Heldreichii* × *Tauri*) resembles *Heldreichii* in form and *Tauri* in colour. The falls are 2½ inches long, of a purple-violet colour; the large blade is blackish-purple, and around the yellow crest are white stripes. The standards are an inch long and broad at the ends; the styles are as long as the falls, and reflexed. The plant grows quickly, and is very floriferous. I have had as many as four blossoms from a single bulb. The cross was effected in the spring of 1908, but the hybrid has not flowered until this year.

Iris Mme. Wenner (*Tauri* × *Heldreichii*) resembles *Tauri* in form and *Heldreichii* in colour. The falls are 1½ inch long, with broad, ascending wings of pale blue. The blade is small and somewhat darker in colour, the median ridge yellow, coming right to the top, and striped with white. The standards are small and spreading, of a pale blue colour; the styles are of the same hue. It is interesting to note that in both these hybrids the colour is derived from the pollen parent and the size and shape from the seed parent.

A fine lot of Crocus species, which I received from Messrs. Barr and Sons, have flowered well

are intended to remain for, say, 30 or 40 years, it is most essential that they are not over-cropped at the start, for bearing a crop of Grapes the first and few subsequent years after planting entails a great strain on the plant's energies. Whatever variety is planted, whether Muscat of Alexandria, Madresfield Court, or Black Hamburgh, the supernumeraries should be of the same variety, for then the treatment may be such as is suitable to that particular kind. Assuming that the vinery is 16 feet or more wide, the extra row of canes should be planted 6 or 8 feet from the front wall in a border specially prepared and 3 feet wide, for the first two years. The border for the permanent vines will, in usual circumstances, be made piecemeal—say, about 3 feet wide the first season. Additions to the border for the extra vines may be

here. The chrysanthus varieties are the best—namely, Sikkim, Warley and Bowles varieties. The largest flowers, however, are always seen on our native Imperati, with its two white varieties, though they are not quite so floriferous as the chrysanthus, on one bulb of which I have had seven flowers open at once. Among these species I have received *Crocus biflorus pusillus*, which is identical with a variety to be found growing wild near Naples, or more frequently near Pozzuoli, the old Puteolanum. Several years ago I found a white form of this, which could be named *C. biflorus pusillus albus*.

Varieties of *Iris reticulata* have done very well. One batch of the variety *cyanea* gave special satisfaction, several of the flowers having had four falls and standards, though I doubt whether these abnormal flowers will come true again. I have also had some very pale-blue flowers, but the finest of all were some on which the standards and style were white and the falls pale blue. Some very dark purple varieties are also handsome.

The following are the flowering dates of some Irises grown in the open here:—

- Iris alata*, December 5.
- I. alata* vars. *alba* and *marginata*, December 20.
- I. histrioides*, January 15.
- I. palestina*, January 25.
- I. persica purpurea*, February 3.
- I. Tauri* and *I. Heldreichii*, February 10.
- I. reticulata cyanea* and varieties, February 20.
- I. Statellae*, March 5.
- I. Madonna*, March 10.
- I. pumila*, March 14.
- I. rubromarginata*, March 15.
- I. obbiensis*, March 16.

Willy Müller, *Fratte di Salerno, Naples.*

CULTURE OF WATERCRESS.

THAT Watercress may be successfully grown without water is now generally accepted, and when properly cultivated under glass it is superior to the open-air product. It is during the late winter and early spring months that it is of most value, and an excellent method of cultivation is to sow the seeds in shallow boxes thickly, much as Mustard and Cress are sown, cutting the young plantlets in the same way as Mustard. A more delicious salading, with a slightly piquant flavour, is hard to obtain. *H. Rabjohn, Twicken Castle Gardens, Delden, Holland.*

CORONA DI NOVIA.

HAVING seen the enquiry in the *Gardeners' Chronicle* concerning the plant in South America called by the natives *Corona di Novia*, I may say that the name of the plant is *Spiraea lanceolata*, and it is so named in the Botanical Gardens at Buenos Aires. *H. R. Amos, Estacion Experimental, Pontaut, F.O.S., South America.*

NOTICES OF BOOKS.

TREES AND SHRUBS AT ALBURY PARK.*

IN the introduction and acclimatisation of hardy trees and shrubs successive Dukes of Northumberland, from the middle of the eighteenth century to the present time, have played an illustrious part. Their most important planting was done at Syon House, near Brentford, where there is still to be seen one of the finest collections in England, especially as regards large examples of species long introduced. It is gratifying to know that this interest is maintained by the present Duke, as is shown by the preparation and printing of

annotated lists of trees and shrubs growing on his demesne. We noticed at the time of its publication the little volume dealing with the Syon House property, and we have lately received a companion volume dealing with the trees and shrubs growing at Albury Park. It has been compiled by Mr. A. Bruce Jackson, and shows all the care and excellence that characterised the previous work.

Albury is not so famous a place in the annals of horticulture as Syon, yet this volume shows that many remarkable trees grow within its confines. It is situated five miles east of Guildford, in the valley of the Tillingbourne. We learn from the preface that it is within three miles of Wootton, the home of John Evelyn, who is credited with having laid out the place.

One of the most interesting trees at Albury Park is a Black Walnut, which has pendulous branches, but differs still more remarkably from the type (which has its fruits nearly always solitary, rarely in pairs) in bearing its nuts in clusters of so many as six. Mr. Jackson has named it *Juglans nigra* var. *alburyensis*. It is 75 feet high and 9½ feet in girth. Of the White Lime (*Tilia argentea*, syn. *T. tomentosa*) Albury possesses the finest example known; it is 109 feet high and 16 feet in girth of trunk. Two magnificent Tulip trees approach 100 feet in height. *Magnolia acuminata* is 85 feet high, a remarkable stature for this tree in the British Isles. A black Italian Poplar (*Populus serotina*) is 150 feet in height, and probably the highest in the kingdom; and a Balsam Poplar (*Populus candicans*) is 96 feet high. A specimen of the Kentucky Coffee tree (*Gymnocladus canadensis*), of which there are few large specimens in cultivation, is 44 feet high and nearly 5 feet in girth; and of *Liquidambar styraciflua*, the Sweet Gum tree of Eastern N. America, an example is of the same girth, but 68 feet high. A *Sequoia* mentioned in the *Gardeners' Chronicle* of 1879 as being then 54 feet high is now 97 feet. A magnificent pair of trees are two London Planes (*Platanus acerifolia*), respectively 112 feet and 118 feet high. *Zelkova crenata*, a beautiful Caucasian tree, has a representative 88 feet high. *Thuja plicata* (better known as *T. gigantea*) is 94 feet high and 8 feet 3 inches in girth, and we learn that a high opinion as to its timber value is held at Albury.

BOTANICAL RESULTS OF THE DUKE OF MECKLENBURG'S TRAVELS IN CENTRAL AFRICA.

A NOTICE of *Lieferungen* i.-iv. of this work appeared in the *Gardeners' Chronicle* of November 2, 1912, where the general plan of the work is described and the full German title given. In that notice the name "Mildbraed" is incorrectly given as "Milbraed." The fifth *Lieferung* is now to hand, and it contains the *Geraniales* to the *Malvales* (as classified by Engler) by various botanists. *Fagara* (*Rutaceae*), sometimes combined with *Zanthoxylum*, is represented by about half-a-dozen new species, and new and interesting species belonging to most of the families are here described for the first time. The plants figured are: *Balanites Wilsoniana* (here referred to the *Zygophyllaceae*); *Eutandropbragma speciosum* (*Meliaceae*); *Dichapetalum spathulatum*, *D. choristylum*, *D. unguiculatum*, *D. flaviflorum*, *D. Adolphi-Friedrichii*, *D. beniensis*, *D. longifolium*, *D. Poggei*, *D. brachystachyum* and *D. aruwimense*. This pantropical genus, more familiar as *Chailletia*, now numbers nearly 150 species, largely African. *Lingsheimia* is a relatively new genus of *Euphorbiaceae*, of which two species are figured. *Baccaureopsis lucida* is another new generic type of the same family, as also *Mildbraedia paniculata*. *Hippocratea* and *Salacia*, both large pantropical genera, are illustrated by new species. The imperfectly-known *Pancovia* is now proved to belong to the *Sapindaceae*, and a figure is given of *P. harmsiana*. Three new species of *Impatiens* are figured, and *I. Prainiana* is remarkable for having a slender spur 6 inches long.

TREES AND SHRUBS.

ERICA LUSITANICA.

THIS Heath is better known as *E. codonodes*. About the advent of Christmas its earliest buds commence to show white, and in the south-west towards the close of January it is in flower. Large specimens, 6 feet or more in height, are very beautiful when in full bloom, giving the impression of tall pyramids of white faintly tinged with lavender. The natural growth is erect, and the upright shoots are covered with a profusion of drooping, white, elongated bells, which have the appearance of feathery white plumes when cut. Where, however, the flower-sprays are all cut as soon as the flowers are expanded, the bush assumes a dwarfer habit, and one from which the sprays are cut every winter as soon as they are fit for indoor decoration has entirely lost its natural pyramidal habit, and has developed into a shrub 6 feet in width and 5 feet in height. In Devon and Cornwall this Heath grows superbly and propagates itself from self-sown seedlings rapidly in certain gardens, these seedlings often attaining a height of 8 feet. At one little station in Cornwall the embankment is covered with self-sown plants of *E. lusitanica*. Its foliage is of an extremely rich green, and its flowering season is a very prolonged one, lasting from Christmas, when the earliest blooms expand, until April, when the last fade. In the colder districts the plant cannot be considered absolutely hardy, since it is a native of Spain and Portugal, but south of London it is rarely injured by frost. The individual flowers have a suspicion of lavender-pink when closely examined, but this is not noticeable when they are seen crowded on the sprays of the growing plants. *Wyndham Fitzherbert, Devonshire.*

CRATAEGUS HETEROPHYLLA.

CONSPICUOUS amongst all other thorns—and, indeed, all other trees—in the Victoria Park, Bath, at the present time are several specimens of this somewhat little-known species. The two finest specimens are shapely trees about 30 feet high and as much through. They are objects of considerable interest to the numerous visitors to the park by reason of the delightful fresh green of the young leaves, which at the time of writing (March 31) are almost fully developed. In general habit the tree resembles the common Hawthorn, *Crataegus Oxyacantha*, but it has many features which distinguish it from that species. The leaves, as the specific name denotes, vary considerably both as regards shape and size, many being narrow, not more than an inch long, and quite entire, whilst others are almost cuneiform in shape and deeply cut at their apices into three or more acute lobes, these in many cases being sub-serrated. There are many variations between these extreme forms. The young leaves are very soft in texture, but become coriaceous and shiny as they mature. This characteristic alone easily distinguishes the plant from all other species. Not only is it the first to develop its leaves, but—in the collection here, at any rate—it is the last to shed them in the autumn, being quite green for some considerable time after other species have become bare. The flowers are white and borne in good sized corymbs. The fruit is large—quite twice the size of the ordinary Haw—ovate in shape, and of a fine, rich crimson colour, and usually borne in abundance. Very frequently—although not so this year—the fruit of the past season persists throughout the winter and well into the following spring, making a very effective contrast with the fresh green of the developing leaves. The plant appears to have been common at one time, as many specimens are to be found in this park, and it is mentioned by the late Dr. Hanham in his *Manual* for the park, published in 1862. *J. D. Halliburton, Bath.*

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COORSON,
Oakwood, Wylam-on-Tyne.

CATLEYA.—Plants belonging to the autumn-flowering section of Cattleyas are producing new growths, and certain of them are developing roots. Such plants should be re-potted before the roots become far advanced, or there may be a danger of injuring them. The potting compost may consist of good fibrous peat or a mixture of *Osmunda* and *Polypodium* fibres. Peat of a suitable type for Orchids is becoming very scarce, but when it may be obtained I prefer it to even the best quality *Osmunda*-fibre. Plenty of sand and broken crocks should be intermixed with the materials for potting, and the drainage should be ample to allow surplus water to drain away readily. The pots should not be larger than will just accommodate the plants, for it is not wise to use a greater bulk of potting compost than is necessary. The material should be pressed firmly about the roots and the pseudo-bulbs secured to neat sticks. Very little moisture will be required by the roots until they have become re-established in the soil, when water may be afforded liberally. Shade the plants from the direct rays of the sun or the leaves will rapidly turn yellow and drop. Spray the plants overhead whenever the conditions are favourable, and keep the atmosphere humid by damping the spaces between the pots. The presence of atmospheric moisture will help to keep the shoots plump until the roots can gather moisture again after their disturbance. Certain varieties of *C. Warszewiczii* (syn. *gigas*) are very irregular in their flowering, and I am inclined to the opinion that these shy-flowering Orchids are all imported from a particular locality. If the plants are started in a dry, well-ventilated house at the present season, exposed to the full rays of the sun during the whole of the summer and syringed freely each day, they will bloom with more regularity. The flowers from shy-blooming plants are usually larger and superior in quality than those from such as flower regularly under ordinary treatment. The spikes of summer-flowering Cattleyas, *Laelias* and their hybrids are prominent. Such species as *C. Mossiae* and *C. Mendelii* require careful attention as the flower-buds advance in the sheath, for moisture accumulating in the latter would cause the flower-buds to rot and decay. This may be prevented by cutting away the flower-sheath just above the flower-buds or by carefully splitting it open horizontally from the base to the top. As the plants come into flower place them where they will be well exposed to the light, but as soon as the flowers expand grow them in cooler and drier conditions and afford shade, as this treatment will improve the quality of the flowers and cause them to remain fresh for a long time.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOTE,
Eastwell Park, Kent.

RASPBERRIES.—As soon as the new growths are sufficiently advanced they should be thinned, in order to concentrate the energies of the plants into those canes required for fruiting. After thinning to the number of shoots required, those that develop subsequently can be chopped off with the hoe when keeping the plantation clear of weeds. If a dressing of farmyard manure was not afforded established plants during the winter, it should be applied at once, or, failing this, a dressing of artificial manure, working the materials in the soil lightly with the fork or hoe. The manure is best applied when the weather is dull or showery. Young canes that were planted during last autumn or winter should be cut to the ground level. As soon as the new shoots are sufficiently advanced, thin them to three or four of the strongest for each root, as this number will be ample for the first season.

LOGANBERRIES AND BLACKBERRIES.

Recently-planted specimens of these fruits should be afforded the same treatment as recommended for Raspberries. The new shoots will grow vigorously from the start, and the energies of the plants be directed into the building up of strong fruiting canes for next year. See that newly-planted canes do not suffer from lack of moisture in hot weather and when drying winds prevail. Watering the roots at such times will assist the plants greatly, and in conjunction with a light mulching of animal manure carry them through till well rooted.

PLANTING FORCED STRAWBERRIES.

The later batches of Strawberries which have not been unduly weakened by hard forcing are first-rate for planting in the fruit garden. Before doing this, however, harden the plants gradually by affording them the protection of a cold frame for a week or two after the fruits have been gathered. If red spider or mildew is present on the leaves, dip the plants in an insecticide, or a mixture of sulphur, at the time of moving them from the houses. When planting Strawberries that have been forced, break the ball of soil about the roots with a strong, pointed stick. When this is done the roots grow quickly in the new soil. If the ground is of a heavy nature, and the surface lumpy, place a little discarded potting soil or wood-ash about the roots at the time of planting. First prepare the ground as recommended in previous calendars, and if the planting is done when the weather is hot and dry, water the roots and continue to apply moisture as required. When the work of planting is finished, rake the surface and afterwards hoe the bed on frequent occasions in suitable weather. Varieties such as *Royal Sovereign* and *Viscomtesse Héricart de Thury* when planted in this way produce trusses of fruit the following autumn, and if the weather is favourable for the berries ripening, the latter offer a pleasing addition to dessert fruits at that time.

EARLY STRAWBERRIES.—Small batches of an early variety, such as *Royal Sovereign*, planted on a warm, sheltered border, will afford berries in advance of the general crop. Always select very strong plants for the purpose; feed the roots now with a little quick-acting artificial manure, and place straw along the rows as litter. The protection of frames or odd lights will hasten the development of the flower trusses, which should be thinned to a very moderate number.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

STENTANTHIUM ROBUSTUM AND CRAMBE

CORDIFOLIA.—These are two grand subjects for planting in clumps on the margins of lakes, ponds, or streams in association with *Water Lilies*, *Glyceria spectabilis*, *Iris Monnieri*, *I. ochroleuca*, and the newer *Iris* hybrids raised by the late Professor Michael Foster. The following *Water Lilies* are worthy a place in every collection, however small:—*Marliacea carnea*, *chromatella*, *sulphurea grandiflora*, *albida*, *igneae*, *Gladstoniana*, *candida*, *gloriosa*, *W. Falconer*, *Robinsoniana*, and the sweet-scented *Nymphaea pygmaea*, the last for shallow water.

HARDY FERNS.—This is the best time to transplant or to divide deciduous Ferns. Large plants growing wild in woods may be dug up with balls of earth and replanted in suitable situations in the wild garden, such as beneath the shade of trees or near to rocks. Large-growing *Lastreas* have a special charm, and may be removed now without experiencing much check to growth.

MICHAELMAS DAISIES.—Perennial *Asters* should be divided annually, or at least biennially, if flowers of the best quality are expected. If grown in permanent beds on the grass, as at Madresfield Court, some of the old soil should be removed, replacing it with fresh, loamy compost, the beds trenched and a thick layer of decayed manure placed at the bottom of the trench, for *Michaelmas Daisies* are gross feeders. *Amelius Riverslea*, *St. Egwin*, *Finchley White*,

Beauty of Colwall, *ericoides*, *E. Beckett*, *Nancy Ballard*, *Peggy Ballard*, and *Mrs. Rayner (red)* are all good varieties. A little bone-meal added to the staple will prove beneficial. If annual or biennial division is not practised, the next best thing is to thin out the young growths to at least 7 to 10 inches apart.

LILIUMS.—We have never been quite successful in bringing *Liliums* through the winter and spring, neither those planted on our heavy clay nor in prepared beds. In these circumstances we have in recent years started them singly in pots (now ready to plant out) with greater success, especially *L. longiflorum*, *L. speciosum*, and *L. auratum* varieties. It is necessary to dust around the plants on frequent occasions with fresh soot, in order to preserve them from damage by slugs and snails.

VIOLETS.—As the plants of *Princess of Wales* or *Kaiser Wilhelm* type pass out of flower secure healthy, vigorous runners for next season's stock. Plant them in well-manured 5-foot beds, allowing a distance of 1 foot from plant to plant. Stick a few stout branches from evergreens in amongst them for providing shade and shelter from cold winds.

LATHRAEA CLANDESTINA.—This exceedingly quaint parasite is in full flower, growing upon the partially bared roots of a *Weeping Willow*, *Salix babylonica*. It is not a difficult plant to cultivate, although it requires several years to become established. Specimens thrive here planted in the ordinary way, in a moist place, amongst the larger roots of the *Willow*.

RECENTLY TRANSPLANTED SHRUBS AND

TREES.—Trees and shrubs that were transplanted in clayey soil during March or early in April, whilst the ground was wet with constant rains, should be mulched with half-decayed manure, or, failing that, lawn mowings, after the surface has been first loosened by the Dutch hoe. This will conserve the natural moisture in the soil, preventing rapid evaporation by drying winds.

FLOWERS IN SEASON.—The following shrubs and trees are in their full beauty in these gardens:—*Spiraea arguta*, *S. multiflora*, *S. Albertii*, *Magnolia Soulangeana*, *M. conspicua*, *M. ovata*, *Lennei*, *M. stellata*, *Halleana*, *Pyrus Malus floribunda*, *P. atrosanguinea*, *P. Scheideckeri*, *Cerasus Gauntlettii*, *Prunus Padus*, the *Bird Cherry*, *P. Watereri*, *P. H. J. Veitch*, *P. serrulata*; the newer Japanese varieties of flowering *Cherry*, such as *Lida nova* and others; *Double-flowered Peach*, *Gorse*, and various *Heaths*. Amongst bulbs in grass, those in flower include the early section of *Dutch Tulips*, *Hyacinths*, *Daffodils*, *Narcissus poeticus* varieties, *Muscari* (*Grape Hyacinths*), *Scilla nutans* and *S. hyacinthiflora alba*.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY,
Knowsley Hall, Lancashire.

BOUVARDIA.—Plants that have been cut back and rested are growing afresh, and may be repotted. Remove a portion of the old soil, and repot the plants into receptacles sufficiently large to accommodate the roots. For soil use a mixture of equal parts loam, peat and leaf-mould, adding sufficient sand and charcoal to keep it porous. Place the plants in a pit having a temperature of 60° and a moist atmosphere. Syringe frequently, and pinch out the points of the shoots when they have grown 4 inches long. Specimens raised as rootlets may be potted in small pots; when the plants are established pinch the leading shoot if bush specimens are required, but not for standards.

LANTANA.—These evergreen, shrubby plants are of easy culture, and may be propagated either from seeds or cuttings. Seeds may be sown now in well-drained pans, barely covering them with soil. Germinate them in a temperature of 70°. Cuttings may be rooted at this season in a peaty compost under a bell glass. Shift the plants into pots when rooted, and grow them in a temperature of 55° to 60°. Pinch out the points

of the shoots to induce a bushy habit. Afford increased root-room as required, putting them finally into 5 or 6-inch pots. Pinch out all the flowers until five or six weeks before the blooms are required, then feed with liquid manure and concentrated fertiliser, using them alternately.

CYTISUS RACEMOSUS.—When the flowers are over prune the shoots to form shapely specimens and grow the plants in a temperature of 55° to 60°, syringing them freely on bright days. In about a fortnight new growth will appear, and specimens requiring re-potting may be attended to. Reduce the ball of soil slightly by means of a pointed stick and re-pot in a compost consisting of two-thirds loam and one-third peat and grit. The plants are best grown under glass until July, when they may be plunged out-of-doors in a bed of ashes until October to allow the wood to ripen. Cuttings struck now make useful plants in 18 months' time. Insert the cuttings singly in thumb-pots filled with sandy soil and mixed with a little peat-dust, and cover them with a bell-glass. When rooted re-pot them as required and pinch any shoots that grow unduly strong to preserve a good balance of growth. Rooted cuttings should be treated as advised for older specimens. The stock may also be increased from seeds sown now, but cuttings are to be preferred and do not grow so straggly. *C. canariensis* is useful as a succession to *C. racemosus*, for plants will flower from May onwards. The propagation and cultivation is the same in both cases.

EUPHORBIA JACQUINIAEFLORA.—This species should be grown in a temperature of 75° to 80° with sun heat to produce cuttings. Plunge the cutting-pots in a brisk bottom heat.

CALLICARPA PURPUREA.—Plants that were cut back in the spring have made shoots suitable for cuttings, and these should be dibbled into pots and rooted in a propagating frame. When rooted shift the plants into 2-inch pots filled with a compost consisting of two-thirds loam, one-third peat and sufficient sharp sand and broken charcoal to ensure porosity. Stop the growths at intervals to form bushy specimens, unless it is intended to train them as standards. When they have attained to the desired height pinch out the point and stop each subsequent side-shoot when two or three pairs of leaves have developed. Remove all flowers until August, but those that develop after that time should be allowed to remain. The blooms will be quickly succeeded by the bright purple berries, which are attractive from October to the following spring. Old plants may be re-potted and treated as advised above.

FRUITS UNDER GLASS.

By W. HEOLEY WARREN, Gardener to the Aston Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

VINES.—Red spider may make its appearance in houses that are being kept drier because the Grapes are ripening, and the pest must be guarded against. If the borders are allowed to become the least dry an attack of this pest is almost sure to follow. Therefore examine the soil occasionally, and when moisture is needed afford water copiously during the early part of the day when the maximum amount of air is afforded, for ventilation will prevent the rising moisture from settling on the fruit. After watering the roots place a thick mulch of half-decayed leaves or manure from a spent Mushroom bed over the surface to retain the moisture about the roots and prevent undue evaporation. Maintain a mild, genial atmosphere in vineries where the berries are swelling. Make the most of the sun's heat on fine days by closing the ventilators early in the afternoon. Attend to the work of disbudding, stopping, and tying the shoots of later vines. On bright days keep the fires low; for the use of fire heat when the sun is shining is not only unnecessary, but harmful to the vines. Now is a suitable time for making fresh borders for planting young vines that are being raised during the present season, as these will require planting in a few weeks. Make the borders about 3 feet deep, and employ fresh maiden loam, adding about 10 per cent. of $\frac{1}{2}$ -inch bones. If the loam is adhesive in texture, employ the bones and add about the same quantity of old lime rubble and crushed bricks. Spread out the roots, cover them with a thin

layer of soil, and soak the border with water warmed to about 100°. Keep the house close until the roots are well-established, when the treatment may be the same as for established vines. Plants that have been raised from eyes inserted in pieces of turf may be planted without disturbing the roots by simply inserting each turf level with the surface, and pressing soil firmly about them.

PEACHES AND NECTARINES.—Trees with fruits at the stage of the second swelling need most careful attention in watering, especially where the border is inside the house. If moisture is necessary let the water be warmed to about 90°, the quantity to be determined by the condition of the soil and the energies of the trees. If the border is well drained, and the soil light and free in texture, some form of liquid manure may be afforded in liberal quantities, say once weekly; but if a mulch of partly-decayed manure is spread over the surface there will be less need to use the manure water. Close the house sufficiently early in the afternoons of sunny days to secure a temperature of about 85°, and syringe liberally with soft, clear water warmed to the same temperature as the atmosphere of the house. Proceed with the thinning of the fruit in successional houses in accordance with the condition of the trees. Those that are weakly should only be allowed to carry moderate crops, and every assistance should be afforded such trees by surface dressings and applications of liquid manure; but vigorous trees, or such as are young and growing in newly-made borders, may be allowed to carry heavy crops. Adopt every means to keep insect pests in check.

ORCHARD HOUSE.—Maintain a moist, genial atmosphere in orchard houses in order that the trees may grow freely and swell their fruits. On warm mornings syringe the trees early and freely, but if the weather is cold keep the atmosphere somewhat drier. Ventilate the house early and gradually, but do not allow cold draughts of air to reach the plants. Close the house between 2 and 3 p.m. if it is safe to do so. Water any of the pot trees that require moisture and syringe them copiously. Admit air in the mornings when the temperature has reached 60°, and allow it to rise to 80° or thereabouts. No danger need be apprehended by a high sun temperature, with proper ventilation; on the contrary, if attention be paid to keeping the atmosphere of the house moist, it will be of the greatest benefit to the trees. Disbud and pinch the young shoots when necessary, but do this work gradually and often, for the removal of many shoots at one time is harmful. Pinch the stronger shoots first and the weaker ones afterwards. Where the fruits are very thick, thin them gradually. Guard against the presence of harmful insects, and if aphids is present fumigate the house or spray the trees with clear water, or dust the infested branches with Tobacco powder, this being an excellent specific for the destruction of both black and green fly.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

OUTDOOR TOMATOES.—To have strong plants for culture out-of-doors they must not be stinted for pot-room, and should not be over-watered, the objective being very stout short-jointed plants that will fruit at the earliest possible moment. A layer of cinders for the pots to stand upon obviates the necessity of much watering, but watering is a practice which observation alone enables one to understand, to hit the happy medium of giving just enough to keep the plant moving sturdily, without on the one hand inviting grossness or on the other an insufficient food supply.

PEAS.—From this time Peas are almost wholly grown on ground from which a crop such as Broccoli has been cleared. Instead of trenching all the ground, only that to be occupied by the Peas is trenched, the top spit being turned over on one side and the bottom spit dug and left in the bottom. If the soil is known to require manure let the dung be incorporated with the lower spit, but usually I find ground in good heart needs no further

aid to fertility. I have known a 6-inch layer of rotted manure to be placed in the bottom of the trench, but in our soil, however helpful it may be elsewhere, it is of no advantage. The Peas are arranged in a wide furrow 6 inches below the surface, the soil having previously been trodden firmly to provide the necessary cohesion, and conserve the moisture from rains or waterings. They are covered with 3 inches of soil, leaving a depression of about 3 inches, into which liquid can be poured without losing any of it. I know no better variety for general use than Sharpe's Queen, and along with it for late sowing Gladstone and Autocrat. The last-named seems to be quite mildew-proof. Following Broccoli the trenches are made in every third furrow of that crop, and after the Peas are sown, and supports placed along the rows, the interspaces are dug for catch-crops of Lettuces, Spinach and Turnips.

GENERAL REMARKS.—Clear away winter and spring crops as soon as they become non-productive. It is not only a means to conserve the fertility of the soil, for in the later stages of a plant's existence it exhausts fertility more than when young, but the practice can be commended because it enables work to be carried on more expeditiously and systematically. Even if time cannot be spared at a particular date to finish clearances, by cutting over with an ordinary switching knife exhausted Brussels Sprouts and other crops the toll on the soil is terminated, and the tops will become lighter every day by evaporation. Spinach is destroyed by means of a sharp hoe run along each row just under the surface, and this crop, if not too far over-grown, may be dug into the ground as a manure. Digging and trenching at this time of the year should be carried out early in the day, and, if possible, in dull weather. Nothing is gained by exhausting men's strength by working them hard in the hot hours of the day, unless necessity imposes. All crops in the seedling stage, such as Parsley and Leeks, should be hoed often, and any weeds that cannot be reached among the plants removed by hand.

THE "FRENCH" GARDEN.

By PAUL AQUATIUS.

HOT-BEDS.—The bulk of the Lettuces grown on hot-beds have been marketed, and the frames need ventilation daily, and even at night in calm weather. Carrots require watering at least once weekly, and to expedite this operation all the lights may be piled up on the end ones of each row and the watering done with the hose. It will be necessary, owing to the increase of growth, to raise the frames one or two inches higher by placing wisps of straw under each corner. The paths may be filled during the present month with dry manure in order to prevent the soil from rolling off when removing the frames and lights early in May. Now that the Turnips are growing fast ventilation may be afforded both day and night, and the lights removed entirely in bright weather. The soil should be kept just moist until the roots swell, when a greater amount of water may be afforded.

OPEN-AIR CROPS.—Sow the first batch of Turnips in drills made 10 to 12 inches apart. Such sorts as Snowball, Early Milan, and White Martean are suitable. A better growth will be obtained where the beds are top-dressed with black soil. The disadvantage of this first batch is the proneness of the plants to bolt; last year all those sown before April 10 were failures owing to cold, wet weather. Cabbages are ready for market only a few days earlier than last year, despite the milder winter. The variety Early Market was grown exclusively and not one plant bolted, which speaks well for the variety; the seeds were sown on July 23, and the ground is very light. The Lettuces (January sown) are ready for planting out, but this must only be done if the plants are well hardened, as they are more tender than those sown in October. There will be pressure of work later with the Melon crop, therefore all planting and sowing should be completed at an early date, for it sometimes happens that Melons are neglected during May owing to arrears of work.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR MAY.

FRIDAY, MAY 1—

Dundee Hort. Assoc. meet.

TUESDAY, MAY 5—

Rov. Hort. Soc. Coms. meet. and Nat. Tulip Soc. Show. (Lecture at 3 p.m. on "The Value to Gardens of some of Mr. Wilson's Introductions from China.") Hort. Club dinner, 6.30 p.m. (Lecture on "Indian Garden Craft," by Mrs. Patrick Villiers-Stuart.) Scottish Hort. Assoc. meet.

WEDNESDAY, MAY 6—

B.G.A. Ex. Council meet.

THURSDAY, MAY 7—

Linnæan Soc. meet.

MONDAY, MAY 11—

United Hort. Ben. and Prov. Soc. Com. meet.

THURSDAY, MAY 14—

Manchester and N. of Eng. Orchid Soc. Ann. Meet.

TUESDAY, MAY 19—

J. Hort. Soc. Spring Sh. at Roy. Hospital Gardens, Chelsea (3 days).

WEDNESDAY, MAY 20—

Roy. Nat. Tulip Soc. Sh. at Roy. Hospital Gardens, Chelsea (2 days).

MONDAY, MAY 25—

Linnæan Soc. Anniversary meet. at 3 p.m.

Rhododendron Sh. at R.H.S. Hall (5 days).

THURSDAY, MAY 28—

Bath and West and Southern Counties Soc. Sh. at Swansea (5 days). Royal Botanic Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 49.4°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, April 22 (6 p.m.): Max. 65°. Min. 50°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, April 23 (10 a.m.): Bar. 29.7°; Temp. 55°. Weather—Dull.

PROVINCES, Wednesday, April 22; Max. 63°, Shields; Min. 52°, Chester.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Hardy Bulbs in variety, at 12; Carnations, etc., at 1.30; Japanese Lilliums at 4; Palms and Plants at 5. At 67 and 68, Cheapside, E.C., by Protheroe and Morris. Orchids at Walton Grange, Stone, Staffordshire, by order of W. Thompson, Esq., by Protheroe and Morris at 1.

FRIDAY—

Established Orchids, by Protheroe and Morris, at 12.45.

State Afforestation.

The capacity of Englishmen for taking sides, considered as a national characteristic, has much to be said in its favour. It gives a zest to politics, and makes amusements tolerable. The quality has its drawbacks, however, and when it is manifested in controversies, such as that on State afforestation recently engaged upon in the columns of the *Spectator*, it is apt to make the less argumentative despair. For as we have endeavoured to show on more than one occasion, State afforestation is required urgently in these islands.

The controversy to which we have referred must, however, do good, for although the protagonists on either side were doughty in debate, it does not seem open to us to doubt but that the honours rest with the "ayes," led by Sir John Stirling Maxwell, as against the "noes," who number in their ranks the Duke of Northumberland and Mr. Elwes.

The correspondence is published in part in the April number of the *Quarterly Journal of Forestry*, and although we could have wished that it had been published *in extenso*, a fair reading of the argument must, we think, lead to the conclusion that the case for State afforestation is—once again—made good. The main lines of argument used by Sir John Maxwell are not to be controverted. They are that the world's timber supplies are ceasing to meet the world's demands, and that prices are rising in consequence: that the evidence of the better part of a century of State afforestation in Germany shows that forest returns rise as management becomes more efficient: that the returns to be obtained from a properly managed estate, though not high, are such as is to make afforestation, even at present timber prices, a profit-yielding investment: and that apart from monetary returns, the gain in rural population is so certain and so valuable that even though afforestation but paid its way it would yet be the duty of the State to undertake it. As Sir John Maxwell puts it, "no one who knows the Vosges or the Jura, Saxony or Bavaria or the Belgian Ardennes, can doubt that forestry is the one sure anchor of rural life in a rough hill country. In the Highlands of Scotland it offers the only reasonable hope of settling small holders in the glens—because it is the only industry to which they can turn for winter employment." It is, of course, open to the polemical to make argumentative use of the fact that the advocates of State afforestation seek to underpin their faith in the commercial promise of afforestation by means of arguments relating to national welfare. But we have yet to learn that this is unscientific. It is not in serious dispute that a rural problem exists. No one who talks with British men of peasant stock settled successfully in Canada or the United States can be unaware that they went abroad, and would not return, because they found in the new country rural occupations and rural conditions which gave them scope. If afforestation, therefore, did something—as it would assuredly—to stem this tide of the emigration of the fittest, that also must be reckoned in casting up the balance sheet of afforested areas. Apart, however, from this argument, which some call sentimental or patriotic, or uneconomical, though it is in fact an economic argument of indubitable cogency, there is enough evidence to show that a properly managed forest brings in a moderate and sure return, and for that evidence we refer our readers to the record of the recent controversy as republished in the official *Journal* of the Royal English Arboricultural Society.

"The Rose Annual."

The members of the National Rose Society have received during the past few days *The Rose Annual* for 1914, a volume of 185 pages. The first article is by M. Jules Gravereaux, the well-known president of the French Rose Society, and it

contains a description of his Rose garden at L'Hey, near Paris, in which is grown the most complete collection of Roses in the world. The last edition of his catalogue of the Roses there cultivated, published in 1902, enumerated 6,781 species and varieties, and these have been largely added to since, so that the collection now includes about 7,500 varieties. The article is accompanied by a plan and photographs of the garden. Later in the volume we find an article by another Frenchman, M. Pierre Guillot, on "The Rose in the Ornamentation of Gardens," while distant lands are represented by a "Jotting" by Mr. R. H. Nicholson, on "Rose-growing in China."

A feature of this year's Annual is the treatment of certain subjects by a number of different writers, so that an endeavour is made to present the questions dealt with from different points of view. Thus we find articles on the classification of Roses from nine contributors, five more deal with mildew and black spot and the treatment of these diseases, whilst Mr. Darlington writes an article on autumn-flowering pillar Roses based on the reports of some sixteen observers in different parts of the country.

Seeing that the National Rose Society is contemplating taking up the difficult subject of classification, the editor of the *Annual* has no doubt been wise in publishing these articles on the matter, so that the subject may be thoroughly considered before any action is taken. We hope in a future number to discuss the views presented by the several contributors.

The writers who have discussed mildew and black spot deal with the matter in very different ways, but certain broad principles seem to emerge on which all or most of them agree. These we venture to sum up as follows:—(1) There is very little benefit derived from winter spraying; (2) mildew may be checked or occasionally cured by treatment, but in the case of black spot treatment is of little use to cure the disease, though it may prevent it spreading to other plants; (3) black spot is a very serious and sometimes fatal malady; (4) in both cases the best results are likely to be obtained by preventive rather than remedial measures. Preventive measures may include early and persistent syringing and the breeding of plants immune from the disease. Dr. Waddell takes exception to the generally received view as to the fungus causing mildew, namely, that it is caused by the fungus *Sphaerotheca pannosa*, which is seen in the early part of the season as a powdery appearance on the leaves, afterwards attacking the buds, and later still the thorns and stems, in the two last-named cases the mildew appearing as a more or less felted covering, in mild winters sometimes persisting till spring. He regards each of the three attacks as due to a distinct fungus. (1) The powdery mildew, he holds, is caused by the hop fungus, *Sphaerotheca hamuli*; (2) the felted mildew on buds and stems by *Sphaerotheca pannosa*; and (3) the mildew attacking thorns and stems to a third species

PERGOLA
(FROM "THE HORTICULTURAL RECORD")

of *Sphaerotheca* as yet unnamed, which he provisionally calls "thorn mildew." Dr. Waddell, however, admits that the powdery mildew (his *S. humuli*) grown on the Rose will not germinate on the Hop, and does not give any proof that the Rose mildew cannot (as is usually supposed) change in character as the season advances. Until, therefore, the contrary is proved rosarians will in all probability continue to regard any of the three forms as "just mildew" to be got rid of as best they may, and equally objectionable by what name soever it ought strictly to be designated.

Besides these questions a number of matters of interest to rosarians are dealt with in various articles. Dr. Williams tells us how to breed new Roses, Mr. Courtney Page how to bud them, Dr. Lamplough how to treat them the first year after planting, and Mr. Easlea why they sometimes fail to prosper, while Mrs. Darlington treats of the lasting qualities of cut Roses, and incidentally how to make them last as long as possible. We may surmise she would by no means approve of the rule observed in the garden of Mr. J. Gravereaux, namely, that no flower shall be cut, for she holds that it is a satisfactory point in using Roses for the house that, as a rule, they last better when cut than they do in the garden.

A word should be said of the jottings, or short notes, from different members of the society. Mr. G. M. Taylor, who contributed to these columns [January 31, 1914, p. 69] an interesting note on the value of *Rosa laxa* as a stock specially suited for light soils, refers to the subject again in the *Annual*. Some six years ago we employed this stock for some of the yellow-hued Roses with which we had found difficulty. The results were good, but they were better even when the same stock was used for climbers of the *Wichuraiana* type. *Rosa laxa* stocks produce enormous root systems, and with the vigorous climbing Roses a balance of systems is maintained which appears very favourable to the Rose, at least on light soils.

Miss M. E. Curle contributes a useful note on the relative hardness of climbing Roses in Scotland. Besides a number of photographs, the book contains six photographs of Roses in colour. These are a considerable advance on those of last year, but are a long way as yet from expressing the colours of the Rose and its foliage. Still, some of the pictures—those, for instance, of the Roses Mrs. Edward Mawley and Mrs. John Laing—are beautiful as pictures of individual flowers.

Supplementary Illustration.—Our Supplement is reproduced from Mr. CORY's volume, *The Horticultural Record*, and illustrates a pergola exhibited by Messrs. J. CHEAL AND SONS at the Chelsea Show of 1912. The exhibit consisted of a paved court with a pool, displaying twin fountains in the centre, the margins and approaches being of stone paving. A clipped Yew fence formed one boundary, a stone wall supporting a raised terrace the other. The pergola tastefully festooned with Roses, vines, and Clematis converged on a dial plateau which

faced a garden resthouse. On either side of the formal garden, but screened therefrom, were rock gardens and pools suitably placed, the whole forming an effective garden retreat.

CITY OF LONDON ROSE SOCIETY.—We have received a copy of the Book of Arrangements of the City of London Rose Society, including the schedule of prizes to be awarded at the second annual exhibition, which will be held at Cannon Street Hotel on Thursday, June 25. The report and balance-sheet for the first year show excellent results, and the society has met with such encouragement and support that its future seems assured. The sum offered for prizes totals close upon £100, and eight Challenge Cups are offered for competition. There are several additional classes this season. Following the precedent established by his predecessor, Sir DAVID BURNETT, Bart., the present Lord Mayor, Sir VANSITTART BOWATER, has become President of the society during his term of office, and has con-

EXHIBITION OF PRINTING AT THE ROYAL AGRICULTURAL HALL.—The Printing and Allied Trades' Exhibition to be opened at the Royal Agricultural Hall by the Lord Mayor of London on May 13 promises to be the largest exhibition of its kind ever held, every available space being occupied with exhibits strictly appertaining to the graphic arts. New machinery and appliances will be shown alike interesting to the expert and the general public, in addition to a very fine display of specimens of printing of all processes, including photogravure. The exhibition will remain open until May 30.

THE CINEMA AS AGRICULTURAL INSTRUCTOR.—The use of the cinema as a means of agricultural instruction is being considered in Belgium, and M. HENRY, of the Central Belgian Society of Agriculture, is preparing a scheme. The chief difficulty in the matter is the present scarcity of suitable films, but this is being solved by the preparation of a number of special ones for the

FIG. 126.—RAISED TERRACE WITH DAFFODILS AND SHRUBS, EXHIBITED BY MESSRS. JAMES CARTER AND CO. AT THE R.H.S. MEETING ON APRIL 15, 1914.

sented to open the exhibition. The Hon. Sec. is Mr. A. E. PROTHEROE.

HIGHGATE CHRYSANTHEMUM SHOW.—The annual exhibition of the Highgate and District Chrysanthemum Society will be held on Thursday and Friday, November 5 and 6, at the Highgate Hall, Highgate. The secretary is Mr. E. F. FENWICK.

NECTRIA DITISSIMA.—A note by the editor in the current issue of the quarterly *Journal of Forestry* (April, 1914), draws attention to the fact that *Nectria ditissima*—the fungus associated with Apple canker—has been specially prevalent during the past autumn and winter. Specimens of the fungus growing both on Apple and Ash have been received by Professor SOMERVILLE, who would be glad if gardeners and others would keep a look-out for the fungus during the coming autumn and send any specimens found growing on trees other than the Apple to him at the School of Rural Economy, Oxford.

purpose. The proper working of agricultural machines and implements, the pruning of trees, the destruction of insect pests, and many other processes will be shown on the screen.

SWISS NATIONAL PARK.—The States Council has voted almost unanimously for the creation of a national park in the Basse-Engadine. The park will extend over 200 square km. of ground at the extreme south-west of the Grisons, between the River Inn and the Italian frontier.

NATIONAL HORTICULTURAL SOCIETY OF FRANCE.—We have received the annual list of members of this Society. It is a bulky volume of 248 pages, uniform with the *Journal* of the Society. It contains a report of the Society's general meeting held in December last, an account of the past year's work, the rules and details of the various sub-committees. The lists of members begin at page 45. In addition to the name and address, the year of admission of each member is added, and also a note in italics of such specialities as the member may be interested in.

The volume is an extremely useful work of reference for those who have business relationships with the Continent.

ST. PETERSBURG EXHIBITION.—The date of this show has been postponed until May 26 on account of the unfavourable spring. Under the auspices of the National Horticultural Society of France an excursion will be organised for the benefit of its members. It is proposed that a start be made from Paris on May 21. The party will reach Berlin on the 22nd and St. Petersburg on the 24th. After spending four days at St. Petersburg the party will leave for Moscow on the 29th. A couple of days will be spent there. On June 1 the party will depart for Warsaw, and from there proceed to Vienna, thence to Munich, returning to Paris on June 11. The inclusive cost of the trip is £42 per person.

SPRING FLOWERS AT BELVOIR.—The spring flowers at Belvoir Castle are now in full beauty, and will continue for several weeks. The mild winter has been much in their favour, and the present display excels all previous years. Rhododendrons Falconeri, Thomsonii, and campanulatum are flowering well, also many of the early-flowering hybrids, and Camellias. The Duchess Garden is open to the public every day except Sundays.

MILK FROM SOYA BEANS.—With the increasing demand for fats—a demand which is due to various causes, among others the greater consumption of fatty foods and the increase in habits of personal cleanliness, or rather of washing with soap—the vegetable world is being ransacked for supplies to meet the demand. Cocoanuts are being planted over wide areas of the Tropics and other Palms are being made to yield their oil to the soapmaker. Flax is becoming more profitable, and now it is claimed Soya beans are being used for the manufacture of vegetable milk. The synthetic milk is said to be indistinguishable by sight or taste from the milk of the cow. To make the resemblance complete beneficent bacteria which occur naturally in cow's milk are introduced into Soya-bean milk, with the result that the latter behaves in all respects like the former, yielding "butter" and "cheese," the quality of which is said to be excellent. The synthesis of this milk-like fluid is the more remarkable since, as stated in a notice in the *Times*, the first consignment of the Soya bean reached Europe so recently as 1906. To-day the imports are of the value of a million pounds per annum, and amount to about a million tons. China, Japan, Korea and Manchuria supply the Western market, and the beans enter into the composition not only of milk, but also of other foodstuffs, such as biscuits and oil-cake. Formerly, therefore, the cow was the necessary intermediary between the Soya bean and the milk; now the cow is replaced by the chemist. If, as is stated, the synthetic Soya milk is as good as the ordinary article, the fact that the chemist can perform the intermediate operations in his laboratory more cheaply than the cow in hers, it may prove "so much the worse for the cow," and must prove a boon of inestimable value for the poor.

SALE OF GARDENING BOOKS.—At a sale of books and manuscripts held at Sotheby's Rooms on the 6th, 7th, and 8th inst. the following were amongst the works disposed of:—JOHN GERARDE'S *Herball, or General Historie of Plantes*, first edition 1597, engraved title, with autograph signature of DAINES BARRINGTON, £3 5s. (SOTHERAN); J. PARKINSON'S *Paradise in Solo, Paradisus Terrestris, or a Garden of All Sorts of Rarest Flowers*, with numerous woodcuts, 1656, £6 (EDWARDS); F. SANDER'S *Reichenbachia; Orchids Illustrated and Described*, 192 coloured plates; mounted on black boards, 1888-94, £18 10s. (EDWARDS); MRS. A. GATTY'S *British Sea Weeds*, 2 vols., 1872; E. J. LOWE'S *Beautiful Eaved Plants*, 1872, and LOWE'S *Our Native*

Ferns, 2 vols., 1865, 9s. (HILL); J. C. LOUDON'S *Arboretum et Fruticetum Britannicum, or the Trees and Shrubs of Britain*, 8 vols., 1865, 5s. (HERMAN); J. SEBOTH'S *Alpine Plants, Painted from Nature*, text by F. GRAF, 4 vols., and F. BOYLE'S *About Orchids*, 1893, and others (8 vols. in all), £2 16s. (JAMES); J. SOWERBY'S *English Botany*, 3rd edition, enlarged, 12 vols., 1877-86, £13 (HOPKINS); J. SOWERBY'S *Grasses of Great Britain*, E. J. LOWE'S *Natural History of New and Rare Ferns*, 1871, and Rev. M. J. BERKELEY'S *Handbook of British Mosses*, 1863, £1 2s. (THORP); J. BATEMAN'S *A Second Century of Orchidaceous Plants*, with numerous coloured plates, 1867, 11s. (BROWN); LA MAOUT'S and DECAISNE'S *General System of Botany*, translated by Mrs. HOOKER, with numerous illustrations, 1876, £1 15s.; *Botanic Garden: Representations of Hardy Ornamental Flowering Plants*, by B. MAUND, 8 vols., 1825, 16s. (THORP); *Illustrated Dictionary of Gardening*, by G. NICHOLSON, 4 vols. in 2, 1885-7, £1 10s. (HILL); *The Rhododendrons of Sikkim-Himalaya*, by J. D. HOOKER, with fine coloured plates, 1849, £2 (WELDON) and *Indigenous Flowers of the Hawaiian Islands*, by Mrs. F. SINCLAIR, with coloured plates, 1885, 12s. (HILL).

A NEW SPRAY FLUID.—Dr. MAX ISSLEIB, writing in *Möllers Deutsche Gärtner-Zeitung*, suggests the use of the jelly-like matter produced by boiling certain algae in water for the purpose of a spray fluid. He points out that when certain marine algae (*Chondrus crispus* and *Gigartina mamillosa*) are heated with water, 2.52 parts of the former with 100 of the latter, a gelatine-like fluid is produced which, sprayed on plants, sets to form a thin skin, in which insect pests are entangled and destroyed. It may be mixed with 5 or 10 per cent. petroleum or paraffin. The substance recommended is one which has many applications. We ourselves have it in common use for the stiffening of jellies and the like, and its properties are indeed remarkable. The fisherfolk of Brittany collect the red seaweed *Chondrus crispus*, expose it on the grass to dry and bleach, and send it to Germany, where, as we are told, it is used to give body for jam. The consistency of the jelly which it makes is, of course, determined by the amount of water which is added to the dry seaweed. In our household about as much as may be held in a teaspoon serves to make the "body" of a large dish of jelly. The proposal to use this simple-specific is one which certainly deserves attention, but whether its powers of adhesion are better than those of the substances in general use remains to be determined. An objection which occurs to the mind is the general one that in wet weather the jelly-like skin formed when the stuff is sprayed on the plant would swell and wash off. As, of course, is well known, this property of many seaweeds to form with boiling water a gelatine-like jelly is utilised in many ways in medicine, commerce and in science. Thus the stalks of *Laminaria* are used in surgery, and a Japanese seaweed supplies the source of agar-agar, the medium so much used in cultivating bacteria in the laboratory.

"THE BOTANICAL MAGAZINE."—The issue for April contains illustrations and descriptions of the following plants:—

HIBISCUS WAIMEAE, tab. 8,547.—Those who cultivate the beautiful *Hibiscus Rosa-sinensis* and its allies will appreciate this large-flowered species, with its conspicuous, pink-coloured column of anthers, some 5 or 6 inches long, and broad white petals. The species is a native of the Hawaiian Archipelago and has been grown under the name of *H. Arnottianus*, which has been given to three distinct plants. *H. Waimeae* forms a tree of 25 feet high; but specimens in the Mexican house at Kew have flowered when 8 feet in height, so that the species may be suitable for cultivation indoors if growth is

restricted by pruning. The requirements as to soil and temperature are the same as those for *H. Rosa-sinensis*.

GLADIOLUS MASONIORUM, tab. 8,548.—This beautiful, creamy-yellow flowered *Gladiolus* promises to provide a valuable plant. The species was discovered in Tembuland in 1910 by Canon G. E. MASON and his sister, hence the specific name. Specimens at Kew have withstood 11 degrees of frost, but it is not certain whether the plant is perfectly hardy in this country, as the situation at Kew was a very sheltered one. However, it is the practice of many to lift *Gladioli* at the end of the season, and the question of its hardiness need not stand in the way of its use as a summer-flowering plant for the pleasure garden.

BERBERIS PRATTII, tab. 8,549.—This new Chinese species has, like the new *B. Wilsonae*, very attractive berries and will be valued for the shrubbery, as the flowers are more beautiful than most of the Chinese species, whilst the bunches of salmon-red fruits will provide pleasing colouring in September, when the gardens are beginning to lose something of their summer beauty. The plant forms a shrub some 6 to 10 feet high and is perfectly hardy.

OLEARIA SEMIDENTATA, tab. 8,550.—This species is very closely allied to *O. chathamica*, figured in *Gardeners' Chronicle*, May 31, 1913, p. 363. The flower-heads are solitary and measure about 2 inches across; the ray florets are purple, being white on the reverse side. The two species grow intermixed in the Chatham Islands, and Dr. L. COCKAYNE observed wild plants of distinct appearances, which were probably hybrids between the two. It is not certain whether either of these *Olearias* would survive the cold of our winters, but *O. chathamica* has flowered out-of-doors in the Rev. A. T. BOSCAWEN'S garden at Ludgvan.

EPIDENDRON PROFUSUM, tab. 8,551.—This densely-flowered species has been confused with *E. ambiguum*, but it has a more dense panicle, shorter and broader sepals and petals, and does not possess the strongly crispate margin in the lip characteristic of *E. ambiguum*. The flowers are very fragrant, of pale yellowish-green colour, and measure 1½ inches across.

PUBLICATIONS RECEIVED.—*Annual Report of the Rothamsted Experimental Station, Harpenden, for 1913*. Secretary, Mr. G. T. DUNKLEY, Rothamsted Experimental Station, Harpenden.—*Successful Gardens for Every Amateur, and Economical Fertilisers for the Garden*. The Chilean Nitrate Committee, Friars House, New Broad Street, London.—*Bulletin du Jardin Botanique de l'Etat a Bruxelles*. Vol. IV.; and *Bulletin de la Societe Royale de Botanique de Belgique*. Tome LII. (Bruxelles: Jardin Botanique de l'Etat.)

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

WINTER-FLOWERING STOCKS.—In your issue of April 4 we read with much interest a note on winter-flowering Stocks, from the pen of Mr. Alexander Reid, of Cheswardine Hall Gardens, in which he states that, in his opinion, the following are the best varieties to grow:—Beauty of Nice (mauve and salmon-pink), Riviera Market (white and rose) and All the Year Round. It may interest your readers to know that we had the pleasure of introducing All the Year Round Stock in 1897 and Riviera Market (white and rose) in 1905, while in 1909 and 1912 we added further varieties to the Beauty of Nice section. Mr. Reid mentions that he was successful in obtaining from 70 to 80 per cent. double flowers, and we may add that in our experimental grounds at Reading the All the Year Round variety has consistently given over 90 per cent. of doubles. *Sutton and Sons, Reading.*

RAINFALL.—The amount of rainfall at my station is much less than in the South. I give you my readings for a comparison:—Year 1914.

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 21.—A meeting of the committees was held in the Vincent Square Hall, Westminster, on Tuesday last, the third meeting and exhibition in three consecutive weeks. The occasion was also the annual exhibition of the National Auricula and Primula Society, a report of which is given on p. 290. The outstanding feature of the show was a collection of 200 varieties of Hippeastrums from Sir Geo. HOLFORD's collection at Westonbirt, the exhibit being awarded a Gold Flora Medal. The Floral Committee recommended seven Awards of Merit to new plants.

The Orchid Committee awarded ten Medals to

Chas. E. Pearson, John Dickson, C. R. Fielder, J. W. Moorman, Wm. Howe, W. H. Page, J. Jennings, Jas. Hudson, T. Stevenson, Geo. Gordon, R. C. Notcutt, A. A. Dorrien-Smith, W. G. Baker, W. A. Bilney, F. W. Horney, Geo. Paul, E. H. Jenkins, W. P. Thomson, and R. Hooper Pearson.

AWARDS OF MERIT.

Campanula cenisia alba.—A pure white form of a charming little Alpine plant: The unopened buds spread prostrate on inch-long stems to be held erect as they open above small rosettes of grey-green ovate minutely-downy leaves. The corolla is an open cup with the lobes cut deeply to within a third of the centre. (Shown by Messrs. R. TUCKER AND SONS.)

Arabis aubrietoides Trevor Seedling.—This is the brightest coloured form that we know of

—January, 112 tons to the acre, or 1.12 inch; rain on 14 days. February, 89 tons to the acre, .89 inch; rain on 18 days. March, 189 tons to the acre, 1.89 inch; rain 22 days—or less than 4 inches in three months. Ernest Horsley, Langford Hall Gardens, Newark-on-Trent.

GARDENERS AND THE B.G.A.—I am instructed by my branch to forward you the enclosed resolution, and to ask you to be good enough to give it publicity:—"The London Branch of the B.G.A. desires to express its strong disapproval of the statements of Mr. T. Smith on p. 224, regarding his opinion of the type of man the B.G.A. would consist of. One would associate any remarks by Mr. T. Smith as being more or less up to date, but if this truly represents his views at the present moment he is woefully behind the times. A single glance at the B.G.A. list of members would show Mr. Smith that if he wishes to remain with the cream of the profession he will quickly have to join the body of men who are quietly but none the less effectively improving the conditions under which gardeners in the past have been labouring." Wm. H. North, Secretary, London Branch of the B.G.A.

OPENINGS FOR EMPLOYMENT IN THE NURSERY TRADE.—If favourable chances are so few for young men in private gardens endeavouring to reach the top of the ladder, as the recent correspondence would go to show, why do not some of them turn to the trade side of the profession? There are many good openings and capable men are scarce. I have advertised in three trade papers and in other mediums, but cannot obtain a good improver or grower, and the wages offered in the latter case were quite equal to those many head gardeners receive. The majority of the men out at the present time seem to just want employment for a few months and then to move. I am speaking from my own experience. No doubt others will have had the same trouble in obtaining suitable men. F. Smith, Uxley Nurseries, Lincolnshire.

MISTLETO ON THE COMMON HAZEL.—Replying to your correspondent, Mr. W. Crump, in the issue of April 4 (see pp. 240, 272), I have to say that in the *Quarterly Journal of Forestry* for January of this year, p. 21, there is a record of Mistletoe occurring on the Hazel at Cliveden, Buckinghamshire. William Somerville, School of Rural Economy, University of Oxford.

ISLE OF WIGHT BEE DISEASE.—This disease, which has wrought so much havoc among the bees of this country, appears to affect the bees of different countries to very different degrees. Thus it is said that the bees of Holland, although not entirely immune, take the disease, when they contract it at all, in a mild form. Advantage is being taken of this fact by Mr J. B. Mason and another apiarist, who, according to a report in the *Times*, are importing 500 colonies of Dutch bees into this country. It is hoped that the imported bees may retain their relative immunity and confer it on their offspring. The attempt is well worth making, but I am inclined to think that it will have a better chance of success if the experiment be carried out along somewhat rigid lines. It is to be observed, for example, that in the only cases in which inheritance of disease resistance has been worked out thoroughly, the result of crossing an immune with a susceptible organism is that the offspring of the first generation are susceptible. Should this prove to be the case in the present instance there is little prospect of the experiment being carried to a successful issue, for susceptibility is likely to mean that the disease will attack and prove mortal to the cross-bred Dutch and British bees. Wherefore every attempt should be made to secure that some at least of the first generation of the cross shall escape this fate. If they do, and if they can be used to fertilise queens of the Dutch race, there is a prospect that some of the descendants will be immune. It is to be hoped also that, side by side with this experiment, observations will be made on the degree of immunity of the several imported colonies. It may not be possible to obtain statistics of mortality in the 500 hives, but it will not be difficult to discover which, if any, show the highest degree of resistance. A. B.

FIG. 127.—CLEMATIS MONTANA SUPERBA: FLOWERS WHITE.
(See Awards of Merit.)

collections and recommended one First-class Certificate and one Award of Merit to novelties.

Exhibits before the Narcissus Committee were fewer than at the two previous meetings, but four varieties of Narcissus and three of Tulips were granted Awards of Merit.

Only one exhibit was forthcoming in the fruit and vegetable section, and no novelties were submitted for award.

At the 3 o'clock meeting in the Lecture Room the Rev. Professor, GEO. HENSLOW delivered an address on "The Probable Origin of Existing Flowering Plants."

Floral Committee.

Present: H. B. May, Esq. (chairman), Messrs. Chas. T. Drury, C. Blick, C. E. Shea, H. J. Jones, Arthur Turner, John Green, C. Dixon,

this "pink" Arabis, of which the type itself deserves to be much better known. The flowers are bright mauve (shade 1 of the reddish-violet of the *Répertoire des Couleurs*). The habit is neat, much resembling that of the common single white Arabis, but smaller and neater, the greyish leaves being about an inch in length by 1/4 in. in breadth, and the lower ones on long stalks. The flowers are half an inch in diameter, and the stamens exerted. (Shown by Mrs. LLOYD EDWARDS.)

Clematis montana superba (see fig. 127).—This variety differs from the type in its much larger flowers, the largest of which exceed three inches in diameter. There are only four perianth segments, which are borne in the form of a cross, and the variety seems as profuse in flowering as

the type. (Shown by Messrs. JACKMAN AND SONS.)

Pyrus Malus floribunda purpurea.—This is one of the most distinct of the flowering Crabs, on account of its bronzed foliage, and its purplish rose flowers, which are of such a depth of colour that the open petals hardly differ from the common buds, and the general effect is therefore more of a self colour than in the better-known varieties. The flowers have more substance and size than those of *atrosanguinea*, which is perhaps nearest to it in colour. A very distinct feature is the bronze foliage and the purple young wood, given by the purple sap which is at once seen in a cross section of a branch. In this respect it resembles *P. Niedzwetzkyana*, but that variety flowers much less freely. (Shown by Mr. R. C. NOTCUTT.)

Antirrhinum Nelrose.—From the large number of florists' Snapdragons grown by Americans for their value as cut flowers, Mr. Wells in his last visit to the United States singled out this variety as the most distinct and pleasing. It is perpetual flowering, makes yard-long growths which branch freely, and the flower-colour may be described as a pleasing shade of rose-pink, or more accurately as shade 1 of the lilac-rose of the *Répertoire des Couleurs*. Good spikes of it were shown in proof of its freedom, and it is said to be an extraordinarily vigorous doer. (Shown by Messrs. W. WELLS AND SON.)

Polyanthus Orange King.—This variety received the Award for its fine colour, a golden orange petal with a rich coppery orange reverse. It seemed uniformly six-petaled, and the segments were broad and overlapping, incurving slightly at the edges to give a hint of the darker colour of the reverse. (Shown by Mrs. ELLIS, Lincoln.)

Hydrangea Lillie Mouillière.—A large-flowered variety of a very beautiful rose-pink colour a little paler towards the margin. The stamens are pale-blue, and their development introduces a shade which to some is displeasing, but the general colouring of the truss is unusually rich and handsome. (Shown by Messrs. LOW AND CO.)

GENERAL EXHIBITS.

A magnificent collection of *Hippeastrums* (*Amaryllis*) was shown by Lieut.-Col. Sir GEORGE HOLFORD, Westonbirt, Tetbury (gr. Mr. Chapman). There were more than two hundred plants in all, almost as many varieties, and all had been raised at Westonbirt. Most of the specimens had two and some even three inflorescences, four blooms on a spike being common. The pick of the crimson sorts were *Macbeth*, *The Doge*, *Robin Hood*, *Rustan*, *Red Knight*, *Phoebus*, *Vulcan* and *Brian Boru*; fine rose or pink-coloured flowers were seen in *Morning Glow*, *Cardinal Wolsey*, *Paragon*, *Boreas*, *Incretia* and *Rose Queen*; shades of orange and scarlet were represented by such varieties as *Shelley*, *Firelight*, *Hilary*, *Lord Dalhousie* and *Gereant*; whilst of whites *Bridesmaid*, *Snowdrift*, *The Moon*, *Houri*, *Lapwing* and *Winter Queen* were all of outstanding merit. The pick of the collection was *Cardinal York*, the perfectly-shaped blooms being rose-madder in colour. (Gold Flora Medal.)

Messrs. SUTTON AND SONS, Reading, showed a strain of greenhouse *Cinerarias* as a flat group, with *Adiantum* Ferns separating the various colours. At the back was a broad band of plants with flowers of pink shades, and in front were clumps of blue, pale pink, rose, white, crimson and other varieties. (Silver Banksian Medal.)

Messrs. ED. WEBB AND SONS, Stourbridge, were awarded a Silver Banksian Medal for a floor group of greenhouse *Cinerarias*. The plants were well grown and splendidly flowered.

R. MCCONNELL, Esq., Greystones, Bromley (gr. Mr. H. Page), showed large, bushy plants of a blue-flowered variety of *Star Cineraria*. (Silver Banksian Medal.)

Messrs. JAMES VEITCH AND SONS, LTD., Chelsea, showed well-flowered *Azaleas*, *Rhododendron Veitchianum*, *R. fragrantissimum* and *Hippeastrums*, for which a Silver Flora Medal was awarded. Much the best *Hippeastrum* was the beautiful orange-scarlet coloured *Homer*.

Messrs. H. B. MAY AND SONS, Edmonton, were awarded a Silver Flora Medal for *Roses*, *Clematis*, *Verbenas*, *Marguerite Mrs. F. Sander*, *Hydrangeas*, *Pansies* and *Violas*.

Messrs. W. CUTBUSH AND SON, Highgate, showed *Roses*, *Carnations* and *Alpines*, for which a Silver Flora Medal was awarded. The *Roses* included excellent plants in pots of the dwarf polyantha varieties *Jessie*, *Baby Tausendschön*, *White Pet* and *Mrs. W. Cutbush*. There were also taller specimens of *Excelsa* (known as *Red Dorothy Perkins*) and the new *Mme. Turbat*, with pink flowers like those of *Tausendschön*.

Mr. R. C. NOTCUTT, Woodbridge, showed shrubs in flower, including beautiful double-flowered *Cherries* from Japan, *Amelanchier canadensis*, *Spiraea arguta*, *Prunus triloba* and double-flowered *Peaches*.

Messrs. WILLS AND SEGAR, South Kensington, exhibited *Heaths*, *Mignonette*, and, in the centre, a bank of blue-flowered *Hydrangeas*. (Silver Banksian Medal.)

Messrs. STUART LOW AND CO., Bush Hill Park, Enfield, arranged a pretty bank of flowering plants, consisting of the *Bottle Brush*, *Meterosideros floribunda*, species of *Acacia*, *Boronias* in variety, *Daphne Cneorum* and *Eriostemon nerifolia*. This firm also showed varieties of *Perpetual-flowering Carnations*. (Silver Flora Medal.)

Messrs. J. CHEAL AND SONS, Crawley, exhibited an imposing group of flowering trees and shrubs relieved with ornamental-leaved *Maples*.

Mr. L. R. RUSSELL, Richmond, showed Japanese *Maples* and flowering sprays of *Clanthus puniceus*.

Mr. CHAS. TURNER, Slough, showed standard *Lilacs* with a frontage of *Hydrangea hortensis* in pots. (Silver Banksian Medal.)

Messrs. R. GILL AND SONS, Falmouth, again showed trusses of *Rhododendrons*, the handsome *R. Falconeri* being prominent in the collection. They also exhibited the scarlet-flowered *Embothrium coccineum* and *Myosotidium nobile*.

Col. LOCKWOOD, M.P., Bishop's Hall, Romford (gr. Mr. G. Craddock), again showed plants of *Gardenias* trained as standards, this time in association with *Schizanthus*. (Bronze Flora Medal.)

Messrs. B. R. CANT AND SONS, Colchester, staged beautifully fresh *Roses*, with fine plants of pillar varieties at the back, *Tausendschön* and *American Pillar* being especially good. (Silver Flora Medal.)

Messrs. ALLWOOD BROS., Wivelsfield, Haywards Heath, showed vases of *Carnations*, for which a Silver Banksian Medal was awarded. Their novelties, *Wivelsfield Wonder* and *Wivelsfield White*, were well displayed.

Carnations were also exhibited by Mr. C. ENGELMANN, Saffron Walden (Silver Banksian Medal), and Mr. H. BURNETT, Guernsey. (Silver Banksian Medal.)

Mr. PHILIP LADDS, Swaunley, Kent, arranged a floor group of *Hydrangeas*, *Heliotropiums* and *Ericas*.

Messrs. H. CANNELL AND SONS, Eynsford, Kent, exhibited varieties of zonal-leaved *Pelargoniums* in a collection of other flowering plants.

Zonal *Pelargoniums* were also shown by Messrs. A. H. COLE, LTD., Swanley; Messrs. H. J. JONES, LTD., Hither Green, Lewisham; and Mr. VINCENT SLADE, Taunton.

Messrs. CARTER, PAGE AND CO., London Wall, showed *Violas* and hardy annuals.

Messrs. PIPER AND SONS, Bayswater, again surpassed all other exhibits of rock-gardens in their display, which was staged in the same place as at the last two meetings. (Silver Flora Medal.)

Messrs. R. WALLACE AND CO., Colchester, exhibited an interesting collection of hardy flowers, principally of bulbous kinds. There were numerous species of *Fritillaria*, *Tulipa Greigii*, *T. G. aurea*, the new *T. stellata*, *Iris Pumila crosses* and *Primula Juliae*.

Mr. JAMES BOX, Haywards Heath, arranged, in the same corner as at the last two meetings, a rockery, and planted it with a great variety of subjects. (Silver Flora Medal.)

Messrs. WATERER, SONS, AND CRISP, LTD., Twyford, planted a rockery with *Alpines* and dwarf shrubs. They showed a compact, free-flowering variety of *Phlox subulata* named *B. E. C. Chambers*; a batch of the manve-flowered *Primula frondosa* and red-flowered *Saxifragas*, including *S. bathoniensis*. (Silver Banksian Medal.)

Messrs. BARR AND SONS, Covent Garden, exhibited a rockery planted with bulbous flowers and *Alpines*.

Messrs. BUNYARD AND CO., LTD., Maidstone, made a feature with varieties of *Primula Sieboldii* in their rock-garden exhibit, for which a Bronze Banksian Medal was awarded.

Messrs. R. TUCKER AND SONS, Oxford, were awarded a Bronze Flora Medal for a rock-garden, prominent plants being *Helichrysum bellidioides*, *Campanula cenisia* and its white form, which received an Award of Merit.

The Misses HOPKINS, Shepperton, exhibited a rockery planted with seasonable *Alpines* and hardy flowers. (Bronze Banksian Medal.)

Messrs. T. S. WARE, LTD., Feltham, were awarded a Silver Banksian Medal for hardy flowers. The pale blue *Anemone Robinsonianum* was charming, and there were many beautiful varieties of *Aubrietia*.

The feature in the exhibit of hardy flowers shown by the BURTON HARDY PLANT NURSERY was a mass of the pink-flowered *Daphne Cneorum* major.

Mr. G. REUTHE, Keston, Kent, exhibited *Rhododendrons* and *Alpines*, for which a Silver Banksian Medal was awarded. There were splendid pans of *Narcissus bulbocodium conspicuum*; the tiny white-flowered *Pyxidanthera barbulate*, and a new *Rhododendron*—*R. Searisae*, in the way of *R. yunnanense*, but with a bolder truss.

Messrs. THOMPSON AND CHARMAN, Bushey, Hertfordshire, exhibited hardy flowers, in which were observed fine specimens of *Iris Susiana* and the pretty pink-flowered *Phlox Vivid*.

Messrs. J. AND A. CLARK, LTD., Dover, exhibited a large batch of *Polyanthus Cloth of Gold* in a collection of hardy flowers. (Bronze Flora Medal.)

Mr. MAURICE PRICHARD, Christchurch, was awarded a Silver Banksian Medal for *Alpines* arranged on a rockery.

Mrs. E. LLOYD EDWARDS, Bryn Oerog, near Llangollen, was the exhibitor of seedling *Saxifragas* and *Viola gracilis*, which were awarded a Silver Banksian Medal.

Hardy flowers were also exhibited by Messrs. WHITELEGG AND PAGE, Chislehurst; THE GUILDFORD HARDY PLANT NURSERY; Messrs. PHILLIPS AND TAYLOR, Bracknell (Silver Banksian Medal), Mr. REGINALD PRICHARD, West Moors, Wimborne (Bronze Flora Medal); and Messrs. G. JACKMAN AND SON, Woking (Bronze Flora Medal).

Mr. GEO. KERSWILL, Exeter, showed bunches of the beautiful *Gentiana acaulis* and varieties of *Saxifraga*.

Messrs. REAMSBOTTOM AND CO., Geashill, Ireland, again showed their showy *St Brigid Anemones*, for which a Bronze Banksian Medal was awarded.

Mr. JOHN CROOK, Camberley, Surrey, exhibited a strain of *Polyanthuses*, which included many beautiful bronze and red-flowered varieties.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair, and Messrs. Jas. O'Brien (hon. secretary), W. Bolton, Gurney Wilson, De B. Crawshaw, W. H. White, A. Dye, W. H. Hatcher, H. G. Alexander, J. Cypher, J. Charlesworth, W. Cobb, F. M. Ogilvie, F. J. Hanbury, T. Armstrong, R. G. Thwaites, Stuart Low, R. A. Rolfe, S. W. Flory and Sir Jeremiah Colman, Bart.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum Mirabeau var. Mastiff (*mirum* × *Lambcauanum*) (see fig. 123), from J. AND A. McBEAN, Cooksbridge. This is a grand flower, one of the largest and darkest in colour, the massive blooms having a clear white ground so heavily blotched with deep maroon-purple that the white only shows at the margins and slightly between the large blotches. *O. crispum*, *O. Pescatorei*, *O. luteo-purpureum* and *O. Harryanum* are all in its composition, and the result is highly satisfactory.

AWARD OF MERIT.

Oncidioid Cooksoniae Grenadier (*C. Noezliana* × *O. macranthum hastiferum*), from PANTIA RALLI, Esq., Ashted Park, Surrey. *Grenadier* is the darkest of the four varieties which have

received Awards at the Royal Horticultural Society. Flowers circular in outline, equal in size to *O. macranthum*, bright scarlet, with a ruby-red tint.

CULTURAL COMMENDATION.

To Mr. BALMFORTH (gr. to F. Menteith Ogilvie, Esq., The Shrubbery, Oxford) for a fine specimen of the handsome *Odontioda* Mrs. F. M. Ogilvie (F. C. C., May 22, 1912), now bearing a branched spike of 60 beautiful flowers.

To Mr. BALMFORTH for a grand specimen of the deep red *Odontioda* Diana, with several spikes, bearing together 177 blooms.

To Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, for a gigantic plant of *Coelogyne pandurata* Orchidhurst variety, grown from a single bulb. The spike, which was 3 feet in length, bore thirteen pale-green flowers, with black markings on the lip each at the widest expansion 6 inches across.

To Messrs. SANDER AND SONS, St. Albans, for a large and finely-flowered specimen of *Phaius Sanderianus*, with several stout spikes over 5 feet in height.

GENERAL EXHIBITS.

Lieut.-Col. SIR GEO. L. HOLFORD, K.C.V.O. (gr. Mr. H. G. Alexander), sent *Odontoglossum crispum* Iolanthe, a charming pure white form with violet-coloured spots in the centre of the sepals; the finely-grown plant bore a spike of ten blooms; *Sophrro-Cattleya Thwaitesii* (S. grandiflora × C. Mendelii), which secured a First-class Certificate in 1909, and is still one of the best *Sophrro-Cattleyas*, its bright dark-red colour and yellow lip with ruby margin and front being very attractive.

F. MENTEITH OGILVIE, Esq., Oxford (gr. Mr. Balmforth), staged a collection of thirteen superbly grown *Odontiodas* giving a mass of bright-red flowers, with *Brasso-Laelio Cattleya Veitchii* of fine colour, and for which a Silver Flora Medal was awarded.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), staged a very interesting group of *Odontoglossums*, *Odontiodas* and *Cypripediums*. Specially noteworthy were *Chondrorhyncha Chestertonii*, varieties of *Miltonia vexillaria*, *Bulbophyllum galbinum* and other *Bulbophyllums*; some fine *Cattleya Schröderae*, *Brasso-Cattleya William Pitt*, a good selection of *Laelio-Cattleyas*, and seedling *Odontoglossums*. (Silver Flora Medal.)

Messrs. STUART LOW AND Co., Jarvisbrook, Sussex, had a very fine group specially rich in showy *Dendrobiums*, which included the blue *Victoria Regina*, white forms of *crystallinum* and noble, *thyrsiflorum*, *Devonianum*, *Jamesianum*, *suavissimum*, *Wardianum* and hybrids. With them were good *Odontoglossums*, *Brasso-Cattleyas*, *Renanthera Imschootiana*, *Phalaenopsis Rimestadiana*, etc. (Silver Flora Medal.)

Messrs. J. AND A. McBEAN, Cooksbridge, staged a group remarkable for the fine growth and good flowering of forms of *Cattleya Mossiae*, C. Mendelii, C. Schröderae, the enormous size of the pseudo-bulbs being evident throughout. *Cattleya Lawrenceana* bore a spike of nine flowers; *Laelio-Cattleya* G. S. Ball, and two good L.-C. Ganymede, some good *Odontoglossums*, *Odontiodas* and *Miltonias* were also noted. (Silver Flora Medal.)

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. Collier), showed the F. C. C. variety of *Odontioda Vuylstekeae* Lady Colman of brilliant colour; *Dendrobium Brymerianum* Gatton Park variety, *D. Nestor*, two fine forms of *Coelogyne Lawrenceana*, and the singular *Luisia Cantharis*.

Messrs. CHARLESWORTH AND Co., Haywards Heath, showed a select group in which were *Odontoglossum percultum*, of a fine violet colour; *O. Pescatorei Charlesworthii*, large and prettily blotched with purple; *Miltonia vexillaria* Empress Augusta Victoria, with four spikes of fine rose-coloured flowers; *Sophrro-Laelio-Cattleya heatonensis*, and S.-L.-C. Niobe, *Laelio-Cattleyas*, etc. A pretty novelty in this group was *Odontioda Elsie* (*Cochlioda Noezliana* × *Odontioda Charlesworthii*), a good broad red flower.

R. G. THWAITES, Esq., Chessington, Streatham, showed a small group of interesting hybrids, including *Odontiodas* and *Dendrobiums*.

Dendrobium Frederickii (*fimbriatum* × *Thwaitesiae*) was a singular hybrid, with a raceme of yellow flowers; *Odontoglossum Edna* (*Rossii rubescens* × *ardentissimum*), a pretty lilac flower with dark spotting; and *Brasso-Cattleya* Mrs. J. Leemann. (Silver Banksian Medal.)

Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, showed a good group, principally hybrids, the *Brasso-Cattleya Digbyano-Mossiae splendens* and other hybrids of B. Digbyana being prominent; *Miltonia St. Andre*, *Cypripedium Venus Orchidhurst* variety; a good blotched *Odontoglossum crispum* with a spike of thirty-three flowers; and other showy *Odontoglossums*, *Coelogyne pandurata* and *Bulbophyllum barbigerum*. (Silver Banksian Medal.)

Messrs. FLORY AND BLACK, Slough, staged an attractive group, the setting of which was of good *Cattleya-Schröderae* and *Laelio-Cattleyas*, among which L.-C. Violetta, L.-C. Medina,

delii, *Oncidium Marshallianum*, *O. concolor*, *Miltonia Bleuana splendens*, *Dendrobium Jamesianum*, *D. fimbriatum oculatum*, *Masdevallia Shuttleworthii*, *M. Heathii*, *Oncidium concolor*, etc. (Silver Banksian Medal.)

Messrs. W. BAYLOR HARTLAND, Cork, showed a selection of *Cattleyas*, *Cymbidiums*, *Cypripediums* and *Brasso-Cattleyas*. (Bronze Banksian Medal.)

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), sent good examples of *Odontoglossum harvengtense* (*crispum* × *triumphans*), *O. Titania* (*Queen Alexandra* × *crispum*), and *O. Leonidas* (*Hallio-crispum* × *triumphans*).

Messrs. HASSALL AND Co., Southgate, showed a very fine white *Cattleya Dusseldorfei* Undine, the front of the lip being unusually broad and well developed.

C. KIRCH, Esq., Uplands Road, Hornsey, showed a very good specimen of *Coelogyne pandurata*.

FIG. 128.—*ODONTOGLOSSUM MIRABEAU*, VAR. *MASTIFF*; PETALS AND SEPALS COLOURED MAROON-PURPLE, WITH WHITE MARGINS.

(R.H.S. Award of Merit on Tuesday last; see p. 288.)

L.-C. Myra, and some unnamed hybrids were noted. *Brasso-Cattleya Madame Chas. Maron* × C. Mendelii was an attractive white flower, with fringed lip having a rose-coloured blotch; a very large-flowered *Odontoglossum Pescatorei*, *Coelogyne Lawrenceana*, *Masdevallia Bocking Hybrid*, *Epidendrum aurantiacum*, *Cattleya intermedia alba*, *Laelia anceps alba*, and the rare *Disa polygonoides*. (Silver Banksian Medal.)

Messrs. SANDER AND SONS, St. Albans, had an extensive group in which were many showy *Dendrobiums*. *D. densiflorum superbum* was probably the finest yet shown. Some new hybrids, *Laelio-Cattleyas*, *Vanda suavis* with two spikes, *Acanthophippium sylhetense*, *Masdevallia Schlimii* and other *Masdevallias*, *Vanda coerulea*, the white *Trichopilia Hennisii*, *T. suavis*, *Bifrenaria Harrisoniae pubigera* and other species were also well shown. (Silver Banksian Medal.)

Messrs. J. CYPHER AND SONS, Cheltenham, arranged a group of *Cattleya Schröderae*, C. Men-

Narcissus and Tulip Committee.

Present: E. H. Bowles, Esq. (in the chair), Miss E. Willmott, Rev. Joseph Jacobs, Messrs. J. T. Bennett-Poe, W. F. M. Copeland, A. D. Hall, J. Duncan Pearson, J. S. Dickins, P. Rudolph Barr, Charles T. Digby, W. A. Milner, R. W. Wallace, Harold A. Denison, C. Lemesle Adams, Jan de Graaff, and Chas. H. Curtis (hon. sec.).

AWARDS OF MERIT.

Narcissus Horace (for the garden and cutting).—One of the best of the recent Poeticus varieties, which possesses in a marked degree the desired round, glistening perianth and entirely scarlet corona.

N. Chopatira (for the garden).—A very large, rich yellow Trumpet Daffodil, having a broad, overlapping perianth and very long trumpet.

N. Boduin (for the garden and cutting).—A most beautiful *Incomparabilis* variety; the over-

lapping perianth segments are white, and the small orange-coloured corona is attractively tipped with a darker shade of the same. This and the foregoing varieties were shown by Messrs. BARR AND SONS.

Narcissus Josine (for the garden).—A trumpet variety of the type of Mme. de Graaff, the pale primrose coloured trumpet being set off by a white perianth. Shown by Messrs. E. H. KRE-LAGE AND SON, Haarlem, Holland.

Tulip Pelican.—A large, handsome variety of perfect form. The deep rose colour is relieved and enhanced by the lighter tips of the perianth segments.

Tulip Ibis.—A pure white Tulip of large size and perfect shape. Both Tulips were shown by Messrs. VAN WAVEREN AND KRULFF, Sassenheim, Holland.

Tulipa stellata.—A dainty species of much the general appearance of *T. Clusiana*, but which has more obtuse perianth segments. The outer segments are flushed with chestnut-red, which, as the three inner segments are white, give the flowers a striped appearance. The plants shown were about nine inches high, and appear adapted for cultivation either in small pots or in the rock garden. This species was introduced from the Himalayas in 1827, and is figured in *Bot. Mag.* tab. 2,672. Shown by Messrs. BARR AND SONS.

GENERAL EXHIBITS.

MESSRS. BARR AND SONS, Covent Garden, London, included a large number of mid-season Poeticus Narcissi in their exhibit. Such varieties as *Horace*, *Ibis*, *Cassandra*, *The Bride*, *Ruskin*, *Socrates* and *Herrick* were all noteworthy for the purity of their perianth segments and the brightness of the small, compact coronas. Of the Trumpet Daffodils Earl Goodwin, a pale primrose and golden yellow bicolor, and *Etheldreda*, a pale lemon self, and both bold, showy flowers, were admirable; whilst Major Spurrell, a *Barrii* bloom, possessing a clear white perianth and very bright corona, was conspicuous. (Silver-gilt Flora Medal.)

Mr. C. BOURNE, Simpson, Bletchley, arranged a smaller collection of Daffodils in the annexe, where we noticed *Queen of the North* (Leedsii), *Whitewell* (Incomparabilis), *Incognita*, and *Imperialist* (Barrii), and Rev. Chas. Digby (Triandrus) in splendid form. At one end of the Daffodils a collection of Tulips included large blooms of *The Bishop*, *The Fawn*, *Glow* and *Mrs. Farncombe Sanders*. (Silver Flora Medal.)

MESSRS. W. B. HARTLAND AND SONS, Ardcairn, Ballintemple, Cork, had a good display in which *Epic* (Poeticus), *Rosa Bedford* (Barrii), *Maud West* and *Evangeline* (Leedsii) were very prominent.

Mr. ALFRED DAWKINS, King's Road, Chelsea, displayed a large number of valuable Narcissi, chiefly of *Barrii* and *Leedsii* varieties.

Fruit and Vegetable Committee.

Present: J. Cheal, Esq. (in the chair), Messrs. J. Willard, Edwin Beckett, John Harrison, G. Reynolds, P. C. M. Veitch, H. H. Williams, Owen Thomas, C. G. A. Nix and Geo. Kelf.

The Marquis of SALISBURY, Hatfield House, Hertfordshire (gr. Mr. H. Prime), showed fruiting plants and gathered berries of Strawberries, for which a Silver-gilt Knightian Medal was awarded. The fruits were large in size and well coloured. The varieties were *King George V.*, *Royal Sovereign*, *Utility* and *The Queen*.

NATIONAL SWEET PEA.

APRIL 20.—A special general meeting of this Society was held on Monday last in the Hotel Windsor, Westminster, to consider the alteration of rules as proposed at the annual meeting on October 20, 1913. There were about forty present, and the chair was taken by Mr. F. W. Harvey.

The following were the proposed new rules:—

ELECTION OF FLORAL COMMITTEE.

(8) The Floral Committee shall be elected annually from the Members of the Society by the Members present at the Annual General Meeting, by ballot. Written nominations from Members must be sent to the Secretary of the Society at least seven days before the Annual General Meeting.

(9) The Floral Committee shall consist of sixteen (16) Members, irrespective of whether they be amateurs or traders, but there shall not be less than six (6) amateurs. The complete Floral Committee shall serve as an Advisory Committee. The awards shall be made by an

Awards Sub-Committee of not more than nine (9) and not fewer than six (6) Members, who shall be Members of the Floral Committee, shall be amateurs, and shall have no interest in anything at the Trials.

(10) The Floral Committee shall elect one of its own Members, being an amateur and having no interest in anything at the Trials, annually as its Chairman.

(11) The Floral Committee shall visit the Society's Trials once or twice annually, as may be deemed necessary. The visits to be made before the visit of the general body of Members.

(12) No Member of the Society shall visit the Society's Trials until the Floral Committee has completed its task, unless instructed or authorised to do so by the General Committee.

(13) The Secretary of the Society, after consultation with the Trials Superintendents, shall convene the Floral Committee, and shall give five (5) clear days' notice to the Members.

(14) The Awards of Merit or First Class Certificates shall be decided on show of hands by a bare majority of the Awards Sub-Committee, but the award of a Medal shall be by the unanimous vote of the Awards Sub-Committee. The variety which at the time appears worthy of the distinction shall be finally awarded the Medal the following season at or before the London Exhibition (if possible), if the variety has kept true to type and colour.

(15) A numerical register of the varieties at the Society's Trials shall be prepared for the use of the Floral Committee, and it shall be the duty of the Chairman, or the Secretary, to enter the remarks of the Members of his Committee therein.

(16) The Floral Committee shall prepare a list of Too-much-alike varieties, irrespective of whether these have, or have not, been grown at the Trials.

(17) The Awards Sub-Committee, after consultation with the Floral Committee, shall constitute a Selection and Nomenclature Committee. It shall indicate the three varieties which it considers the best in each colour class, with their synonyms, and place them in order of merit. It shall settle all questions of nomenclature.

It was agreed, on the proposition of Mr. Thomas Stevenson, seconded by Mr. Brunton, that in the event of any of these new rules or amendments being adopted the same should not become operative until September 1, 1914. This was to enable the rules to become operative in time for nominations to be made before the next annual general meeting.

The chairman then formally moved the adoption of the new rules, and the motion was seconded by Mr. C. H. Curtis.

Mr. S. B. Dicks asked if the rules were to be taken *en bloc*, and the chairman replied that they would be for reasons which would be apparent later.

Mr. Andrew Ireland then proposed as an amendment that the meeting do not adopt any of the proposed new rules. He could never understand why the Committee recommended the alterations, seeing that the existing rules made every necessary provision.

Mr. Dicks saw no reason for altering the rules, which had worked well in the past. He bore evidence to the honour and integrity of the members of the Floral Committee, of which he was formerly a member. He considered the proposals a stab in the back for the members of the trade, and that they implied dishonourable conduct. He had pleasure in supporting Mr. Ireland's amendment, as he considered that the change would not further the best interests of the Society.

Mr. John Green also supported the amendment, and he asked for the opinion of the Committee on the question.

Mr. Baker (Wolverhampton) was in favour of discussing the new rules, as some change was necessary, seeing that the Society had to a great extent lost the confidence of the general public. If the question of awards to novelties were considered it would be found that some varieties that had received awards were not regarded as first-rate, whilst others not awarded were in the front rank. He considered that they could improve the rules and in doing so gain greater public confidence.

The chairman remarked that there was no evidence that the public was displeased, seeing that 101 new members and 18 affiliated societies had joined the Society since last October.

Mr. Brunton, in supporting the amendment, considered that it would be better to bring the matter up at the next general meeting.

Mr. Vernon Hill considered that the whole trouble was due to persons who were disappointed at their varieties not getting awards at the trials. He suggested that the votes of the Floral Committee should be recorded and published.

Mr. E. W. King said he would like to support the amendment, but he thought that if it were carried it would defeat the object for which the meeting was convened.

It was pointed out by the chairman that in that case the resolutions would not be lost, but could be brought up again at the next annual meeting.

On a show of hands the amendment was declared to be carried by 26 votes to 6; and, being put as a substantive motion, was adopted by 23 votes to 5.

NATIONAL AURICULA AND PRIMULA.

(SOUTHERN SECTION.)

APRIL 21.—The thirty-eighth annual show, which was held at Vincent Square, London, in conjunction with the fortnightly meeting of the Royal Horticultural Society, will rank, as regards the quality of the exhibits, as one of the finest ever held in the South of England, but owing to the vagaries of the season the entries were not so numerous as usual. In the esteem of the majority of the visitors, who do not seem to appreciate the "points" of the show and fancy varieties, the Alpine Auriculas were the best. Primroses and Polyanthuses were splendid, but the three *Primula* classes did not induce much competition, although Messrs. PHILLIPS AND TAYLOR exhibited a very attractive collection in Class 26.

Twelve Auriculas, dissimilar.—The premier class was responsible for three exhibits, of which the best was shown by Mr. J. DOUGLAS, Edenside, Great Bookham, whose principal plants were *Pingo* (rich dark maroon), *Favourite* (purple self), *Harrison Weir* (rich crimson self) and *Edenside* (large green edge), which was adjudged the premier show variety; 2nd, Messrs. PHILLIPS AND TAYLOR, Bracknell, Berkshire, whose trusses were a trifle smaller, but bore bright and fresh blooms of good quality; 3rd, Mr. W. M. SHIPMAN.

Six Auriculas, dissimilar.—Mr. DOUGLAS won the first prize in this class with a rather uneven set of plants, but perhaps the excellence of *Favourite* and *Harrison Weir* compensated for this defect; 2nd, Messrs. PHILLIPS AND TAYLOR; 3rd, Mr. W. M. SHIPMAN.

Four Auriculas, dissimilar.—This class was well contested, and Mr. F. W. PRICE, Beckenham, won the chief award with plants which bore the stamp of skilful cultivation; *Harrison Weir*, *Olympus* (large grey edge) and *Mrs. Henwood* (green-edge) were very good. Mr. H. R. TAYLOR, Cheam, was a close second, and his plants of *Heatherbelle* (white-edge) and *Harrison Weir* were very pleasing; 3rd, Mr. W. G. LANGLANDS.

Two Auriculas, dissimilar.—Mr. F. W. PRICE won the 1st prize with moderate examples of *Mrs. Henwood* and *Lancashire Hero*; 2nd, Mr. W. G. LANGLANDS.

In the class for amateurs the best four show Auriculas were staged by Mr. J. L. GIBSON, Belmont, and Mr. Morton's Silver Medal, offered for the best similar exhibit by tyros, was won by Mr. H. W. MASON, Banstead, with a particularly good collection.

Single Specimens.—Mr. J. DOUGLAS, showing *Prince Charming* (green-edge), *George Lightbody* (grey-edge), *Mrs. J. Eighteen* (white-edge) and *Black Eagle* (self), won the first prizes offered for single specimens.

Seedlings, not previously exhibited.—Mr. W. M. SHIPMAN won four first prizes in these classes, his plants of green-edged, white-edged and self (a beautiful royal purple) varieties being especially promising.

ALPINE AURICULAS.

Twenty-four Varieties, dissimilar.—Messrs. PHILLIPS AND TAYLOR showed an exceedingly bright collection of well-grown plants, which bore large, full spikes of bloom and deservedly won the 1st prize. This noteworthy collection was particularly strong in the gold-centre varieties, of which *Her Grace*, *Majestic*, *Sunbeam* and *Charmer* are typical varieties. *Antarctic* and *Phyllis Douglas* (white centre) were also unusually good; 2nd, Mr. W. M. SHIPMAN, Altrincham, who showed a good selection, but inferior in quality.

Twelve Varieties, dissimilar.—This was a particularly strong class. The 1st prize was won by Mr. J. L. GIBSON, Belmont, who staged a magnificent collection, in which *Blue Jay*, *Argus*, *Roxborough* (white centres) and *Golden Dustman*, *Claud Halcro* and *Jacoby* (gold centres) were

especially fine; 2nd, Messrs. PHILLIPS AND TAYLOR, who had good examples of Daphne, Antonio, Phyllis Douglas and a gold-centre seedling; 3rd, Mr. F. M. SHIPMAN.

Six Varieties, dissimilar.—Mr. F. W. PRICE, showing such varieties as Argus, Phyllis Douglas and Golden Douglas, won the 1st prize; 2nd, Mr. J. J. KEEN, Southampton, who had an excellent plant of Argus; 3rd, Mr. J. T. BENNETT-POE.

Four Varieties, dissimilar.—The 1st prize exhibit of Mr. F. W. PRICE was very attractive in the compact trusses of large blooms, Prime Minister and Argus being particularly fine; Mr. J. J. KEEN was a very good 2nd; and Mr. W. G. LANGLANDS 3rd.

Single Specimens.—The best gold-centre plant was Muriel, the best white or cream centre Alpine Auricula, Roxborough; both shown by Mr. DOUGLAS.

Seedlings.—The Silver Medal of the R.H.S. offered for the best four seedling plants of Alpine Auriculas was won by Mr. W. M. SHIPMAN, who showed several pretty seedlings.

Mr. JAS. DOUGLAS, who showed typical specimens, was awarded the 1st prize in the class for twelve fancy Auriculas.

PREMIER PLANTS.

Show.—*Edenside*, by Mr. DOUGLAS.

Alpine.—*Muriel*, by Mr. DOUGLAS.

FIRST-CLASS CERTIFICATES.

Auricula Edenside.—Green-edge show Auricula. A. Mrs. John Eighteen.—White-edge show Auricula. Both shown by Mr. DOUGLAS.

A. *Climax.*—Grey-edge show Auricula. Shown by Messrs. PHILLIPS AND TAYLOR.

A. *Hector.*—Gold-centre Alpine. Shown by Mr. J. J. KEEN.

PRIMROSES AND POLYANTHUSES.

Mr. S. MORTIMER won the 1st prizes for groups of Primroses and of Polyanthuses showing, in both instances, splendid, very floriferous plants; the 2nd prize Polyanthuses, staged by Mr. J. G. BAXTER, were very good, but were overshadowed by the excellence of the 1st prize collection. Mr. W. G. LANGLANDS was awarded the Silver Medal for six pots of Polyanthuses; 2nd, Mrs. ELLIS.

Messrs. COCKER AND SONS, Aberdeen, were awarded the 1st prizes for twelve single Primroses and for six double Primroses with excellent sets of plants. Mr. H. J. BARTLEET, Shooters Hill; showed the best single specimen Primrose, and Mr. S. MORTIMER won the 1st prize for a specimen Polyanthus.

FIRST-CLASS CERTIFICATES.

Primula denticulata superba.—A greatly improved variety, which is more floriferous and more richly coloured than the type. Shown by Messrs. COCKER AND SONS.

Polyanthus Orange King.—A very distinct and beautiful variety; the orange-coloured flowers have bronze reverses and are borne on stout stalks. Shown by Mrs. ELLIS.

Double Primroses, Bon Accord Varieties.—Nine certificates were awarded to Messrs. COCKER AND SONS for different double Primroses, which were of compact and floriferous habit; those named Primrose Prince and Star were pretty.

MEDALS.

The James Douglas Memorial Cup and Medal were awarded to Mr. J. L. GIBSON, who also won the Silver-gilt Aggregate Medal. The Silver Medal offered in the smaller classes was won by Mr. F. W. PRICE.

Exhibits of Auriculas not for competition were made by Messrs. JAMES VEITCH AND SONS, Messrs. PHILLIPS AND TAYLOR, Mr. J. DOUGLAS and Messrs. G. and A. CLARK.

SCOTTISH HORTICULTURAL.

APRIL 7.—The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh on the 7th inst. Mr. King, the president, was in the chair, and there was an attendance of 80 members.

Mr. C. W. B. WRIGHT, of the Edinburgh and East of Scotland College of Agriculture,

delivered a lecture, illustrated by lantern slides, on "The Controlling of Fungous Diseases by Spraying." The lecturer stated that while many fungi live entirely in the interior of the plant, others live on the surface of it, and could, therefore, be controlled by spraying. He dealt only with the latter group, as it was obvious that fungi which lived inside plants could not be controlled by this means. He proceeded to demonstrate how several of the most common fungicides were prepared, and suggested suitable methods of applying them. He laid special emphasis on the fact that the spray should be of a fine, mist-like consistency. He then dealt with three common diseases—American Gooseberry mildew, black scab of Apples, and Celery blight, and he explained how these diseases, which may to a great extent ruin a crop of Gooseberries, Apples or Celery, might be satisfactorily controlled. Great stress was laid throughout the lecture on the necessity for spraying from an economic point of view.

The exhibits included the following:—Rhododendron Grievei, exhibited by Mr. WM. SMALE, Blackford Park Gardens, Edinburgh; Aralia Sieboldii in fruit, exhibited by Mr. JOHN PHILLIPS, Edinburgh; Seedling Myosotis, exhibited by Mr. PETER ROBERTSON, Ancrum; Polyanthus, exhibited by Mr. JAMES W. SCARLETT, Sweethope, Musselburgh; early variety of Rhubarb, exhibited by Mr. GEORGE BALMER, Edinburgh; and Fusarium on tubers of Potato, exhibited by Mr. W. G. PIRIE, Dalhousie Castle, Bonnyrigg.

At the meeting on May 5, Mr. ROBERT FIFE will give a paper, with lantern illustrations, on "Manorial Experiments with Sweet Peas."

KENT, SURREY, AND SUSSEX DAFFODIL

APRIL 17.—The above society, having held its exhibitions previously at Tunbridge Wells, decided upon a change of venue, owing to the lack of public interest at Tunbridge. This year's exhibition, therefore, was held at Horsham, where the Olympia Skating Rink proved an ideal place, from its suitable position, its large space and excellent arrangements for light. Thus visitors found it easy to inspect with comfort the various exhibits.

The most important competitive class was for collections of Daffodils, consisting of six varieties of each of the five divisions—Trumpet, Incomparabilis, Leedsii, Barrii and Poeticus, one vase only of each variety, with three stems of bloom. In this competition the 1st prize and Silver Challenge Cup, to be held for one year, was won by C. J. A. NIX, Esq., Tilgate Lodge, Crawley, for an excellent collection, comprising good blooms of Mrs. G. H. Barr, Monarch, Glory of Leiden, and Lord Roberts representing the Trumpets; Lady M. Boscawen, Chancellor, Orangeman and Gloria Mundi, the Incomparabilis; Mermaid, White Queen, Maid of Athens and Fairy Queen, the Leedsii; White Slave, Fair Maiden, Sunrise, Incognita, the Barrii; and Virgil, Horace, Chaucer and Lycidas, those of the Poeticus. J. A. NIX, Esq., Crawley, won the 2nd prize. For twelve distinct varieties as above, Miss A. NIX, Tunbridge Wells, took the premier place, showing fine blooms of Lady M. Boscawen, Bedouin, Peter Barr, Evangeline, Weardale Perfection, Sunrise and Virgil. 2nd, Mrs. WADE-BROWN, Colgate. Mr. G. BANKS, Crawley, won premier honours in the classes for six varieties of Trumpet Daffodils, six varieties of Incomparabilis and six varieties of Barrii. F. BARCHARD, Esq., Uckfield, led for six distinct varieties of Leedsii Daffodils with Mrs. Langtry, Evangeline, Duchess of Westminster, Mlle. M. de Graaff and other varieties. W. C. BULL, Esq., Rams-gate, was 2nd. F. BARCHARD, Esq., was also successful for six distinct single varieties of true Poet's Narcissi. Mr. G. BANKS being 2nd. Miss WARREN was successful in the class for seedling Narcissi in three distinct varieties not yet in commerce, showing three lovely blooms of Secretary, Sophonisba and Kent, also for the finest single bloom of Trumpet Daffodil with Tommy Atkins. The finest single bloom of Incomparabilis Daffodil was shown by C. J. A. NIX, Esq., in Bernardino, and of Barrii Daffodil in Equinox. The finest single bloom of Leedsii Daffodil was Lord Kitchener, shown by Miss A. L.

NIX. F. BARCHARD, Esq., won the premier award for the finest single bloom of true Poet's Narcissus with a numbered seedling. The premier award for a collection of hardy cut flowering shrubs (grown in the open) was awarded to Sir EDMUND LODER, Bt., Leonard'slea, J. A. NIX, Esq., and Col. S. R. CLARKE, Cuckfield, being 2nd and 3rd respectively.

HUNTS SPRING FLOWER SHOW.

APRIL 17.—The ninth show of this society was held in glorious weather on the 17th inst. Fine breadths of Daffodils were shown by Messrs. J. AND R. PEARSON, R. H. BATH, LTD., C. BOURNE and J. MALLENDER, Bantry. The principal class for 20 varieties was won by S. F. STAFFURTH, Esq., J. CATOR, Esq., M.P., being second. Mr. Bourne's prize for the best single flower in the show was won by J. CATOR, Esq., M.P., with the variety Bedouin. The various competitive classes were well patronised and the competition was keen.

TORQUAY DISTRICT GARDENERS'.

APRIL 2.—The spring show of the above association, which took place in the new Town Hall, was one of the best held by the society. Entries were numerous, and the competition was very keen. The large hall showed off the exhibits to perfection, and the lighting was far better than in the Bath Saloons, where the shows have been held previously. The Silver Challenge Cup offered for Amaryllis was won outright by Mrs. J. LYON, who has now secured it on three occasions. As an honorary exhibit a fine Orange Tree was shown by Mrs. NICKSON, of Cary Castle, and a perfect and very large plant of Cyclamen by Mr. H. GORDON CUMMING. Nurserymen added much to the attractions of the show, the centre of the hall being devoted to their displays. Colonel CARY showed a very excellent group of Palms and Ferns, and a splendid specimen Palm, which won the 1st prize in the class for these plants. He was also successful in the classes for six flowering plants, six foliage plants, specimen Azalea, and group of greenhouse and stove plants. The Amaryllis plants that won the Challenge Cup were exceedingly beautiful, and gave evidence of the most careful cultivation. Cyclamen were very good, the 1st prize being won by Mrs. HASSALL. The prize for twelve pots of Hyacinths gained by Mr. F. PERSHOUSE was well won; and the six pots of Freesias that won the 1st prize for Mr. H. GORDON CUMMING were very fine. Colonel BURN, M.P., won the 1st prize for six pots of Tulips with excellent plants. Good culture was evident in the premier exhibit of six pots of Schizanthus shown by Mr. F. PERSHOUSE; and in the twelve pots of Polyanthus shown by Mr. H. E. BOWRING, who was awarded the 1st prize. Messrs. Sutton and Sons offered a special prize for twelve pots of Cineraria stellata, and it was won by Mr. F. PERSHOUSE. In the two vegetable classes Colonel CARY won both the 1st prizes, and there were also classes for perennes of flowers, and for table decorations.

Obituary.

HENRY LITTLE.—This much-respected amateur horticulturist passed away at his residence, Baronshalt, Twickenham, on Tuesday, the 14th inst., aged 81. Mr. Little was of the old school of garden lovers, and for many years a well-known figure at the meetings of the Royal Horticultural Society; he served for some time as a member of the Orchid Committee. Orchids were his favourite plants, and he possessed one of the best-grown collections of large-flowered Cattleyas, Laelias, Lycastes and other showy species. In recent years he added some hybrids to his collection, which he sold two or three years ago because he was no longer able to pass that time in the plant houses which he was in the habit of enjoying. Laelia purpurata of the best procurable varieties and Laelio-Cattleya elegans were special favourites, and as long ago as 1885

he gained awards for these plants at the Royal Horticultural Society. Deceased was a business man, and he took an active part in local affairs. He enjoyed robust health until the last few years, when heart trouble affected him.

EDWARD WALDRON GRIFFITHS.—The South African mail brings news of the death at Johannesburg on Tuesday, March 24, of Mr. Edward Waldron Griffiths, editor of *South African Gardening*, aged 37 years. Mr. Griffiths was a native of Cirencester, Gloucestershire, and went out to the Transvaal nine years ago in connection with the Government Agricultural Department of that Colony. Three years since Mr. Griffiths founded the paper, *South African Gardening*, which he edited with ability. He leaves a widow and a daughter.

ARRANGEMENT OF A SMALL POND: *E. A. C.*

Assuming that the bottom and sides of the pond are formed of concrete, with provision for draining off the water when necessary, there should be no difficulty in getting suitable plants to thrive. Your proposal to form "pockets" at the bottom of the pond has certain disadvantages in that the water would enter them and become stagnant, which even for water plants is not desirable. Rather than make pockets it would be better to build up loosely, or with slight connection by means of cement, cavities for holding soil, bordered with small pieces of stone or clinkers through which the water could percolate easily. With respect to the "pockets" above the water level, two different plans may be adopted: (1) Planting semi-aquatics with their roots in the water; (2) planting subjects that associate well with aquatics, yet do not require to be grown in moisture. For all of these purposes the soil should be sweet and fresh; good, tough turfy loam, mixed with road grit and decayed leaves will answer the purpose well. The following is a selection of plants:—Water plants: *Nymphaeas* of moderate growth, such as *N. ignea*, *N. Robinsonii*, *N. Leydekeri rosea*, *N. odorata*, *N. odorata rosea*, *N. sanguinea*, *N. virginialis*, and *N. pygmaea-helvetica*; *Aponogeton distachyum*. Both the *Nymphaeas* and the *Aponogeton* will cover the surface of the water with their leaves and flowers, and may be set in the deeper parts. For the margins, yet with roots growing in the water, you may plant *Zizania aquatica*, *Cyperus longus*, *Caltha polypetala*, *Glyceria aquatica*, *Alisma plantago*, *Butomus umbellatus*, *Menyanthes trifoliata*, *Richardia africana*, *Typha latifolia*, and *Myosotis palustris*. Outside of the pond proper provision may be made for the newer Astilbes, including *A. Ceres*, *A. Venus*, *A. rubella* (all with pinkish flowers), *A. Moorheimii* (white flowers), *Lythrum roseum*, *Epilobium angustifolium*, *Gunnera manicata*, *G. scabra* (of smaller growth than the last), English Irises, and *Gynerium argenteum*. For the centre of the islet one of the very best plants to use is *Senecio clivorum*, which is of handsome growth, and has beautiful trusses of yellow flowers in August. It is not advisable to plant *Arundo variegata* in such a position; as alternatives to *Senecio clivorum*, *Catha polypetala* or *Cyperus longus* would be suitable.

BEES INFESTING LAWNS: *F. W.* The bees are probably a species of *Andrena*; but as you did not send specimens we cannot say for certain. We know of nothing that will destroy the insects in their burrows; but the bees cause little or no injury to the turf, and they will disappear, for a season, in the course of a week or so.

BESCHORNERIA YUCCOIDES: *B. L.* *Beschorneria yuccoides* is a native of Mexico. It is a Yucca-like plant, with leaves 1 to 2 feet long. The inflorescence grows about 4 feet high, and bears bright-green, pendent flowers, with rosy-red bracts in summer.

BLUE HYDRANGEAS: *A. B.* A correspondent, writing in the issue for June 28, 1913, states that he used sulphate of ammonia freely when watering these plants, and without exception all the flowers became quite blue. The soil was of a peaty nature, but the roots had occasional dressings of Peruvian guano. The loam was free from lime, and the plants were potted in loam mixed with a little leaf-mould. See also the editorial note on this subject published in the issue for June 21, 1913.

CATERPILLARS ATTACKING RIBES: *J. E.* The injury is caused by the larvae of the common Magpie Moth, *Abraxas grossulariata*. The caterpillars may be readily collected by tapping the branches with the hand over an inverted umbrella or tray.

CRICKETS IN PLANT HOUSES: *G. H. W.* These pests are extremely difficult to eradicate from plant houses, and it will require persistent efforts to get rid of them, for their habits are nocturnal. They are particularly fond of heat, and are found in the greatest abundance near to stoveholes and in the vicinity of hot-water pipes, usually hiding in the crevices and holes in the walls during the daytime, and emerging as soon as it is dark. Crickets feed principally on vegetable matter, but are also fond of meat. Despite their timidity, they are combative in no small degree, and if two males are confined in a box they will fight until one is killed, and the victor then proceeds to eat the vanquished. They are particularly fond of the young, succulent shoots of seedlings, also the petals of many flowers. The following is a simple and effective method of exterminating these pests: Place a mixture of fresh beer and treacle in the bottom of a glass jam-jar to the depth of about 1 inch, and plunge the jar to the neck on a level with the border or walk; as an alternative use a small quantity of sweet oil. Frequently change the treacle-beer and the oil, as neither is attractive to the insects when rancid. In stoveholes and places not frequented by children or animals, you may employ a mixture of bread and white arsenic, using 1 ounce of the latter to 1 pound of the former. The poisoned bait may be sprinkled about the haunts of the crickets. It is advisable to adopt all three methods, and if you persist the crickets will in time be exterminated.

ERECTION AND HEATING OF VINERY: *W. M.* Allow a space of 12 feet between the floor-line and the bottom of ridge of the proposed three-quarter span vinery, and 16 feet between the front and back walls, with front ventilating sashes 1½ feet high, resting on 2 feet high 9-inch brick wall. The additional height of 2 feet between the floor and ridge will admit of longer rafters being used, and therefore afford greater scope to the vines to extend sufficient growth to maintain them in a vigorous and healthy condition. You will require three-flow 4-inch water pipes fixed at 1 foot from the front wall on piers about 1 foot above the surface of the border, and two returns running alongside the pathway about 3½ feet from the back wall. Thus arranged you will require about 380 feet of piping in addition to the necessary connections, including three-way and two-way outlet syphons and valves to regulate the heat in both flows and returns in each division. There being a rise of 4 feet in the ground on which you propose erecting your house the pipes can be fixed at the same distance from the wall plate the full length of the house. Either socketed pipes with joints made of a few rounds of yarn and cement to finish off with, or plain-end pipes connected by indiarubber joints may be used. Both are effective and easily-made joints; the indiarubber joints are a little more expensive, but as easy to take apart as put together, which circumstance is an advantage. You propose making your house in three divisions. Make the section nearest to the boiler the plant house; No. 2 your early vinery; and No. 3 your late vinery. Thus arranged you will be able to economise and control the artificial heat to advantage. A No. 7 B "Junior Robin Hood" sectional boiler, capable of heating 480 feet of 4-inch piping, would answer your purpose.

NAMES OF FRUITS: *Ponica.* Apple Northern Spy.—*D. K. S.* Apple D'Arcy Spice.

NAMES OF PLANTS: *T. G. S., Wales.* *Solanum jasminoides*.—*T. and S.* *Sparmannia africana*.—*F. R.* 1, *Petasites officinalis*; 2, *Veronica Traversii*; 3, *Juniperus communis*; 4, *Prunus cerasifera atropurpurea (Pissartii)*; 5, *Spiraea prunifolia flore pleno*; 6, *Ligustrum coriaceum*.—*L. Pulkinghorne.* *Pittosporum tenuifolium*.—*D. Rose.* 1, *Spiraea prunifolia flore pleno*; 2, *Rubus spectabilis*; 3, Please send when in flower; 4, A Gourd, a form of *Cucurbita Pepo*. Seeds should be sown at once in heat and the young plants grown on indoors until the middle of June, when they should be planted out of doors in a sunny position and trained to stakes or trellises.—*W. S., Lincoln.* *Corydalis bulbosa* (the tubers can be purchased from nurserymen).—*W. K. T. L.* 1, *Magnolia conspicua*; 2, *Isoloma hirsuta*; 3, *Acalypha musaica*; 4 and 5 are apparently garden forms of *Bouvardia*, but we cannot help you with specimens of this kind unless they are in flower.—*G. W. H.* Probably *Eryngium pandanifolium*. Send flowers with leaves later.—*F. T.* 1, *Oncidium varicosum*; 2, *Oncidium pubes*; 3, *Ada aurantica*.—*Cotford Gardener.* *Eriobotrya japonica*.

NURSERY MANAGER'S NOTICE: *Moreover.* The length of notice which should be given to the manager of a nursery business residing on the premises is a matter of trade custom, and the general opinion in the trade appears to be that one month's notice, expiring at any time of the year, would be the customary period.

PRIMROSES: *Finborough.* The common Primrose succeeds best in a deep soil that is uniformly moist and contains a fair proportion of humus. If the situation is fully exposed the climate should be cool and moist. When grown in partial shade, such as in a thinly planted coppice, a dry period will not cause the plants much injury. Were your plants moved at a suitable time? November and the three following months are the best in which to transplant Primroses. The Oxlips and "Five Fingers" have come from seed, and have nothing to do with the Primroses.

PRIMULA FORRESTII: *Dorset Gardener.* *Primula Forrestii* grows wild in crevices of limestone rocks, and may be cultivated as a crevice plant in the rock garden, planted in loamy soil. The plant requires protection during the winter.

VINES: *A. G., Polgate.* If your vine rods are not more than three feet apart there will only be space for two leaves beyond the bunch by the time the shoots have expanded to their full length, supposing they are fairly vigorous. All sub-laterals should have been removed as they appeared, excepting the one nearest to the main rod, and that should be kept pinched to one leaf. You may now remove them gradually, not too many at one time. If the rods are four feet apart four leaves should be left beyond the bunch, and should the shoots have been already stopped too severely an extension may be allowed, it matters not whether it is on the main shoot or terminal sub-lateral, the object being to have as many leaves as can be exposed fully to the light. If there is room for the leader to extend, and provided the laterals at the base of the rod are of equal strength with those of the top, extension may be allowed; but in opposite conditions the leader and uppermost laterals might be stopped with a view to increasing the strength of the lateral below them. All the side-shoots may be allowed to make one leaf each on the extension of the main rod. Should the space be already filled, the end shoot should be treated similarly to those on each side of the rod.

THE HISTORY OF CULTIVATED FRUITS

AS TOLD IN THE LIVES OF GREAT POMOLOGISTS.

IV.—DUHAMEL DU MONCEAU.

IT is no exaggeration of language to say that the science of pomology dates from 1768, the year of publication of the classic work of Duhamel du Monceau entitled *Traité des Arbres Fruitières*. To appreciate in what way it represented an advance on all previous treatises it is necessary to review briefly the literature of pomology up to that date.

In France there had been no lack of books upon the culture of fruit, but while the two outstanding authors—Olivier de Serres and De la Quintinye—had treated in great detail all cultural matters, the descriptions of fruits were very incomplete. Quintinye, it is true, occasionally devoted some lines to the description of a fruit, but dismissed others with a few words. Germany did not produce any great pomologists until 1776, when Mayer published his *Pomona Franconia*. Before this date his countrymen drew very largely upon French authors for their matter, and it was not till the end of the eighteenth and the beginning of the nineteenth centuries that Christ, Diel, Siekler, and others laid the foundations of the great German school of pomology. The *Pomologia* of

Knoop, published in Holland in 1763, was in many respects a great advance. The coloured plates, though somewhat crude to modern eyes, must have caused something of a sensation at the time. We cannot, however, claim for Knoop a prominent position in the line of descriptive pomologists, as the few words he devotes to each fruit leave much of importance unsaid. In England the only work of real merit, apart from cultural value, was the *Pomona* of Batty Langley. This folio, published in 1729, contains short descriptions and outline drawings of considerable merit. All these works, however, confine themselves to descriptions of the fruit. It was Duhamel's great merit to add to this a careful description of the tree in all its parts. Even now the great importance of these full descriptions for accurate identification is not fully recognised. The written description alone, at its best, is often a frail support, and when confined to the fruit only it is frequently hazardous to rely upon it.

HENRI LOUIS DUHAMEL DU MONCEAU.

It is remarkable that the development of pomology has followed, in many respects, that of botany in its disregard at first of the plant as a living entity. The older school of botanists, with its sheets of dried specimens, is strongly suggested by the pomologist in his fruit room studying fruits and disregarding the living tree with its strong individualities. The study of fruits as museum specimens has led to many errors which a knowledge of tree characters would have prevented.

We owe, therefore, to Duhamel the introduction of a botanical exactness into the study of pomology, and for this reason systematic pomology may be said to date from this day.

The family of Duhamel was of Dutch origin, but his parents had settled in Paris before he was born. His student days were not remarkable for close application to work. His interest was given to so many subjects that it is not surprising that his knowledge was wide rather than deep. Botany, however, attracted him from early days, and on leaving college

he lodged near the King's Garden at Paris, now the Jardin des Plantes. Here he made the acquaintance of the chief botanists of the day—Dufay, Geoffroy, Jussieu, Vaillant, and others of the talented group which Royal patronage had brought together. He rapidly gained the good opinion of those in power, and when twenty-eight years of age he was selected by the Académie Française to examine a disease which was causing damage to the important Saffron crop. The satisfactory result of his investigations gained him membership of the Academy, and from this date he produced a variety of books upon technical subjects. His versatility and curiosity seem to have been endless. Some forty-two works were written by or attributed to him on such diverse subjects as tobacco pipes, wax-making, refining sugar, the manufacture of Turkey carpets, ship-building, brick-making, etc. Added to this, he held the office of Inspector-General of Marine. It is, therefore, rather doubtful how far the above-mentioned books can be considered as the result of his own observations and pen. In the case of the *Traité des Arbres Fruitières*, it is known that he received considerable help from several persons. Chief among these was his brother Denainvilliers, who spent his country retirement in a study of fruits. Living near to Duhamel's country house, opportunities for collaboration, no doubt, occurred frequently; but we may be pardoned, knowing the great activity of Duhamel's life, if we consider that his share in the work was probably not the largest. Valuable aid, too, was given by Le Berriays, without whose enthusiasm the book might never have been written; by M. Richard, the famous gardener at the still more famous gardens of the Trianon; and, lastly, by M. Hervey, head gardener to the Chartreux Frères at Paris, to whom we owe the preservation of so many old varieties of fruits, and whose nursery was then one of the few places in Europe where purchasers might be certain of correct nomenclature.

There is, however, but little doubt that Duhamel's botanical training is reflected in the minute descriptions of fruit, wood, leaf, and flower, which mark out this work as setting a new standard. In an interesting preface he discusses with much acuteness those characters which are sufficiently constant to be selected as recognition marks. Special stress is laid upon the fruit bud, its form and colour; the spur leaves, especially with reference to the margin, if crenate or serrate, etc.; and on the flowers, in respect of form and colour. The variation of the fruits from local causes is recognised, and the need for an examination of the character of the flesh and seeds is emphasised. The chief subject for regret is that no historical details of the fruits are given. Coming, as Duhamel did, before the great outpouring of new fruits by Van Mons, Esperen, Knight, and other raisers, his material was chiefly what may be called the classic fruits of France, and particulars of origin would have been of the greatest value. However, with so much that is valuable and new, it is perhaps churlish

to criticise this deficiency. The selection of varieties is mainly limited to what we now call dessert fruits, and breaks away from Quindinye, whose lists up to this date had an authority almost pontifical in France and elsewhere.

The two volumes in which this work was published are notable for fine printing, and the plates are of the greatest value. Unlike many works, before and after, they combine excellence of execution with exact pomological detail. As an example may be mentioned the leaves of the Apples. The differing forms of marginal division are most accurately depicted, a quality to which few pomological drawings can lay claim.

This work was used as the basis of a fine work in two folio volumes with coloured plates by Redouté and Bessa, and edited by Mirbel, Poirét, and Loiseleur Deslongchamps. This passed through three editions, each of which was extended, and the last—by Poiteau and Turpin—is perhaps the most beautiful and complete work upon fruit ever published.

The name of Duhamel has been commemorated in botany by the name of Hamelia, given to a South American plant, but to pomologists he will always be remembered as a pioneer in that descriptive exactitude, by which alone the study of systematic pomology can be advanced. *E. A. Bunyard.*

NEW OR NOTEWORTHY PLANTS.

WHAT IS PYRUS CORONARIA LINN.?

In the concluding part of the second volume of Prof. Sargent's valuable publication, *Trees and Shrubs*, issued recently from the Arnold Arboretum, Mr. Alfred Rehder reviews the species belonging to the Coronariae section of Malus, which, following Miller, is here kept distinct from the genus Pyrus. This is an arrangement which no doubt has much to recommend it, but it is to be regretted that the author should have considered it necessary to discard the name Malus (or Pyrus coronaria Linn.) in favour of Malus fragrans Rehder, a piece of name-juggling which, after careful investigation of the facts, appears to be wholly unnecessary. Miller's Malus coronaria is, of course, based on the Pyrus coronaria of Linnaeus, which he described in *Species Plantarum*, ed. I., p. 480 (1753). It so happens that Linnaeus cites Gronovius' Malus "Sylvestris floribus odoratis," Flora Virginica, as a synonym of the species. The latter work, first published in 1739, is a description of the plants collected by John Clayton in Virginia; and Clayton's specimen, labelled Pyrus coronaria, in the British Museum herbarium, proves on examination to be the same plant as that described subsequently by Aiton in the *Hortus Kewensis*, II., p. 176 (1789), as P. angustifolia. Mr. Rehder makes this an excuse for transferring the name Pyrus coronaria to Aiton's plant and giving a new name to the Crab tree, which has been grown for so long in English gardens under the latter name. Such a change can only result in confusion and has nothing to recommend it; there is, indeed, no evidence to support it. Mr. Rehder has overlooked the fact that there is in the Linnean herbarium a specimen labelled Pyrus coronaria in Linnaeus' handwriting. This was collected by Kalm in North America, and, although a mere scrap, is sufficiently characteristic to enable us to decide what he meant by his Pyrus coronaria, for it answers the description "Foliis serratis angulosis," which Clayton's plant does not; in the latter specimen the leaves are not angularly serrate, but have small crenate serrations. I have fortunately been able to ascertain the history of the Linnean specimen through the kindness of Dr. B. Daydon Jackson, who says that "Kalm arrived in Stockholm in June, 1751, and brought with him the actual

specimen now in Herb. Linn. There was therefore abundant time for Linné to write his diagnosis with Kalm's plant before him. The scrap which was all that Kalm brought to his old professor with his account of it was surely enough to constitute what the Americans call a 'Holotype'—the one specimen upon which the species was described." Linnaeus very possibly remembered Clayton's specimen, but no doubt regarded it as the same as that from Kalm in his herbarium, and upon which he based his description. That this was so is evident on turning to *Species Plantarum*, ed. II., p. 687 (1763), where he amplifies his previous description and gives a reference to Kalm's plant as well as to the Flora Virginica. That the plant in the Clayton herbarium does not agree with the description in *Species Plantarum* may be explained by the fact that Linnaeus had not seen the specimen for some years. Moreover, it is well known that references quoted by him as synonyms under a particular species often turned out to be distinct plants.

Again, there is nothing to support Mr. Rehder's views that Miller's Malus coronaria is synonymous with Pyrus angustifolia Aiton. The account in the dictionary is absolutely against it, and points altogether to the fact that it was the same as Kalm's plant. To begin with, Miller quotes as a synonym "Malus sylvestris virginiana floribus odoratis," from the *Catalogue of Trees, Shrubs and Plants (Cultivated)*, published in 1730, at which time, as Mr. Rehder himself states, "P. angustifolia had not been introduced into cultivation." As a matter of fact, it was not introduced until twenty years later, so it is most unlikely that his "Malus sylvestris virginica" can have referred to this tree. Also, it is misleading to say that Miller gives no description of the tree. In the *Dictionary* he says: "The leaves of this are longer and narrower than any of the other sorts and are cut into two acute angles on their sides,"

which is entirely characteristic of Pyrus coronaria as hitherto understood by botanists. Mr. Rehder says that Miller speaks of his Malus coronaria as a plant tender in England, and considers this to indicate that he refers to P. angustifolia, which is known to be more tender than P. coronaria. I do not find any such statement in the *Dictionary*. On the contrary, in the 1730 catalogue referred to above Miller distinctly implies that the tree is hardy, for, according to the second title-page, which Mr. Rehder seems to have missed, the plants described therein are, to use Miller's own words, "hardy enough to bear the cold of our climate in the open air." I think I have discussed the matter at sufficient length to show that Malus fragrans Rehder must be rejected, and that the names in use for these two trees during the last 160 years are perfectly valid. The citations set out below show the correct nomenclature for the species in question:—

Pyrus coronaria Linn., *Sp. Pl.*, I., p. 480 (1753). Malus; sylvestris virginiana, floribus odoratis. Miller. *Cat. Trees and Shrubs*, 47 (1730). Malus coronaria. Miller. *Dict.*, ed. 8, No. 2 (1768). Malus fragrans Rehder. Sargent. *Trees and Shrubs*, Vol. II., part 4, 228 (1913).

Pyrus angustifolia Aiton, *Hort. Kew.*, II., 176 (1789). Sargent, *Silva*, N. Am., IV., 75 t. 169 (1892). Pyrus coronaria var. angustifolia, *Wenzig in Linnaea*, XXVIII., 41 (1874). Malus angustifolia Michaux, *Fl. Bor. Am.*, I., 292 (1803). Malus coronaria Rehder. Sargent, *Trees and Shrubs*, Vol. II., part 4, 229 (1913), non Miller. *A. Bruce Jackson.*

ORCHID NOTES AND CLEANINGS.

HYBRID ORCHIDS.

(Continued from March 21, p. 201.)

Hybrid.	Parentage.	Exhibitor.
Brasso-Cattleya Massangeana	C. Trianae × B.-C. Mrs. J. Leemann	M. Theodore Pauwels.
Brasso-Cattleya Princess Elizabeth	B.-C. Digbyano-Mendelii × C. Mossiae	Charlesworth and Co.
Brasso-Laelia Galba	B.-L. Digbyano-purpurata × L. splendens	Flory and Black.
Brasso-Laelio-Cattleya Amrole	B.-L. Mrs. Gratrix × L.-C. luminosa	W. H. St. Quintin, Esq.
Brasso-Laelio-Cattleya Taurus	L.-C. Cambamiana × B. Digbyana	Armstrong and Brown.
Cattleya Gravesiana	Mossiae × Ludlemanniana	Sander and Sons.
Cypripedium Jezebel	Arthurianum pulchellum × Mrs. Wm. Mostyn	Lt.-Col. Sir G. L. Holford, K.C.V.O.
Cypripedium Redwing	G. F. Moore × nitens-Leemann Hamibal	Lt.-Col. Sir G. L. Holford, K.C.V.O.
Cypripedium Royal Emblem	concolor × aureum Oedippe	Sander and Sons.
Cypripedium Winsum	callosum Sanderiae × Winifred Hollington	F. M. Ogilvie, Esq.
Dendrobium Bassetti	Rolfae × melanodiscus	Mrs. Haywood.
Dendrobium Frederickii	fimbriatum × Thwaitesiae	R. G. Thwaites, Esq.
Laelio-Cattleya anabilis Fascinator	L.-C. Fascinator albens × C. Ludlemanniana Stanleyi	Charlesworth and Co.
Laelio-Cattleya Avoca	L. Latona × C. Trianae	H. T. Pitt, Esq.
Laelio-Cattleya Azora	Ophir × Charlesworthii	Stuart Low and Co.
Laelio-Cattleya Decius	L.-C. Hippolyta × L. pumila	Flory and Black.
Laelio-Cattleya Flavius	L.-C. G. S. Ball × L. flava	Flory and Black.
Laelio-Cattleya Geta	L.-C. Picams × C. Schroderae	Flory and Black.
Laelio-Cattleya Goldilocks	C. Harrisoniana × L. Cowanii	O. O. Wrigley, Esq.
Laelio-Cattleya Latoglossa	L. Latona × L.-C. callistoglossa	Stuart Low and Co.
Laelio-Cattleya Juncuda	C. Percivaliana × L.-C. Edwardii	Sander and Sons.
Laelio-Cattleya Ossian	L.-C. highburiensis × L.-C. Pallas	Flory and Black.
Laelio-Cattleya Tigris	L. Cowanii × L.-C. Dominiana	Lt.-Col. Sir G. L. Holford, K.C.V.O.
Laelio-Cattleya Tobina	C. Trianae × L. Boothiana	Eustace F. Clark, Esq.
Laelio-Cattleya Vincent	C. Trianae × L.-C. Doris	Sander and Sons.
Odontioda Arthur	Oda. Bradshawiae × Odm. ardentissimum	Mrs. N. Cookson.
Odontioda Brackenhurst	Oda. Charlesworthii × Odm. eximium	J. Gurney Fowler, Esq.
Odontioda Brunette	Oda. Bohnhoffiae × Odm. Harryannum	J. Gurney Fowler, Esq., and Messrs. Charlesworth.
Odontioda Elsie	Oda. Charlesworthii × Cochlioda Noezliana	Charlesworth and Co.
Odontioda Graireana	Cochlioda Noezliana × Odm. Rossii	M. H. Graire.
Odontioda Joan	Odm. Charlesworthii × Odm. ardentissimum	Charlesworth and Co.
Odontioda Mrs. R. le Doux	Oda. Bradshawiae × Odm. Wilkeannum	R. le Doux, Esq.
Odontioda oakwoodense	Oda. Bradshawiae × Odm. percutum	Mrs. N. Cookson.
Odontioda Zenobia	Oda. Charlesworthii × Odm. percutum	F. M. Ogilvie, Esq.
Odontoglossum ardentillius	ardentissimum × illustrissimum	Armstrong and Brown.
Odontoglossum eximillius	eximium × illustrissimum	Armstrong and Brown.
Odontoglossum Mozul	Parentage unrecorded, oakwoodense × ardentissimum (Canary) incorrect.	Sir G. L. Holford, K.C.V.O.
Odontoglossum Newlingii	Ossulstonii × cirrhosum	R. G. Thwaites, Esq.
Odontoglossum Rolosa	Rolfae × Ossulstonii	De B. Crawshaw, Esq.
Odontoglossum Royal Purple	Edwardii × illustrissimum	Armstrong and Brown.
Odontoglossum Ulysses	excellens × Lambeanianum	Armstrong and Brown.
Odontoglossum Uranosa	Urania × Ossulstonii	De B. Crawshaw, Esq.
Odontoglossum Valeirra	Vuystekei × cirrhosum	R. G. Thwaites, Esq.

Odontoglossum Zena	Scepterum × Harryannum	De B. Crawshaw, Esq., and Lord Granley.
Odontoglossum Edna	Rossii rubescens × ardentissimum	R. G. Thwaites, Esq.
Odontoglossum Leonidas	Hallio-crispum × triumphans	De B. Crawshaw, Esq.
Odontoglossum Mirabeau var. Mastiff	nirum × Lambeanianum	J. and A. McBean.
Odontoglossum Titania	Queen Alexandra × crispum	De B. Crawshaw, Esq.
Sophro-Laelio-Cattleya Sunloch	L.-C. Goldfinch × S.-L.-C. Danae	Lt.-Col. Sir G. L. Holford, K.C.V.O.

ODONTOGLOSSUM MOGUL.

At the meeting of the R.H.S. Orchid Committee on April 7 last Lieut.-Colonel Sir Geo. L. Holford, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), showed *Odontoglossum Mogul*. This hybrid, which received a First-class Certificate, furnishes an instance of a recorded parentage proving to be inaccurate, for it was said to have been derived from *O. oakwoodense* × *O. ardentissimum*. It required but a glance at the illustration of *O. Canary* (*oakwoodense* × *ardentissimum*), in the *Gardeners' Chronicle*, January 17, 1914, and the accompanying note of that pretty yellow variety, to show that a mistake had been made.

O. Mogul (parentage unrecorded) is one of those beautiful but puzzling variations which the hybridist is delighted to welcome. That *O.*

period of any flowering climber, commencing to expand its blossoms towards the end of April, flowering in ever-increasing profusion through the summer months, and reaching the zenith of its display in September, when it forms a sheet of snowy blossoms, while it often retains some at least until Christmas.

Lapagerias succeed admirably on a north or north-west wall in the open in Devon and Cornwall, and long trails of waxy-petalled, tubular blooms, white and red, may often be cut so late as November. The white-flowered *Physianthus albens* will also grow freely, spreading widely over a wall or sheltered cliff face. It also bears numbers of its great, corrugated seed-pods. *Stauntonia latifolia*, although bearing somewhat inconspicuous flowers among its leathery leaves, is valuable on account of the exquisite fragrance emitted by its clustering blooms in the early

bloom appeared in these columns a few months ago (fig. 73, Sept. 20, 1913). In specially sheltered sites there are three other beautiful flowering climbers which may be grown on warm south walls. The first of these is *Plumbago capensis*, which bears pale blue flowers. A plant of this growing at the foot of a lofty cliff, by which it is protected on the north and east, has passed through several winters without any artificial sheltering, and in the early autumn is a sheet of palest blue. The second is *Mandevilla suaveolens*, a native of Buenos Ayres, a handsome greenhouse climber, bearing in great abundance clusters of large, deliciously scented white blossoms. In many gardens this grows well and flowers profusely in the open. The third is the Ivy-leaved *Pelargonium*, which in the south-west is largely used as a wall-climber. *Abutilon megapotamicum*, from Rio Grande, although not

FIG. 129.—ODONTOGLOSSUM MOGUL: PETALS AND SEPALS BLOTCHED WITH CLARET-PURPLE.
(R.H.S. First-class Certificate on April 7, 1914.)

ardentissimum may be one parent is possible, for *O. Pescatorei* seems well indicated in the whiteness of the ground colour and form. The colour of the blotches is claret-purple, with a ruby-red tint on the central part.

TENDER CLIMBERS FOR FAVOURED LOCALITIES.

THE best of half-hardy flowering climbers is, without doubt, *Solanum jasminoides*, the attractive qualities of which are widely recognised in Devon and Cornwall, where it is largely grown by rich and poor alike. Its white flower-clusters are extremely beautiful, and were these borne merely for the space of a month or six weeks, would entitle the plant to a foremost place among climbers. As a matter of fact, however, the *Solanum* enjoys the most extended blooming

spring. In the autumn the long, sausage-shaped seed-pods, dull crimson in hue, are freely produced. The great Burmese Honeysuckle, *Lonicera Hildebrandiana*, is a glorious plant bearing hundreds of large flowers 6 inches in length and 5 inches across the open lip. These are at first white, but turn to deep orange, and their fragrance is unrivalled. This year the plant bore dozens of seed-pods. Two *Tacsonias*, *T. quitensis* and *T. mollissima*, both natives of Quito, do well in the south-west. The first bears flesh-coloured flowers, and the second reddish pink. The New Zealand Clematis, *C. indivisa lobata*, is, when in full flower, one of the loveliest plants it is possible to imagine. It grows well in the open in Devon and Cornwall, and when a wall 40 feet in length and 8 feet in height is entirely covered with thousands of its large white flowers, the effect is indescribably beautiful. An illustration of a plant in full

strictly speaking a climber, may be grown against a wall with its main growths trained in, when its arching flower-laden shoots bend outwards gracefully, studded along their length with their crimson and yellow blooms, which are borne in quantity throughout the whole summer and autumn and well into the winter months. *Manettia bicolor* is a pretty climber, bearing tubular red and yellow flowers for many months. It does well in many gardens. *Akebia quinata* is a perennial flowering climber bearing sweetly-scented flowers of maroon colour. This note is far from exhausting the list of charming half-hardy flowering climbers and other plants that may be utilised for beautifying wall and trellis in the warmer districts of our islands, but sufficient have been mentioned to give an idea of the scope afforded by this branch of gardening in specially favoured localities. *Wyndham Fitzherbert.*

BELVOIR IN SPRING.

(See Figs. 130, 131, 132, 133, and Supplementary Illustration.)

THE paragraph inserted in these pages last week announcing the fact that the spring flowers at Belvoir Castle, the ancient home of the

completion, a large portion was destroyed by fire. The building, however, proceeded, and the destroyed portion was rebuilt with different stone, consequently the appearance to-day would lead the visitor to imagine that one portion was very much older than the other, which is not the case. On the south side are some very fine terrace walls,

ally from the late Sir Thomas Hanbury's garden at La Mortala; *Ozothamnus rosmarinifolius*, *Clerodendron foetidum* and *C. trichotomum*, and *Indigofera Gerrardiana*. On the next wall above were noticed a fine plant of *Azara merophylla*, *Magnolia Soulangiana* in full bloom (see fig. 131) and *M. grandiflora*, *Chimonanthus fragrans*, *Calycanthus occidentalis* and *C. floridus*; Lilacs and *Olearias*. The next terrace above is called the flower-garden terrace. At the east end a fine plant of *Photinia serrulata* grows against the wall to a height of 20ft. *Fabiana imbricata*, *Lonicera fragrantissima*, *Punica granatum*, and a large Banksian Rose 23ft. high and 40ft. wide at the top. There is yet another terrace at the back of this high wall, which is only about 3ft. below the top. It is believed that these beautiful walls were built at about the same time as the castle. From the uppermost terrace the view is one of extreme beauty, contributed to by the elevation and also by the magnificent trees, for Belvoir is specially fortunate in possessing a wondrous collection of handsome specimens. The N.E. side provides a view of the surrounding country extending for miles.

The "Castle Flower Garden" is a triangular piece of ground near the carriage approach to the castle. In the centre is a large plant of the North American *Magnolia umbrella*, a species that produces greenish-white flowers early in June and very fine foliage. Around this tree there are several beds that used to form part of the spring bedding, but several years ago this garden was altered to the formal style. A stone wall now encircles the *Magnolia*, the paths are paved with flags, and the beds contain low hedges of Lavender, Paeonies, etc., with the usual bay trees in tubs and statuary and objects of art that the present Duchess has gathered together from remote places abroad, whilst a small tank in the shape of a half-moon contains choice Water Lilies.

FIG. 130.—VIEW IN THE "DUCHESS" GARDEN" AT BELVOIR CASTLE.

Dukes of Rutland, were now at their best, was doubtless read by many who would like to benefit from the intelligence thus given, but are unable to do so. This seems the more probable, because a quarter of a century has elapsed since the present writer first indulged hopes of making the Belvoir visit, yet so long is hope sometimes deferred that not until Friday in last week were his wishes fulfilled. It is likely, therefore, that certain impressions of Belvoir, gained as the result of the visit, may be of interest to many readers of these pages. From Bottesford Railway Station, on the Great Northern Railway, the castle is reached after a drive of five miles, and as one approaches the estate it becomes evident that the last mile will be a gradual ascent from the level country behind to the hill on which the castle is situated. The hill rises to a height of 456 feet, and at its foot the meadows are covered with the yellow bells of the Cowslips, showing that the land is heavy and damp; in point of fact, two, and sometimes three, horsea are required to the plough. The depth of the clay subsoil has not been determined, though borings to a considerable depth have been made for the purpose. The present castle, which is seen above the trees in fig. 132, was commenced in the year 1801 by John Henry, fifth Duke of Rutland, but in 1816, when nearing

dropping down one under the other to the base of the first hill. On the lowest wall there are many

FIG. 131.—MAGNOLIA SOULANGIANA ON TERRACE WALL AT BELVOIR.

interesting plants, such as *Abutilon vitifolium*, *Prunus triloba*, *Berberidopsis corallina*, a single yellow Banksian Rose, that came origin-

The statuary garden, on the west side of the garden, was illustrated in a supplement to *Gardeners' Chronicle*, March 7, 1903, and calls

for no remark now, except that it was formed in its present position in 1847 by Mr. Challis, who was head gardener at Belvoir for a short period.

view was from above. Here also are Himalayan Rhododendrons—*H. Thompsonii*, for example—covered with blossoms, enhancing the effect produced by the *Acer*; plants of *Kerria*

Rising from the hollow and pushing their way up through the various forms of vegetation, are the tall columns of *Cupressus Lawsoniana*, relieved by magnificent groups of Bamboos, whose graceful stems lend an aerial brightness to the somewhat gloomy limbs of the *Cupressus*. Some of the most effective of the Bamboos are *Arundinaria japonica*, *A. falcata* (14ft. high by 21ft. through the branches, planted in 1882), *A. Simonii* (14ft. high), *Bambusa viride glaucescens* (11ft. by 17ft.), the dwarf *B. tessellata*, growing at the side of the pathway, and *B. Fortunii variegata*.

Gratifying success has been attained in this garden with more or less tender plants, considering the locality, and the following are all to be seen, represented by good specimens:—*Daphniphyllum glaucescens*, *Trachycarpus excelsa*, *Azara microphylla*, *Staphylea colechica* (16½ft. by 17½ft.), *Halesia tetraptera*, *Paulownia imperialis* (planted in 1903), *Azalea amoena*, *A. balsamiflora*, *Andromeda ovalifolia*, *A. floribunda* and *japonica*, *Eucryphia pinnatifolia* (25ft. high) and *Embothrium coccineum*.

THE SPRING FLOWERS.

In the glorious setting provided by the Duchess' garden, the spring flower garden at Belvoir has everything in its favour. The late Mr. William Ingram, who, with Mr. Wildsmith, of Heckfield, was amongst the first to develop this form of gardening, may be credited with having realised this fact at the

FIG. 132.—BORDER OF HARDY PERENNIALS AT BELVOIR CASTLE.

THE DUCHESS' GARDEN.

The Duchess' garden, lying to the west of the castle, is named after the Duchess Elizabeth, wife of the fifth Duke, who first chose the site. It occupies a natural hollow on the side of a hill, about half a mile from the castle. The area is eight acres. In shape it resembles a horseshoe, with the open part of the shoe facing south-east. The character of the hollow will be understood when it is realised that the fall from the highest to the lowest point is something like a hundred feet. The whole of this garden is sheltered by tall forest trees, which completely encircle it, whilst the sloping banks provide excellent situations for many tender shrubs, both foliage and flowering, which would not be capable of existing here were it not for the shelter, first of the slopes, and secondly of the trees already mentioned.

It would be difficult to imagine a more beautiful scene than that presented by this valley, densely covered as it is with choice and luxuriant vegetation, the trees ranging from 150ft. giants down to the dwarf undershrubs. Beds filled with lovely spring flowers are placed in the most effective positions, as, for instance, on the higher grassy slopes or level tracts near the bottom of the glen. The scenery reminds one of some favoured chine—Shanklin, for example—but it is superior in every respect. The visitor may walk round this valley on a path formed at the top of the slopes, and thus command a view of the whole. Seen from above, the garden presents to the eye a wealth of green growth of all kinds, varied and relieved by occasional patches of vivid colour. One of these latter is provided by a plant of *Acer japonicum septemlobum*, an extraordinarily fine specimen, and probably one of the first to be planted out-of-doors in this country. It is upwards of 20ft. high, and measures 30ft. through the branches. Readers may imagine the magnificent effect of the clear April sunshine lighting up the brown-red colour of this eastern Maple, the effect being all the better because the

japonica flore plena, with rich, orange-coloured flowers; tall, thick bushes of Camellias, in excellent health and in full flower, planted thirty

years ago, both red and white varieties; Rhododendron Falconeri, with its sulphur-coloured flowers, and other Himalayan species of Rhododendron could be seen on the slopes of the dell.

FIG. 133.—WISTARIA SINENSIS AT BELVOIR CASTLE. Portions of the plant have been detached from the wall and trained to poles the better to display the flowers.

years ago, both red and white varieties; Rhododendron Falconeri, with its sulphur-coloured flowers, and other Himalayan species of Rhododendron could be seen on the slopes of the dell.

outset, namely, that it was extremely well suited to the surroundings. Mr. Ingram was gardener at Belvoir for the long period of 40 years, and his successor, Mr. W. H. Divers, who has held

the position for the past 20 years, has developed the system, so that for upwards of half a century spring flowers have been a speciality at Belvoir. The example of Belvoir has had its effect over the country, inasmuch that it is difficult for the younger generation of gardeners to imagine the great development that has taken place, and to realise that before a few resourceful men turned their attention to the subject and studied the plants that seemed to possess the necessary qualities for winter and spring decoration the beds in most gardens were often allowed to remain bare through the long winter and spring seasons. This is rarely the case nowadays in gardens of any pretension, and the modern visitor to Belvoir, therefore, when he beholds the splendid displays of colour, recognises that here is indeed the classic example from whence this and that feature have been copied in countless instances. Such being the case, it could hardly be expected that the beds should have the same stamp of novelty that belonged to them in former years; indeed, the chief points about them are (1) that they are more favourably situated than probably any others in the country; (2) that greater attention is paid to detail, with the result that the plants are more successful; and (3) that the experience of so many years enables Mr. Divers to obtain perfect colour effects. The system of massing is just the same as in summer bedding, as will be seen in the illustration (fig. 130). There are ribbon borders, with some design occasionally running through them, and beds planted wholly with one colour, just as they used to be in the summer, with selected varieties of zonal Pelargoniums or Calceolarias. This year, for instance, the most effective design is planted as follows, the various subjects forming straight or zig-zag lines or panels of various shapes. At the top, Wallflower Ruby Gem, with double Daisies under them; then Aubrietia deltoidea (mauve); next Wallflower Salmon Queen, followed by Aubrietia Hendersonii, with red Hyacinths amongst the Aubrietias; tall double-flowered Wallflowers, with broad bands of pale-blue Forget-me-nots at the base, and blue Hyacinths mixed with them. The larger beds are each massed with one variety, and in one of them Wallflower Fire King, edged with yellow Polyanthus, is uncommonly effective. Wallflower Fire King is peculiarly bright, and those who have not cultivated this somewhat new variety are recommended to make a trial of it. April was too early for many of the Tulips to be in flower, as it was for many other plants in Mr. Divers's select list, but of Daffodils there appeared to be millions, growing in every conceivable situation, and succeeding in the grass no less well than in the beds. Mr. Divers contrives very cleverly to get drifts of Daffodils in just the form and situation to produce effects that please the artist, for they appear as if Nature herself had distributed the bulbs. Many have succeeded in the grass for a period of thirty years, and their strength of flower and foliage is indeed remarkable. In the kitchen garden, which covers an area of seven acres, there are great breadths of Daffodils on the borders, and in the plantations and pleasure grounds generally they light up countless situations between the shrubs.

These notes can only attempt to give the reader some imperfect idea of the glories of Belvoir in spring, for there are many other features that might be remarked upon did space permit, the herbaceous flower garden, for instance, a border of which is illustrated in fig. 132. The general condition of the place is exceedingly good, and highly creditable to Mr. Divers, who has cared for it so many years.

For the information of readers who may like to study the subject of spring gardening in greater detail, it may be mentioned that Mr. Divers has recently published a book* on the subject of

very great value to those engaged in the same kind of work, and figs. 130, 131, and 132 are reproduced from that interesting volume. In conclusion, we reproduce from the same work the following list of spring flowers, showing how and when the various plants are propagated:—

CLASS I.—PLANTS RAISED FROM DIV. OF STOCK IN MARCH.

Arabis alpina flore pleno	Helleborus atrorubens, H.
Aubrietias, all varieties	caucasicus, and other
Erica carnea	varieties
E. c. alba	Iris foetidissima varie-
Festuca glauca	gata
	I. pallida variegata

CLASS II.—PLANTS RAISED FROM DIV. OF STOCK IN MAY.

Arabis alba	Phlox subulata Sprite
Alyssum saxatile nana	P. s. Vivid
Auriculas, alpine vars.	P. Newry Seedling.
Carex riparia variegata	Polyanthus, all vars.
Daisy, all vars.	Primroses, all vars.
Dononium austriacum	Scrophularia Scordonia
D. excelsum	variegata
Hemerocallis fulva varie-	Saxifraga Camposii
gata	S. cordifolia purpurea
Heuchera hispida	S. ligulata
syn. H. Richardsonii	S. moschata atropurpurea
Holcus mollis variegata	S. m. Guildford Seedling
Luzula sylvatica	S. m. Rhei
Phalaris arundinacea	S. purpurascens
variegata	Symphytum officinale
P. a. elegans	variegata
Phlox subulata Bright-	Violas, all vars.
ness	Violets, single and double
P. s. Nelsonii	Waldsteinia trifolia

CLASS III.—PLANTS RAISED FROM SEEDS SOWN IN THE YEAR PREVIOUS TO FLOWERING, WITH THE MONTH OF SOWING.

Alyssum saxatile nana	March
Daisy (Bellis perennis),	June
all vars. except Alice	June, first week
Erysimum compactum	June, first week
Golden Feather (Pyreth-	July
rum aureum)	March
Honesty, variegated	June
Myosotis alpestris Queen	"
Victoria	"
M. a. Royal Blue	"
M. dissitiflora	"
M. d. alba	"
Onopordon acanthum	March
Polyanthus, all vars.	Feb., 1st week, under glass
Primroses, all vars.	"
Stock, Empress Elizabeth	June, 1st week
Wallflower, Earliest of	"
All	May, 1st week
Wallflower, Phoenix	"
Wallflower, Belvoir Cas-	"
tle Yellow	June, 1st week
Wallflower, Dark Red	"
Wallflower, Double German	"
Wallflower, Ruby Gem	"
Wallflower, Salmon Queen	"

CLASS IV.—PLANTS RAISED FROM SEEDS SOWN TWO OR MORE YEARS BEFORE REQUIRED FOR FLOWERING.

Auriculas, alpine vars	March, 2 years before
Helleborus foetidus	August, 3 years before
H. atrorubens, H. cauca-	"
sicus, H. olympicus, and	"
others	"

CLASS V.—PLANTS RAISED FROM CUTTINGS UNDER GLASS IN MAY.

Arabis alpina flore pleno	Wallflower, double yellow
Phlox divaricata	Wallflower, double Har-
Wallflower, Double Dark	pur Crew
Red	

CLASS VI.—PLANTS RAISED FROM CUTTINGS IN SEPTEMBER.

Myosotis dissitiflora	Wallflower, double dark
M. d. alba	red
M. d. Dyeræ	Wallflower, double yellow
Violas, all vars.	Wallflower, double Har-
	pur Crew

THE TIMBER IN WESTMINSTER HALL.—

The causes of the decay in the wonderful timber roof of Westminster Hall, built by Richard II., have been found to be dry rot, "surface decay," whatever that may mean, and the ravages of the goat moth and of a small grub *Nestobium tessellatum*. Mr. WEDGWOOD BENN, in announcing the news that money is to be spent in making good the defects, stated that a committee of experts is engaged in considering the preparation of an effective insecticide to get rid of the agents of destruction. We do not wish to interfere with the work of the committee of experts, but would recommend them to use corrosive sublimate, which with a little ingenuity can be made to penetrate quite deeply into the burrows of "the insect."

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. COOKSON, Oakwood, Wylam-on-Tyne.

SPRAYING.—Most Cypripediums, the majority of Odontoglossums, and allied Orchids, luxuriate when they are well sprayed overhead, but the amount of syringing should be in accordance with the weather conditions. It is most important that spraying should be practised only when the foliage will become dry again before the temperature drops; it is not safe, until the end of May, to spray after about 1 p.m. Spraying will not only favour growth, but keep insect pests in check, and this is of the utmost importance. Vandas, Aërides, Saccolabiums, and other Orchids that are grown in the warmer houses should have their stems well moistened with the syringe early in the morning, and the spaces between the pots should also be damped two or three times daily when moisture evaporates rapidly. The plants are now in active growth, and humid conditions must be maintained about them.

PHAIO-CALANTHES.—From my experience it is best to re-pot these plants annually, and now is a suitable time to undertake the work. Remove the old compost entirely, and re-pot the plants in a compost composed of equal portions of turfy loam, peat and broken leaves, intermixed with sufficient sand, charcoal and broken crocks to render the material porous. Phaiocalanthes should be treated in practically the same manner as Calanthes, with the exception that, being semi-deciduous, little water is necessary during the whole of the resting period. It is best to treat the plants liberally until the flowering season is over, for they do not require anything like so severe a rest as Calanthes.

PHAIO-CYMBIDIUM CHARDWARDENSE.—This distinct and desirable plant will grow well if treated in every respect as advised for Phaius hybrids. The plants, as a rule, produce their growth later than Phaius, and should not be re-potted until the new growths are an inch or two long, when new roots develop. Shade the plants carefully from strong light after they are re-potted, and afford them only sufficient water to keep the shoots plump.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl Beauchamp, E.C.M.G., Madresfield Court, Worcestershire.

FLOWERING SHRUBS.—As soon as Jasminum nudiflorum, Forsythias, Ribes, and other early-flowering shrubs have finished blooming, thin out the weak spray growths, and shorten the leading branches fairly hard. The degree of pruning should be in accordance with the vigour of the plant, the object being to obtain strong breaks with stout lateral branches, for it is these that will give the finest flowers next season. There are many beautiful shrubs that have been introduced in recent years from China, and although many of them have not yet been tried in gardens, a great number have proved valuable additions. Taking the older kinds, the following represents a selection suitable for planting in groups or growing as single specimens in both large and small gardens. *Abutilon vitifolium*, *Abelia rupestris*, *Pyrus (Aronia) floribunda* (the leaves of this plant assume beautiful tints in the autumn), *Caryopteris Mastacanthus*, *Choisya ternata*, *Olearia Haastii*, *Veronica Traversii*, *V. salicifolia*, and the variety Autumn Glory; *Pyrus Malus Senebierkeri*, *Carpenteria californica*, *Halesia tetraptera*, *Tamarix hispida aestivalis*, and the newer varieties of both *Deutzia* and *Philadelphus*. A mass of the beautiful *Hydrangea arborescens grandiflora* or its variety *rosea* makes a good effect in the flower garden. *Veronicas*, too, although not quite hardy, are splendid summer bloomers. The plants may be lifted and placed in tubs to be sheltered in a cold pit during very severe weather; the finest varieties are *La Séduisante*, *Imperial Red*,

* Longmans, Green and Co. Price 5s.

Blue Gem, Purple Queen, Madame A. Véronique, and Hulkeana. Plants of *Romneya Coulteri* should be cut down annually to the ground level. If it is desired to increase the stock of this plant, now is a suitable time to take up the roots and divide them. This plant may easily be propagated from seed sown as soon as it is ripe.

HOLLIES AND EVERGREEN OAKS.—April and May are considered the best months for transplanting these evergreen trees. Fairly large specimens may be transplanted with success if precaution is taken to retain a good ball of earth about the roots. First prepare the stations so that the roots may be exposed for the least possible time. In planting ram the soil carefully on the under side of the ball and make it thoroughly firm all around the roots. When the planting is completed water the soil copiously so that the ground may settle closely, and finish with a mulch of animal manure. Hollies are specially adapted for growing as specimen plants on lawns; indeed, they never look better than when arranged in groups on grass. They should be planted sufficiently far apart to stand clear of each other, and even when employed in the mixed shrubbery it is advisable for Hollies to stand clear of all surrounding vegetation. The majority of Hollies form evenly-balanced specimens with very little attention to training or pruning, and, being evergreen, are attractive the whole year round. The little pruning required consists in shortening any extra vigorous shoots that would be likely to upset the proper shape and contour of the plant. A few of the best varieties and species are *Ilex Aquifolium*, *camelliaefolia*, *Hodginsii*, *Mundyi*, and *I. Wilsonii*. Perry's Weeping, Gold Queen, Gold King, Watereri, Shepherdii, Silver Hedgehog and *Ilex Pernyi*. Hollies are sometimes clipped into conical and other shapes as topiary objects, which I consider an abomination and an outrage upon nature. Holly hedges alone should be cut with shears.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

FIGS.—Trees with fruit ripening should be grown in a drier and more bracing atmosphere than hitherto, as these conditions cause the fruits to be better flavoured. In houses where the fruit is swelling, maintain a close, moist warm atmosphere. With fire heat the temperature should not exceed 70° at night, but when the sun shines it may rise to 90° or even 100° with benefit to the trees. Syringe frequently to keep down attacks of red spider. Pinch the points of the young shoots when they are about 3 inches long. Pot trees may be stopped even more closely. Top-dress Figs growing in pots with a mixture consisting of one-half cow or sheep manure, and one-half rich loam.

VINES.—The temperature may be lowered in early vineries when the berries have finished colouring; little fire heat need be employed excepting in dull, cloudy weather, and then merely to keep the atmosphere moving and sweet. Let there be a brisk heat with plenty of air in other houses where the bunches are beginning to colour. Maintain a bountiful supply of heat and moisture in houses in which vines are swelling off their crop. Thin the bunches and berries of other vines as may be required, and do the work thoroughly, as heavy cropping is one of the greatest evils in vine culture. Hasten the forcing of Lady Downe's and other late varieties, relying as much as possible on the sun's heat, and closing the house early in the afternoons of bright, sunny days. See that there is no lack of moisture in the houses, and keep the evaporating troughs filled with manure water.

MELONS.—The earliest fruits are approaching maturity, and the plants must be watered with extra care, as an excess of moisture would cause the fruits to crack. A mulch of manure from a spent Mushroom bed will prove beneficial and obviate frequent waterings. But the soil must never be allowed to become dry, for if this be permitted red spider will spread rapidly and spoil the fruit. It is a mistake to suppose that

Melons in their final stages require to be grown in a dry border or very hot atmosphere. Attend carefully to the work of tying and training the shoots of succession plants, and air the house freely on all favourable occasions. A steady but not gross growth is the most fruitful. Never shade from the brightest sunshine, but see that sufficient atmospheric moisture is present on such occasions. Plants growing in frames should be well covered up at night to equalise somewhat the fluctuating temperatures of day and night usually experienced at this time of the year. The moisture arising from the bed is usually more than sufficient for the full requirements of the plants, therefore do not syringe overhead too frequently nor during cloudy days. As soon as the lateral growths show fruit, pinch at one joint beyond it, and impregnate the strongest and largest blooms.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORFOLK, Eastwell Park, Kent.

YOUNG TREES.—In training very young trees, endeavour to build up well-furnished specimens, and as there will be plenty of space for extension, many more shoots can be retained than would be advisable in the case of older trees, but in neither case should the young shoots be trained so thickly as to cause overcrowding. Do not allow a central upright shoot to take the lead; this should always be removed at once, and the side-shoots trained in a regular fan-shape.

PEACH BLISTER OR LEAF CURL.—This disease is often a source of much trouble in the cultivation of Peaches out-of-doors, attacks following spells of cold, east winds, while growth is tender and therefore susceptible to injury. All infected leaves should be picked off and burnt, and the shoots cut back as far as they are infected; usually the trees will then grow out of the disease as the weather improves. After the fruits are set, spray the trees with an insecticide to destroy green fly and other insect pests.

MULCHING TRANSPLANTED FRUIT-TREES.—Following the heavy rains of March, we have experienced very dry weather for April, showers being rare. Heavy soils are cracking badly through drought, and trees that were planted late in the season may suffer injury unless measures are taken to counteract the drought. Break up the caked surface, and if a mulch of manure was not applied as recommended at the time of planting, spread a layer of light litter, such as manure from an old Mushroom bed, over the roots. If the drought is prolonged the transplanted trees may require watering. Syringings overhead in the afternoons of hot days are of great benefit, and may save many trees, which otherwise might fail to start into satisfactory growth.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowles Hall, Lancashire.

ANTHURIUM.—The plants have rooted in the fresh moss on the surface, and the stems may be partially severed just below the part where the moss was placed. In the course of a week the stem may be completely severed, and the plants potted afresh in a compost composed of equal parts of peat and very fibrous loam, from which the fine soil has been removed, three parts of Sphagnum-moss, a good sprinkling of lumpy charcoal, broken pot-sherds and sharp-sand. Make the material moderately firm, and surface the pots with a layer of clean moss. Soak the soil with water and syringe the plants freely.

EUPHORBIA (POINSETTIA) PULCHERRIMA.—The old plants, having been rested, are starting into growth afresh and will furnish a supply of cuttings. A good position in which to grow the plants is near to the front ventilators of a Peach house, or in a pit where the atmosphere is not too humid. Shoots 2 to 3 inches long should be taken off with a heel of old wood attached and inserted singly in 2-inch pots. Plunge the pots to their rims in coco-nut fibre in a propagating case with bottom heat of 80° to 85°. Shift the plants into 60-sized pots as soon as roots develop,

but replace in bottom heat for a few days and then grow them on a shelf near to the roof-glass. Young plants may also be raised from "eyes." Cut hard, well-ripened shoots into short pieces, each containing a good bud, and dibble them into pans filled with peaty soil and treat as for cuttings. Old plants not required for stock purposes may be cut down to two buds and encouraged to make strong shoots by syringing frequently. When the new growths are 1 inch long shake the old soil from the roots and put into receptacles just large enough to contain the roots and a little compost. Spraying overhead will afford sufficient moisture until the roots become active.

CALADIUM.—The roots of plants that were re-potted are re-established, and from now onwards thinner shading should be employed. Light tiffany may be spread over the roof-glass about midday, when the sun is strongest, and removed early in the afternoon. Close the house immediately after syringing, and promote a moist atmosphere by damping the floors and stagings between the pots. Specimens intended for use as table decorations should not be too closely shaded, as the light will bring out the bright colours, besides making the stems stiff and the leaves last longer in rooms. As the plants become pot-bound feed the roots with weak liquid manure. Remove all flower spikes as they appear.

VIOLETS.—Plants raised from cuttings rooted in frames last autumn are ready for planting on a border that is shaded by a wall or in the partial shade of trees. The ground should be well dug and enriched with soot and manure from a spent Mushroom bed. Ferk these materials into the soil and make the latter firm. Lift the plants carefully and set the double varieties 10 to 12 inches apart, but allow a space of 16 inches for singles. If the weather proves dry, water the plants and spray them daily at about 2 p.m. until the roots are re-established. Syringe the foliage with *Quassia* extract at intervals to keep red spider and green fly in check. Cuttings or runners may be taken from plants growing in pots or frames, and treated much in the same manner as autumn-rooted plants, but the latter are best for frame and pot culture, as they are earlier by several months.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

POTATOS.—A sharp outlook must be observed for pushing shoots of the later early varieties, and a little soil drawn over each shoot as a protection against morning frosts. If the ground can be safely stirred between the rows that also will afford a certain amount of protection, for the air-dried soil is, to a certain extent, proof against slight frosts.

CARROTS.—Long-rooted varieties may be sown in deeply-trenched ground, allowing rather more space than for stump-rooted sorts. Where there are annual losses from the Carrot maggot, try sowing deeply, leaving part of the drill to be filled with sand later. Some recommend sand that has been impregnated with petroleum as a protective, and one successful grower I knew used sulphur, not on the plants, but dug into the ground. The seeds are most easily manipulated when thoroughly mixed with dry soil or sand. Thin seeding, to obviate the seedlings growing close together, is a great advantage.

AUTUMN-GIANT CAULIFLOWER.—Unless this variety is afforded a long season of growth it is of very little value. Plants raised from seeds sown three months ago and growing in frames are sufficiently advanced to transplant. Deeply-trenched, very fertile soil is almost essential, and the plants should be set 3 feet by 3 feet apart. Lift the roots carefully in order to preserve as much ball as possible, and plant rather deeply. Choose the latter part of the afternoon for the operation, and water effectively; the next morning partially fill the holes in order to conserve the moisture. Should hot, dry weather follow, water must be applied till the plants are re-established or rain necessitates no further applications. Hoe the soil after waterings or rain, and this in time will fill the holes left at planting.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MAY 5—

Roy. Hort. Soc. Coms. meet. and Nat. Tulip Soc. Show. (Lecture at 3 p.m. on "The Value to Gardens of some of Mr. Wilson's Introductions from China.") Hort. Club dinner, 6.30 p.m. (Lecture on "Indian Garden Craft," by Mrs. Patrick Villiers-Stuart.) Scottish Hort. Assoc. meet.

WEDNESDAY, MAY 6—

B.G.A. Ex. Council meet.

THURSDAY, MAY 7—

Luncheon Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 50.3°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, April 29 (6 p.m.): Max. 70°. Min. 46°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, April 30 (10 a.m.): Bar. 29.5°; Temp. 55°. Weather—Dull.

PROVINCES, Wednesday, April 29; Max. 65°, Dorchester; Min. 40°, Darlington.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Hardy Bulbs and Tubers, at 12; Japanese Lilliums in cases, and miscellaneous Bulbs, at 3.30; Palms, Bays, and Greenhouse Plants, at 5. By Protheroe and Morris.

FRIDAY—

Orchids at Walserspool, Warrington, by order of W. Bolton, Esq. By Protheroe and Morris, at 1 o'clock.

Californian Plants.

A report in the *Transactions* of the third Annual Meeting of the California Association

of Nurserymen calls attention to the decorative value of Californian shrubs. Mr. Payne, the chairman of the committee which presented the report, enumerates the following as desirable garden subjects:—

Carpenteria californica, which grows successfully in Devonshire, Cornwall, and elsewhere in this country. The pure white flowers of the *Carpenteria* are well set off by the yellow Tree Poppy, *Dendromecon rigidum*, which grows from 4 to 8 feet and has graceful foliage.

Fremontia californica grows from 4 to 15 feet, and in early summer bears masses of golden yellow flowers, each 2 to 3 inches across. Though cultivated in Europe, it is not so well known as it deserves to be.

Common on the foothills of California is the Fuchsia-flowered *Ribes*, *R. speciosum*. It is propagated readily by cuttings and bears cardinal-red flowers about an inch long. It has the further merit that its leaves take a beautiful shade of red and brown in early summer. Other Californian *Ribes* of proved horticultural value are *R. tenuiflorum* (yellow flowered), *R. malvaceum* (pink) and *R. glutinosum*, with long racemes of bright pink flowers.

Trichostema lanatum is a deep blue-flowered plant for dry situations with rosemary-like foliage and with buds and flower-stems covered with a thick purple wool.

Of *Aretostaphylos*, *A. tomentosa* is the commonest in South California, *A. Manzanita*, one of the most beautiful of the shrubs of that part of the world, and *A. glauca* and *A. patula* are among other desirable species. *A. Manzanita* may, it appears, be propagated by layering.

The Smoke Tree (*Dalea spinosa*) is remarkable not only for its profuse dark blue Pea-shaped flowers, which are produced in May, but also on account of its variable size. Sometimes it forms a shrub 4 to 5 feet and at others it occurs as a tree 25 feet high. To its ashy grey colour this *Dalea* owes its popular name.

Chilopsis saligna is a Bignoniaceous shrub or small tree commonly known as the Desert Willow. Its leaves are deciduous and Willow-like, and its flowers are white and purple, blotched with yellow in the throat.

Of *Garryas*, besides *G. elliptica*, well known in Europe, mention is made of *G. Veitchii* Palmeri. *Eriodictyon tomentosum* and *E. Parryi* are interesting shrubby flowering plants found in dry situations, the former with grey woolly leaves and stems and violet-blue Heliotrope-like flowers, the latter with handsome foliage and long spikes of rich blue flowers.

Beside the typical *Rosa californica*, a variety (var. *glabrata*) occurs in the San Bernardino mountains, and its bright pink flowers are produced more lavishly than are those of the type.

Encelia californica, a common plant of the foothills, bears plentiful yellow Sunflower-like blossoms. *E. farinosa*, found on the edge of the desert, is a yet better plant—a compact bush with long-stemmed bright yellow flowers.

Berberis Nevinii is a rare shrub and forms a compact handsome bush with prickly foliage and long sprays of yellow flowers which appear in February.

The Malvaceae provide *Malvastrum fasciculatum*, a pretty shrub found in dry sandy places and bearing pale pink fragrant flowers in long wand-like branches. *Malvastrum Davidsonii* has larger flowers of a rare purple shade.

Fraxinus dipetala, the flowering Ash, is deciduous, grows from 5 to 15 feet, and bears light green foliage and white flowers.

Among other shrubs or shrubby plants which are recommended to Californians for cultivation are *Holodiscus discolor*, *Symphoricarpos mollis*, *Lotus glabra*, *Lepidospartum squamatum*, and *Salvia carduacea*, bearing a blossom as large as a croquet ball, with stems which grow out of the ball and bear other blossoms.

Roadside Beauty.

The powerful appeal made by Lord William Cecil in a recent letter to the *Times* will evoke the sympathy of all who love the natural and unique beauty of the English countryside. He speaks for Hertfordshire, and condemns the ruthless manner in which the roadside verge and bank are being denuded of tree and hedge and flower. Lord William arraigns the plant collector,

the up-to-date agriculturist and the county council.

We know not to what authority appeal must be made, but we join with Lord William Cecil in deploring this present destruction of what is most beautiful in the frequented parts of England.

It is evident that a commission of common-sense folk is required to investigate the present state of affairs. If such a commission were established, with powers to hear the several interested parties, rules for the guidance of well-meaning but necessarily ignorant county councils, road surveyors and the like might be laid down.

The road surveyor is, we fancy, one of the chief offenders. He, if he is enterprising, smears his main roads with tar, and by so doing lays down poison for the trees and shrubs which adjoin the road. Those responsible for the safety of the traffic of the road welcome the destruction or severe cutting back of hedges. They seek to make of lanes which embower peace straight cuts for people who are in a hurry to escape from the boredom which pursues their flying wheels as a pillar of cloud and a swift shadow.

The farmer is to blame likewise. After years of neglect of his hedgerows—neglect which has led to the growth of greedy thickets of Hawthorn and other hedge plants—he has awakened to the fact that these hedges, once the pride of the countryside, are cumberers of the ground. In his zeal for newly-discovered economies he is beginning to cut them down, forgetful of the fact that the hedges guard his ditches, protect his cattle from the wind and from contagion and from loss. The people who deal in plant pathology are also to blame. They discover that certain weeds may harbour the spores of pathogenic fungi which may infect the crops. They advocate, therefore, the clearing out of hedgerow plants, and the innocent must suffer with the guilty. The roadside is indicted as a harbourer of pestilent farm weeds, the seeds of which, borne by the wayside, invade the field. That this is so is true; but of the roadside herbs few are indeed the enemy of the farmer, and those who keep their own land clean have not much to fear from such invasions. It is not likely, with the present intricacy of local government, that much good will be done by appealing to this body or to that. What would do good would be a demonstration, on the part of those who have the land to spare, of the most economical and effective type of hedge and of the best mode of treatment of the grassy margin which makes our roadsides lovely. It is evident that an ideal hedge is one that roots deeply and does not plunder the cultivated ground or choke the ditches. It is also evident that Thistles and the like may be kept from seeding without destroying all the wild flowers which carpet the hedge banks. It may prove hard to strike a balance between the charms of beauty and utility, but it is not to be believed that raw and partial knowledge and uninformed zeal should be allowed to lay desolate the wild gardens of England which bloom by the waysides.

SPRING FLOWERS AT BELVOIR CASTLE, GRANTHAM, THE RESIDENCE OF THE DUKE OF RUTLAND.

Coloured Supplement.—The subject of the Coloured Plate to be published with the issue for next week is *Nepenthes ventricosa* and *N. x Sir W. T. Thibselton-Dyer*.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will take place in the Vincent Square Hall, Westminster, on Tuesday, the 5th inst. At three o'clock in the Lecture Room Mr. W. J. BEAN will deliver an address on "The Value to Gardens of Some of Mr. Wilson's Introductions from China."

HORTICULTURAL CLUB.—A house dinner of the Horticultural Club will take place on Tuesday, the 5th inst., at the Hotel Windsor, Victoria Street, Westminster, when Mrs. PATRICK VILLIERS-STUART (author of "Gardens of the Great Mughals") will deliver a lecture on "Indian Garden Craft," illustrated with lantern slides.

R.H.S. TULIP SHOW.—For the Royal Horticultural Society's meeting on the 5th inst. the Council invites collections of Darwin, May-flowering and cottage Tulips. The exhibits will be considered by a special jury, and the Council will make awards according to merit on their recommendation. At the same meeting six classes have been arranged by the Royal National Tulip Society, who will award prizes, and this Society will welcome exhibits of Tulip species to which suitable awards will be made if of sufficient merit.

R.H.S. GARDENS CLUB.—The annual outing of the members of the R.H.S. Gardens Club will take place on Saturday, July 13, when visits will be made to the Royal Botanic Gardens, Kew, and Mr. LEOPOLD DE ROTHSCHILD'S Gardens at Gunnersbury.

THE ORCHID COLLECTION OF THE LATE SIR J. J. TREVOR LAWRENCE.—When the late Sir J. J. TREVOR LAWRENCE, Bart., died an announcement was made that his well-known Orchid collection at Burford had been bequeathed to Lady LAWRENCE with an expression of his wish that such of the plants as were especially of botanical interest should be presented to the Royal Botanic Gardens, Kew. This gift has now been made to the national Orchid collection there, which has received from Lady LAWRENCE a large selection, consisting of 580 plants, belonging to 89 genera and representing 350 species, mainly, but by no means exclusively, of botanical interest. The character of the collection brought together by Sir Trevor at Burford during many years was a matter of general knowledge. It was singularly rich in rare and interesting species, owing to the fact that Sir Trevor at all times paid especial attention to whatever in the natural family was striking or unusual from a morphological standpoint, apart entirely from any decorative value which it might possess. The result of this was that the Burford collection was not only thoroughly representative of the usual showy species and hybrids, and on this account to be reckoned with in the horticultural world, but possessed examples of most of the cultivated genera, some of which are seldom met with, and for this reason was perhaps as important from the scientific as from the gardening standpoint. It included plants from almost every quarter of the globe, demanding the most diverse cultural treatment. The magnificent selection from the collection at Burford now transferred to Kew is rich in such genera as *Bulbophyllum*, *Cirrhopetalum*, *Pleurothallis*, *Maxillaria*, *Epidendrum*, *Eria*, *Angraecum*, *Dendrobium* and *Coelogyne*, and includes many species and a few genera not previously represented at Kew, some of these being rarely seen in cultivation. The genera not previously present in the Kew collection include *Trichoceros*, a high Andine genus very difficult to bring home alive and very difficult to cultivate afterwards; *Nasonia* and *Quekettia*, two small American genera; and *Stereochilus* and *Sigmatogyne*, from Northern India. The collection also includes a number of undetermined species

which have not yet flowered; in a few cases the genus to which these belong is still doubtful. These unknown plants have been derived from various sources; some of them are plants contributed to the Burford collection by Sir Trevor's son, Captain C. T. LAWRENCE, by whom they were obtained in West Africa.

ROYAL NATIONAL TULIP SOCIETY.—The annual exhibition of the National Tulip Society will be held during the spring show of the R.H.S. at Chelsea on May 20 and May 21, 1914.

PROFESSOR LEFROY.—We learn with much regret that Professor LEFROY met with a serious motor accident during the general meeting of the Association of Economic Biologists.

FIRE AT MESSRS. ROBINSON BROS.' WORKS, WEST BROMWICH.—A serious fire occurred at Messrs. ROBINSON BROS., LTD.'s premises, West Bromwich, on the 21st ult. This is the second outbreak within the last six months: the damage on this occasion is rather more extensive than on the last, and is estimated at between £1,200 and £1,500. Messrs. ROBINSON inform us there will be no delay in the despatch of plant foods and allied manufactures, as the fire occurred in the tar distillery and in no way affected the fertiliser and insecticide plant.

SALE AT DOVER HOUSE, ROEHAMPTON.—Owing to Mr. PIERPONT MORGAN'S intention to dispose of the Dover House Estate, it has been necessary to sell by auction most of the indoor plants, including the collection of Orchids. The sale took place on Tuesday and Wednesday in last week, the auctioneers being Messrs. PROTHEROE AND MORRIS. It is well known to most of our readers that Dover House has been remarkable for many years past for its splendid collections of plants, including Orchids, Carnations, Nerines and the fine foliage stove species. Consequently there was a good attendance at the sale, and excellent prices were realised for most of the lots. On the first day so many as five hundred lots were easily disposed of in three hours, and a similar number took but little more time. Amongst the purchasers there were representatives of the horticultural trade of this country and the Continent, and many amateurs, whilst considerable purchases were made on behalf of the Royal Gardens, Kew. It was frequently remarked that the various lots were presented for sale in extraordinarily fine condition by Mr. J. F. McLEOD, the steward and gardener, whose success as a cultivator in so many departments of the garden has made the name of Dover House familiar to all gardeners. For the present the gardens will be maintained as usual.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting of the Surveyors' Institution will be held in the Lecture Hall of the Institution on Monday, May 4, when the discussion on Mr. DAWBARN YOUNG'S paper, entitled "Comments on the Land Inquiry Committee's (Urban) Conclusions" will be resumed. The Council has accepted an invitation to hold the next country meeting at York on May 22 and 23.

PEAT FOR FRUIT TREES.—Experiments carried out in Germany, and reported by Mr. A. TRUELLE in *Revue de l'Hortic. Belge* (April 15, 1914), indicate that peat properly employed has a markedly favourable effect on the yield of fruit trees. The peat, which may be employed at the rate of 10 pounds to the square yard, should be divided finely and thoroughly soaked with water before being dug into and mixed with the soil in which the trees are to be planted.

RETIREMENT OF MR. J. F. WABY.—Mr. J. F. WABY, gardener at the Botanic Gardens, Georgetown, British Guiana, has retired from this post after thirty-five years' service in the Colony. Mr. WABY'S colonial experience commenced in

Trinidad in 1873, where he was appointed head gardener to the Botanic Gardens on the recommendation of Kew. In 1879 he was transferred to British Guiana, and has held the post of head gardener at the Botanic Gardens, Georgetown, to their very great advantage since that date. Mr. WABY'S retirement was made the occasion for the presentation of a testimonial by Professor J. B. HARRISON on behalf of the Board of Agriculture and the Staff of the department, and the Governor, in appreciation of the valuable services rendered to the Colony by Mr. WABY, has been pleased to appoint him an honorary member of the Board of Agriculture.

APPOINTMENT FROM KEW.—Mr. F. G. COUSINS, formerly a member of the gardening staff of the Royal Botanic Gardens, has been appointed a Sub-Inspector for the purposes of the Destructive Insects and Pests Acts under the Board of Agriculture and Fisheries.

PRESENTATIONS TO KEW.—We learn from the *Kew Bulletin* that Sir HARRY J. VEITCH has presented to the Royal Botanic Gardens, Kew, the important collection of Conifer cones which for many years has formed so interesting a feature of the Veitchian establishment at Chelsea. It consists of 170 species, including upwards of 60 Pines, 26 Firs, and a similar number of Spruces. The collection is of historical as well as of botanical interest, for, in the main, it comprises the specimens contributed by Messrs. Veitch's collectors in North and South America, China, Japan, and other countries between 1840 and the present date. The Hon. ARTHUR F. G. LEVESON-GOWER has presented two relics in the form of two keys of an old pattern, one of them inscribed "Botanic Garden V.R."; the other "Kitchen Garden No. 2, W.R." There is no doubt they were used during the period between the accession of William IV. in 1830 and the transference of the Botanic Garden at Kew to the public by Queen Victoria in 1840.

SOILING WILD OATS.—Our contemporary *Horticulture* states that the judge of the Malden (Mass.) Court has adopted the plan of sentencing juvenile offenders to serve for various terms at garden work. They will expiate their sowing of wild oats by the raising of cultivated varieties of vegetables and flowers.

HOME CORRESPONDENCE.

CYANIDING TO DESTROY MEALY BUG.—Mr. Fulton (p. 256) evidently does not approve of the use of sodium cyanide 130 per cent., but if it kills all insect pests what more would he wish? I shall, however, have much pleasure in putting his question to a qualified analytical chemist when the opportunity occurs. I am somewhat puzzled by Mr. Fulton's remarks about his intelligent amateur friend, who had evidently had some success with inferior materials, and yet found it necessary to treble the dose of cyanide—for a conservatory—when he had Mr. Fulton's stronger sulphuric. The result was "success" indeed, and is just what I would have expected, so far as can be judged from the details given. I have now obtained potassium cyanide of 98° to 100° strength, but must wait some time before I can use it, as all growth is now young and soft. I was indeed surprised to find that those who had made a study of cyaniding, and, to judge by their letters, could fumigate practically everything with impunity, should find it necessary to keep using the gas for so many years. I am certainly the first to admit that it is next to impossible to exterminate mealy bug in a house of mixed plants without injuring the plants likewise. Private letters from expert cyanidists confirm me in this belief. I am more or less in agreement with Mr. Fulton in his remarks that sealing over the holes and cracks is likely to be a doubtful success, and, in fact, I did not try it, but instead gave the vine rods a dressing with Arboline, which the makers strongly recommend for the destruction of mealy bug, and after using it I am convinced that they have good grounds for doing so. I used it in two houses that had been cyanided before and after cleaning, when all visible insects were killed, but shortly afterwards small bugs made their appearance. The Arboline was carefully applied with a painter's brush about six or eight weeks ago, and now when the vine shoots are being tied down we have not found more than two bugs in as many houses. Therefore if the dormant rods are well cleaned, and gone over twice, so that no hole or crevice escapes, I believe this specific will do much to rid us of the pest. Care should be taken not to exceed the maker's proportions as it is somewhat caustic. I applied the specific to a Peach tree trained against a back wall, when the flower buds were just showing colour, and thought for a time that the crop was ruined for the season, but I find there are enough fruits and to spare, and the tree clean and healthy. *A. Shakelton, Forde Abbey Gardens, Chard.*

THE LESSER NARCISSUS FLY (EUMERUS LUNULATUS) (see pp. 240, 272).—It is not desirable that in attempting to arrive at a really scientific conclusion the method known as deductive reasoning should lead to the substitution of purely imaginary surmises for specific facts, but this, it appears to me, is exactly what Mr. Bliss in his latest letter (p. 272) has been doing. Having to support the "scavenger" theory Mr. Bliss has to marshal his so-called facts, and so has to kill—on paper—the bulb of Glory of Noordwyk in the year 1913; and, to effect this, the assistance of Fusarium is called in. But there was and is no Fusarium in the whole border in which this bulb was situated. In fact I have only had that fungus in two bulbs, both acquired last season and since lifted, and, with the adjacent soil, burned in a greenhouse stove, and so Fusarium is "out of it." The bulb in question was the only defaulter in a section of the border containing some hundreds of bulbs. And next, Mr. Bliss remarks that the grubs found in this bulb "must have come from eggs laid in the second or a still later brood." But, except to support the "scavenger" theory, why? Every bulb in my special borders is carefully inspected, not once but many times when the "dates of flowering" are being taken, and in every case where there appears to be the slightest sign of questionable health a "danger signal" is set up in the shape of a label on a wire well up over the bed. There was no sign of indisposition about this particular bulb, and when the foliage had died down and had been removed the whole beds were very carefully raked over. And yet the Eumerus fly is supposed to

have dropped its eggs into an imaginary hole, or on the raked earth just above the bulb. Clever fly! It seems to me that where so little is really known about the matter there is a better guide than mere surmise, and that is the guidance furnished by what is called analogy, and in this case, as the Merodon and Eumerus are so closely allied, it appears the more likely that the latter does what the former unquestionably does—namely, deposit its eggs in the lower portion of the foliage of a living and perfectly healthy bulb. But all this would not be worth discussing were it not that the idea that the fly simply does scavenger work may lead some people to defer the remedy until the contrary is proved. We can possess our minds in patience until the life history of the fly has been worked out on other than speculative lines, and several are now engaged upon this work, as I know from the number of applications which I have received for specimens of the grub. To the last enquiry I had to reply "stock exhausted for the season," but I hear that Mr. Chittenden at Wisley would like a few more grubs. Can Mr. Bliss supply some from his obviously well-stocked menagerie? *Charles E. Shea.*

CRICKETS IN PLANT HOUSES (see p. 292).—As a further means of ridding a house of crickets I would recommend the use of the "V. T. II." slug traps, which I see are advertised in the last issue of *Gardeners' Chronicle*. It may interest readers generally to know that last year I used them with splendid results for slugs, but it was quite by accident that I found they were so effective for crickets. I put some in a cucumber frame for the purpose of trapping slugs, and was agreeably surprised next day to find that one of them contained no fewer than 67 crickets. They were baited with bran, and the bottom filled with salt water as advised. As we were greatly troubled with crickets this discovery has made the "V. T. H." traps very valuable to me. I do not think the vendors even realise their value in this connection, for I have not seen it mentioned in their advertisements or leaflets. We have now practically got rid of crickets, and this year no harm has been done by them, and we very seldom hear any chirping. *William F. Rowles, Ellisfield Manor Gardens, Basingstoke.*

GLADIOLUS MASONIORUM.—In your report of the current issue of the *Botanical Magazine*, tab. 8,548, it is stated that *Gladiolus Masoniorum* had withstood 11° of frost at Kew. The plant was sent to Mr. Lynch, and it was at Cambridge, and not at Kew, that this plant was experimented with, as to its hardiness. *G. H. Banks, The Botanic Garden, Cambridge.*

WASPS.—I have been informed by a gardener in this locality that he caught more than 50 queen wasps last week by hanging up some glass jam jars in the pear trees. The jars were half-filled with ale and sugar. Every queen wasp caught now will mean one nest fewer later. *Jas. Hussey, Rydens Grove, Hershams, Walton-on-Thames, April 22.*

—On Monday, April 27, I discovered under an old Rose bush in these gardens a wasp nest, complete with comb and live grub about half developed. It would be most interesting to know if any of your readers have ever had a similar experience on or before this date. *Salcey Lawn Gardens, Northampton.*

[See reply to W. Baker in the "Answers to Correspondents" column, p. 308.—EDS.]

RAINFALL.—The amount of rainfall on the West Coast of Scotland for the month of February was 11.21 inches, and for March 5.96 inches. Rain fell on twenty-seven days in February, and twenty-five days in March. Our gauge is about 40 feet above the sea level. *George Haigh, Barcaldine Gardens, Ledaig, Argyllshire.*

OFFSETS OF HIPPEASTRUM.—In your notice of my lecture on "Hippeastrums" (see p. 270), your correspondent refers to my remark that I could not remember having seen an offset produced by a bulb which was itself an offset; but the experience of others might be different. Apropos of this, Mr. E. F. Hazelton informed me after the lecture that at Knowsley he grew a variety named Albert Edward which produced offsets freely from bulbs which were themselves offsets. *C. R. Fielder.*

SOCIETIES.

NATIONAL ROSE.

SPRING SHOW AT WESTMINSTER.

APRIL 23.—The second spring show of the above society, which was held at Vincent Square on St. George's Day, was a splendid success. The hall was filled with a beautiful array of Roses. Long before noon great queues of ticket-holders were waiting to enter, and within a few minutes of opening the doors the hall was crowded, and remained so until an unusually late hour. As compared with the first spring show there were double the number of entries, and, except in the class for new Roses, the quality of the blooms was superior. In every case the blooms were as fresh and attractive at seven o'clock as when they were first staged. A welcome feature of the show was the strong competition in the amateurs' classes.

There was no Gold Medal Rose at this show, but a Gold Medal was awarded to Messrs. Wm. PAUL AND SON for their fine group of pot Roses.

The Hon. Secretary, Mr. Ed. Mawley, received valuable assistance from Mr. Frank Reader and the other members of the R.H.S. staff.

NURSERYMEN'S CLASSES.

GROUPS OF ROSES.

In Class 1, which provided for pot Roses arranged in a space of 250 square feet, there were six exhibits, and the Society's Gold Medal was awarded to Messrs. WILLIAM PAUL AND SON, Waltham Cross, for a superlative display. Huge pillars, seven to eight feet high, of Excelsa, Rowena, Blush Rambler, Tausendschön and its white variety, all heavily laden with fresh blooms, rose just clear of a charming profusion of such dwarf varieties as Liberty, Richmond, Mme. C. Chambard, Madame C. Lutaud, Prince de Bulgarie, Mrs. C. Hunter, Sunburst, and Juliet. The composition of this group, the high quality of the blooms, and the taste displayed in arrangement all combined to make it a magnificent exhibit.

The Silver-gilt Medal group of Messrs. PAUL AND SON, Cheshunt, contained as a central feature charming plants of the old favourite yellow Banksian Rose. These were surrounded by pillars and weeping standards of such Wichuraiana hybrids as Minnehaha, Excelsa, Lady Godiva, and White Dorothy, rising at intervals above closely arranged dwarf plants. The appropriately named variety Magnolia, bearing plenty of semi-double sulphur-yellow blooms, adjoining Cherry Ripe and J. B. Clark, met with a full meed of admiration. Other sorts shown in good condition were Edward Mawley, Rayon d'Or, Mme. Second Weber, Sunburst, and Mme. Victor Verdier.

The Silver Medal was awarded to Messrs. HOBBIES, LTD., East Dereham, for a group of good plants bearing admirable blooms, but arranged a trifle too formally. An extra prize was awarded Messrs. Wm. CURBUSH AND SONS, Highgate, for a very pretty effort composed solely of Wichuraiana and Polyantha Roses. This was so attractive that a class for a group of these varieties, with a clause enjoining lightness of arrangement, would be well worth the Society's consideration.

The class for a group of Pot and Cut Roses placed on the floor in a space of 100 square feet was not so well contested. There were three entries, and the 1st prize exhibit shown by Messrs. A. and J. ALLEN, Norwich, was composed of such magnificent Roses as to completely overshadow those of their competitors. The plants in the premier group bore a surprising profusion of blooms of very rich colours, and were arranged with much skill and good taste. The taller plants were of such varieties as American Pillar, Sodenia, Paul Ploton, Minnehaha, and Lady Gay. In the centre of the groundwork of dwarfs massed vases of gloriously coloured Sunburst contrasted finely with the pink of Juliet and the rich crimson of Edward Mawley. Mr. GEORGE PRINCE, Oxford, won the 2nd prize, and his group was particularly noteworthy for a large central mass of Mme. Edouard Herriot, and well filled stands of Mme. Jean Dupuy, W. R. Smith, White Maman Cochet, and Frau Karl Druschki. The 3rd prize was awarded to

Messrs. BEN R. CANT AND SONS, Colchester, whose collection was composed chiefly of graceful *Wichuriana* varieties.

There were only two exhibits of Cut Roses arranged on the staging, and here Messrs. G. MOUNT AND SONS, Canterbury, won the 1st prize with a memorable display. The background of very tall cut sprays of *Tausendschön* provided a fitting frame for the splendid vases of Richmond, Mrs. J. Laing, Mrs. A. R. Waddell, Lady Hillingdon, Dorothy Page Roberts, and similar varieties. Messrs. B. R. CANT AND SONS, who were awarded the 2nd prize, had a beautiful vase of Fortune's Yellow and a splendid stand of *Rose du Barri*.

ROSES IN POTS.

Messrs. PAUL AND SON, Cheshunt, were unopposed in the class for 12 Standard Roses, and these were so good as to make us wish for more. The clean-stemmed, well-balanced specimens of such sorts as *Caroline Testout*, *Hugh Dickson*, *Mrs. John Laing*, and *Fisher Holmes* were all that could be desired.

Messrs. PAUL AND SON were also the only exhibitors of 9 Pillar Roses, and were awarded the 1st prize for equally fine plants of this class of Rose, and they won the 1st prize in the class for 9 Weeping Standards with splendidly grown specimens, of which *Ethel*, *Eisenach*, *Hiawatha*, *Excelsa*, and *Dorothy Perkins* were exceedingly floriferous. Mr. C. TURNER, Slough, was awarded the 2nd prize.

The exhibits of 50 Dwarf Polyantha Roses in 6 inch pots were not so attractive: the exhibitors for the most part contented themselves with showing the minimum 5 varieties. The best collection was that of Messrs. WM. PAUL AND SON, who had very good plants of *Orleans*, *Yvonne Rabier*, *Jessie* and *Edward VII.*: 2nd, Mr. C. TURNER, whose chief sorts were *Mignonette* and *Gloire des Polyantha*; 3rd, Messrs. PAUL AND SON, Cheshunt.

EXHIBITION BLOOMS.

The champion class in this section was for 36 blooms in not fewer than 24 varieties and not more than 3 blooms of any one variety. The chief honour was won by Messrs. FRANK CANT AND Co., Colchester, who had a splendid collection of fresh blooms in which the H.T. varieties largely predominated. The varieties were *Caroline Testout*, *Frau Karl Druschki* (2), *Gustav Grunerwald* (2), *Peerless*, *White Killarney*, *Mrs. Muir MacKean*, *Maréchal Niel* (2), *George Dickson* (3), *Mrs. M. Kennedy*, *Ulrich Brunner*, *Lady Ursula*, *Marquise Litta*, *Mrs. Foley Hobbs* (3), *Mrs. J. Laing*, *Mrs. T. Roosevelt*, *William Shean*, *Sumburst* (3), *Mrs. George Shawyer*, *Hugh Dickson* (3), *Lady Alice Stanley*, *Souv. de Gustave Prat*, *Gloire de Chédane-Guinoisseau*, *Mrs. Herbert Stevens*, *Frau M. Möller*, and *Lady Ursula*: 2nd, Messrs. B. R. CANT AND SONS, Colchester, who showed rather smaller blooms, which, like those in the champion exhibit, were very fresh and of good substance; 3rd, Messrs. G. and W. BURCH.

Messrs. A. DICKSON AND SONS had no competitor in the class for 18 blooms, and received the 1st prize for a magnificent collection, which included *Mrs. R. D. McClure*, *Mrs. Cornwallis West*, *H. V. Machin* and *Mrs. Foley Hobbs*.

The two exhibits of 12 blooms of *Maréchal Niel* were splendid, and it would be difficult to imagine better specimens of this deliciously fragrant yellow Rose. There was very little to choose between the exhibits of Mr. A. R. GODWIN, Maidstone, and Mr. C. BENT, Irlam, Manchester, but the former was sufficiently the better to win the 1st prize.

The class for 12 blooms of any other variety contained in Messrs. A. DICKSON AND SONS' blooms of *Mrs. Foley Hobbs* the best exhibit in the show; Mr. ELISHA HICKS won the 2nd prize with fine blooms of *Mrs. George Norwood*, a very fragrant, pink H.T. Rose; 3rd, Messrs. G. and W. BURCH, who showed *Florence Pemberton*.

ROSES IN VASES.

Messrs. G. MOUNT AND SONS were the only exhibitors of 12 Distinct Varieties shown in vases, and were awarded the 1st prize.

Mr. WILL TAYLOR, Hampton, was awarded the 1st prize for 6 Distinct Varieties.

The Baskets of Cut Roses were only moderate in quality. Messrs. G. MOUNT AND SONS were

disqualified for a technical infringement of the schedule, and were awarded a special prize.

NEW SEEDLING ROSES.

SILVER-GILT MEDAL.

Rose Princess Mary (H.T.) (see fig. 135).—A charming single Rose of rich ~~carmine-crimson~~ colour suffused with scarlet. The petals are broad and overlap, making a bold round flower in which the small group of golden stamens intensify the rich colouring. The blooms were fully 4 inches across, and the raiser states that when grown in the open they average quite 6 inches. (Shown by Mr. ELISHA HICKS).

as *Mme. Edouard Herriot*, and, like that variety, is semi-double, but the petals being rounded at the ends make a more globular flower. (Shown by Mr. HUGH DICKSON.)

Nine Stems of New Roses.—Messrs. ALEX. DICKSON AND SONS were alone in this class, which requires varieties first put into commerce since the beginning of 1911. They were awarded the 1st prize for very good blooms of *St. Helena*, *Mevrouw Dora van Tets*, *Coronation*, *Mrs. Cornwallis West*, *Lady Greenall*, *Duchess of Westminster*, *Lady Dunleath*, *Mrs. R. D. McClure* and *Elli Hartmann*.

Nine Pots of New Roses.—Messrs. A. DICKSON AND SONS were also awarded the 1st prize in this

FIG. 134.—ROSE AUTUMN TINTS: FLOWERS PINK, SUFFUSED WITH ORANGE-SALMON. (National Rose Society's Card of Commendation on April 23, 1914, see below.)

CARDS OF COMMENDATION.

R. Mrs. S. T. Wright (T.).—A medium-sized bloom set on long, stiff stems of bright, shining leaves. The fragrant flowers are orange-buff, with apricot-coloured centres. (Shown by Messrs. ALEX. DICKSON AND SONS.)

R. Autumn Tints (H.T.) (see fig. 134). An exceedingly attractive variety rather suggestive of the popular Lyons Rose—the deep flesh-pink is suffused with a sheen of orange-salmon. The blooms are large and well formed, and the foliage is good. (Shown by Messrs. B. R. CANT AND SONS.)

R. Prince Charming (H.T.).—This beautifully coloured Rose is of the same elusive shades

class, where their best varieties were *Sachsen gruss*, *Coronation* and *George Dickson*.

AMATEURS' CLASSES.

There was no exhibit in this section of a group of Pot Roses placed on the floor, but the groups of Cut Roses arranged on staging space of 5ft. by 5ft. were exceedingly attractive, and the 1st prize group of Mr. E. GORDON CLARK, Leatherhead, contained a good variety. The Polyanthas were especially meritorious, as also were the vases of *Sumburst* and *Frau Karl Druschki*; 2nd, Mr. E. J. HOLLAND, Sutton, who had fine examples of *Mrs. W. J. Grant*, *Lady Fair* and *Mme. M. Lucie Souper*; 3rd, Mr. H. R. DARTINGTON, Putter, Bar.

Only two exhibitors contested the class for 12 Blooms in Exhibition Boxes, and here Mr. J. HOLLAND, showing beautiful specimens of such varieties as Wm. Shean, Nita Weldon, and Caroline Testout, won the 1st prize; 2nd, Mr. G. A. HAMMOND, Burgess Hill, who had a fine bloom of Souv. de P. Notting, and could not have been many points behind the former.

The 6 Blooms in not fewer than four varieties were only a moderate class, and the chief prize fell to Mr. F. H. FIELDGATE, Colchester, in whose stand a wonderfully fine bloom of Lyons Rose attracted admiration; 2nd, Mr. P. T. DAVIS, Burgess Hill.

Six Blooms of the variety Wm. Shean, shown by Mr. E. J. HOLLAND, were decidedly the best in the Any Variety Class, where the 2nd prize

the bright red Richmond, a variety which was used by two other exhibitors. Shown also by Mrs. E. WILLIAMSON, Canterbury, it won the 1st prize in the class for a Vase of Cut Roses, where Mrs. COURTENAY PAGE was 2nd with Sunburst.

MIDLAND DAFFODIL.

APRIL 23, 24.—The sixteenth annual exhibition of Daffodils held under the auspices of the above society on these dates at the Botanical Gardens, Edgbaston, pleasantly situated on the west side of Birmingham, was a great success. Nearly all the best raisers and growers of Daffodils were represented, and many new varieties of high quality were exhibited.

to work satisfactorily. Owing to the death of Mr. Robert Sydenham, founder of the society, the annual dinner, which always formed such a pleasant adjunct to the Birmingham gathering, was omitted on the present occasion. At an informal meeting held at the Grand Hotel on the evening of the first day of the show Mr. P. D. Williams (president) in the chair, supported by a representative gathering of members, it was unanimously decided to have a dinner in 1915, but with a shorter toast list than formerly. The rest of the evening will then be given up to Daffodil chat.

The non-competitive exhibits from the Rev. G. H. ENGLEHEART, Mr. A. M. WILSON, Mr. W. T. WARE, Messrs. BARR AND SONS, Messrs. J. R. PEARSON AND SONS, and others contained many novelties.

DAFFODILS.

CUT FLOWERS (OPEN CLASSES).

The biggest class was one for a collection of fifty varieties, representing so far as possible the sections into which the Daffodil is divided. One vase of each variety containing three stems with Daffodil foliage for effect was required. There were six exhibits. The 1st prize was won by Messrs. CARTWRIGHT AND GOODWIN, Kidderminster, whose flowers consisted largely of the small flowered varieties, were of surprisingly good quality, beautifully fresh, and effectively staged. The principal varieties exhibited were The Doctor, Cornelia, Mrs. H. J. Veitch, Acme, Horace, Kestral, Matthew Arnold, Mrs. Robert Sydenham, Moorfoot, Dorothy Kingsmill, Mrs. Ernest Crawford, Loch Fyne, Silver Swan, Dorothy, Cassiopoea, White Rose, Aquarius, Whitewell, Felspar, and Jaune à Merveille. 2nd, Mr. C. BOURNE, Bletchley, who also relied very largely upon small flowered varieties, had splendid examples of Elgar, Barcarolle, Kingsley, Incognita, Moonbeam, Queen of the North, and Seville. 3rd, Rev. JOSEPH JACOB, Whitchurch.

The next class was one for a decorative exhibit of cut Narcissi, arranged on a space of 9 feet by 4 feet against a wall. Exhibitors had the option of introducing any kind or style of decoration, but it was a *sine qua non* that all flower stems should be in water, wet sand, or moss. The schedule imposed no restriction as to the number of varieties, quantity, or quality of flowers, as the class was judged from a purely decorative point. The 1st prize was won by Mr. C. BOURNE—last year's winner—whose flowers, mostly of the poeticus type, were displayed in dark basket-covered vases, jars, and tall Bamboo stands interspersed with plants of *Cyperus alternifolius* and Ferns against a brown-draped background. A square "knee-cap" piece of brown material occupied the forefront of the group, which, instead of adding to, detracted from the general effect. The 2nd prize was awarded to the Rev. JOSEPH JACOB for a well conceived and artistically arranged group. But for the inclusion of a bright yellow muslin base the effect would have been most pleasing, and in all probability the awards would have been reversed. The centre piece consisted of a large vase set on a pedestal beautifully decorated with pale coloured Daffodils and sprays of Asparagus. 3rd, J. A. KENRICK, Esq., Harborne (gr. Mr. R. Usher).

It was compulsory to exhibit three stems of each variety in the following eleven classes:— In a class for six varieties of yellow Trumpet Daffodils Messrs. E. H. KRELAGE AND SON, Haarlem, won 1st prize with unusually large, substantial flowers of Hope of Holland and five unnamed seedlings. 2nd, Mr. JOHN POPE, King's Norton, who had excellent blooms of Mrs. H. J. Veitch. 3rd, Mr. J. MALLENDER, Scrooby.

In a similar class, but for white Trumpet Daffodils, Messrs. E. H. KRELAGE AND SON were again placed 1st with delightfully fresh, shapely specimens which unfortunately contained a decidedly yellow Trumpet seedling No. 87. After a protest had been upheld Mr. J. MALLENDER, who had been awarded 2nd prize, was given the leading position with meritorious flowers of Dromina, Marotz, St. Elmo, Catherine H. Pugham, Alina Skelton, and Sybil Forster.

Mr. JOHN POPE and Mr. J. MALLENDER were the only exhibitors in a class for six varieties

FIG. 135.—ROSE PRINCESS MARY: COLOUR, CARMINE CRIMSON WITH A SUFFUSION OF SCARLET. (Awarded the National Rose Society's Silver-gilt Medal on April 23, 1914; see p. 303.)

was won by Mr. F. H. FIELDGATE with a good half dozen of Frau Karl Druschki.

The exhibits of 5 Distinct Varieties in Vases were very meritorious, and the 1st prize collection of Mr. G. A. HAMMOND included very good vases of Mrs. W. J. Grant and Mme. Melanie Souper; 2nd, Mr. F. H. FIELDGATE.

DECORATIVE CLASSES.

There were nine tables decorated with Roses. The 1st prize arrangement consisted of the saffron-yellow H.T. Rose Melody, with Rose foliage and a few trails of Asparagus plumosus, by Mrs. COURTENAY PAGE, Enfield, was exceedingly good. Mrs. ROBINSON, Carshalton, won the 2nd prize with a pleasing table of Joseph Hill; and Mrs. TISDALL, Woodford Green, was 3rd with

Competition in many of the classes was better than at any of the society's previous exhibitions, and considering the very hot weather experienced for about eight to ten days prior to the show the all-round quality of the flowers was surprisingly good. Owing to the trying season there were fewer large Trumpet varieties than usual, but there was a great increase in the number of smaller flowered white or light coloured varieties.

The weather on the first day of the show was hot, but on the second day the conditions were more favourable. The Floral Committee recommended awards to three varieties of Daffodils, descriptions of which will be found below. The R.H.S. (1913) classification of Daffodils was adopted at this show, and the experiment seemed

of bicolor Trumpet Daffodils. The first-named competitor led with handsome, well set-up flowers of Weardale Perfection, and fine unnamed seedlings.

The only exhibit of six varieties of yellow-shaded Incomparabilis Daffodils came from Mr. C. BOURNE, who showed Redcap, Solitare, Gloria Mundi, Cœur de Lion, Marina, and Giraffe.

In a corresponding class to the last-named, but with flowers having a white or whitish perianth and self-yellow, red stained or red cup, the Rev. JOSEPH JACOB led with exquisite flowers of The President, Warden, Lady Moore, Sophy Primrose, Lady Jellicoe, and Whitewell. 2nd, Mr. C. BOURNE, whose best flowers were Whitewell, Dosoris, and Victory.

The best exhibit of six varieties of Barrii Daffodils came from the last-named exhibitor, who had refined flowers of Yellow Pet, Occident, Castile, Jaspas, Merryman, and Torchlight. 2nd, Mr. W. A. WATTS, St. Asaph, who showed Occident and a promising seedling numbered 668.

In a companion class to the last-named, but with flowers possessing a white or whitish perianth and self-yellow, red stained or red cup, Mr. C. BOURNE again scored with Ethelbert, Imperialist, Queen of Hearts, Red Chief, Egret and Cossack. 2nd, The Rev. JOSEPH JACOB, who had Whisper and a very good unnamed seedling.

The 1st prize in a class for twelve varieties of Leedsii Daffodils was won by the last-named exhibitor, whose best flowers were Easter, Norah Pearson, H. C. Bowles, Hon. Mrs. Francklin, Sister, Penguin, and Endurance. The 2nd prize, which came from Mr. C. BOURNE, contained good flowers of Queen of the North, Easter, Hypatia, St. Olaf, and Bianca.

The class for three varieties of Triandrus hybrids contained many flowers of superior merit. The 1st prize was awarded to Mr. F. H. CHAPMAN, who had choice specimens of White Witch, Minstrel, and Alabaster. 2nd, Rev. JOSEPH JACOB, whose best variety was Winter Snow. 3rd, Mr. W. A. WATTS.

Although there were only two entries in the class for six varieties of Tazetta and Tazetta hybrid Daffodils, the quality of the flowers in each case was superb, especially in Messrs. CARTWRIGHT AND GOODWIN'S 1st prize stand, which included Klondyke, Orient, Jaune à Merveille, Aspasia, Sunset, and Admiration. The other exhibitor was the Rev. JOSEPH JACOB.

The flowers in the class for nine varieties of True poeticus exhibited by Mr. E. M. CROSFIELD, Cossington, Bridgwater, were the best poeticus varieties in the show. The flowers were particularly large and substantial, borne on very strong stems and well displayed. The varieties exhibited were Ashgard, Glaucus, Sarchedon, Ring Dove, Lovelace, Athenian, Iliad, Socrates, and Sonata. 2nd, Mr. F. H. CHAPMAN. 3rd, Mr. C. BOURNE.

SINGLE BLOOM CLASSES (OPEN).

Mr. R. BRUCE WAITE, Harborne, had the best yellow Trumpet Daffodil in Monarch, as well as the leading Tazetta or Tazetta hybrid Daffodil in Jaune à Merveille. The winning flower in a class for a white Trumpet Daffodil was a handsome specimen of the new Mrs. Ernest Krelage, exhibited by Messrs. E. H. KRELAGE AND SON. The best bicolor Trumpet Daffodil was Diogenes. It came from Mrs. RIDLEY, of Wincanton, who also excelled in a class for a Barrii Daffodil possessing a white or whitish perianth with Ceres. Mr. A. M. WILSON showed the best Incomparabilis bloom (Division 2A) as well as the best Leedsii variety. From Mr. E. M. CROSFIELD came the most perfect Incomparabilis Daffodil with a white or whitish perianth in Aladdin. The same exhibitor also had the best Jonquilla hybrid in Zephyr. Mr. W. WELCHMAN'S King Cyrus was adjudged the best yellow-shaded Barrii Daffodil (Division 3A). The best Poeticus variety was Raeburn, a large, round-petalled flower exhibited by Mr. C. BOURNE.

SEEDLINGS AND NEW VARIETIES.

Seedlings and new varieties were largely and well shown. The Bourne Challenge Cup perpetuates the name of a gentleman who worked assiduously for many years to popularise the Daffodil both as a garden and exhibition flower.

On the present occasion it was offered for twelve varieties raised by the exhibitor. The Cup, which is held for one year, is accompanied by a Gold Medal, and was again won by the redoubtable Mr. E. M. CROSFIELD, who beat four contestants with a magnificent stand of the following varieties:—Orbit, Dell, Ring Dove, 192s, Charles Surface, Touchstone, Dulce, Orb, Sybarite, 451s, Anchorite, and Mowgli. 2nd, Mr. P. D. WILLIAMS, St. Keverne. 3rd, Mr. W. WELCHMAN, Wisbech.

Mr. A. M. WILSON excelled in a class for six varieties of seedling Daffodils raised by the exhibitor and not yet in commerce. He showed Avalon, Melanie, 339, 660, 65B, and 478. 2nd, Mr. C. H. CAVE, Mangotsfield. 3rd, Mr. JOHN POPE.

In a similar but smaller class to the last there were seven entries. 1st, Dr. N. Y. LOWER, Presteign, with three choice unnamed varieties; 2nd, Mr. C. L. ADAMS, Wolverhampton; 3rd, Rev. T. BUNCOMBE.

The next class was reserved for novices who had never won a 1st prize for seedlings (single blooms excepted). The schedule required three varieties raised by the exhibitor and not in commerce. The 1st prize was a Silver Vase given by Mr. Christopher Bourne, and was won by the Rev. T. BUNCOMBE with a pleasing set of flowers all under numbers; 2nd, Mr. C. L. ADAMS; 3rd, Mr. J. PADLEY, Worksop.

The Cartwright Challenge Cup was offered for twelve varieties that have not been in commerce more than four years. A Gold Medal also accompanied the Cup. The only competitor was Mr. E. M. CROSFIELD, who has secured this award on previous occasions, and showed exquisite blooms of Caesar, Royal Lady, Mowgli, Orb, Dell, Aladdin, Dulce, Charles Surface, Orbit, Sarchedon, Ring Dove, and Anchorite.

In a smaller class for six varieties of new Daffodils there were five competitors. 1st, Mr. C. BOURNE, with shapely flowers of Merryman, 427, Queen of Hearts, Symphony, Golden Idol, and Raeburn; 2nd, Rev. JOSEPH JACOB; 3rd, Messrs. CARTWRIGHT AND GOODWIN.

There were three first-rate exhibits in a class for three seedling Daffodils. 1st, Dr. N. Y. LOWER, with beautifully fresh flowers; 2nd, Mr. J. PADLEY; 3rd, Rev. T. BUNCOMBE.

For the Herbert Chapman Poeticus Trophy, six Poeticus varieties that have not been in commerce more than four years, including at least one variety not yet in commerce, Mr. A. M. WILSON was placed 1st with exquisite flowers of Madrigal, Bret Harte, 709, 695, 439, and 706; 2nd, Mr. F. H. CHAPMAN; 3rd, Mr. C. BOURNE.

The Walter Ware Challenge Cup, offered for six varieties of Triandrus hybrids, was won by Mr. E. M. CROSFIELD with unnamed varieties; 2nd, Mr. W. A. WATTS.

A piece of plate offered as 1st prize in a class for three varieties of Daffodils, nine stems of each, was won by Mr. F. H. CHAPMAN; 2nd, Mr. JOHN POPE.

A new class was provided for six varieties of white or nearly white Trumpet Daffodils that have not been in commerce more than four years. The 1st prize consisted of a Silver Challenge Cup to be won three times (not necessarily in succession) before becoming the absolute property of the winner, and 20s. 1st, Messrs. E. H. KRELAGE AND SON, whose flowers of Mrs. Ernest Krelage and five unnamed varieties were much admired; 2nd, Mr. W. A. WATTS; 3rd, Mr. J. MALLENDER.

AMATEURS' CLASSES.

Competition in the amateur section was very encouraging, there being nine exhibits in the class for twenty-four varieties. 1st, Mr. S. F. STAFFURTH, Boston, for a very representative collection, which included good quality flowers of Ethelbert, White Lady, Cassandra, Pilgrim, Barcarolle, Noble, Gloria Mundi, Cygnet, Madame de Graaff, Beacon, and Whitewell; 2nd, Mr. E. H. WOOD, Ludlow, whose flowers of Occident, Horace, and White Lady were particularly good; 3rd, Rev. T. BUNCOMBE.

Mr. S. F. STAFFURTH also won 1st prizes in classes for (1) three varieties of Incomparabilis Daffodils (Division 2A); (2) three varieties of Incomparabilis Daffodils (Division 2B); (3) three varieties of Barrii Daffodils (Division 3A);

and (4) three varieties of Barrii Daffodils (Division 3B).

Mr. R. BRUCE WAITE was successful in classes for (1) nine varieties of Trumpet Daffodils, (2) six varieties of Leedsii Daffodils, and (3) three varieties of Tazetta and Tazetta hybrid Daffodils.

The Rev. T. BUNCOMBE had the best of ten exhibits in a class for six varieties of true Poeticus varieties, closely followed by Mr. S. F. STAFFURTH.

MESSRS. SYDENHAM, LTD., offered prizes for twelve varieties of Daffodils, three stems of each, no variety to cost more than 5s. per dozen bulbs. The 1st prize was awarded to Mr. A. TAYLOR, Olton, whose exhibit included creditable flowers of Leonie, Horner, Glory of Leiden, Grandee, Princess Mary, and Albatross. The same exhibitor also showed the best three varieties of double Daffodils.

Mr. R. S. WAITE beat seven contestants in a class for an arrangement of cut Daffodils on a circular table $2\frac{1}{2}$ feet in diameter.

The Birmingham Botanical and Horticultural Society's Medals were awarded as follows:—Classes 3 to 27: Silver Medal, won by Mr. C. BOURNE with 84 points; Bronze Medal by the Rev. JOSEPH JACOB with 52 points. Classes 14 to 27 and 28 to 38: Silver Medal, won by Mr. E. M. CROSFIELD with 62 points; Bronze Medal by Mr. A. M. WILSON with 49 points. Classes 14 to 27 and 39 to 50: Silver Medal won by Mr. R. BRUCE WAITE with 78 points; Bronze Medal by Mr. S. F. STAFFURTH with 62 points.

The Barr Vase was won by Mr. R. BRUCE WAITE with 80 points.

AWARDS OF MERIT.

Narcissus Idris (for show).—A charming Incomparabilis variety, with a broad stout perianth and a rich deep yellow crown or cup. Exhibited by Mr. W. A. WATTS, St. Asaph.

Narcissus Mrs. Ernst Krelage (for show).—A lovely white Trumpet flower of great size and substance. Exhibited by Messrs. E. H. KRELAGE AND SON, Haarlem.

Narcissus Evangeline.—A Leedsii variety of great purity, with large, smooth, overlapping petals. Exhibited by Mr. H. D. PHILLIPS, Olton.

ASSOCIATION OF ECONOMIC BIOLOGISTS

APRIL 17 and 18.—The general meeting of this association was held at the Royal College of Science on the above dates under the presidency of Professor Newstead, F.R.S.

Among the papers read at the meeting the following are of special interest to horticulturists:

OBSERVATIONS ON THE WINTER STAGE OF THE AMERICAN GOOSEBERRY MILDEW.

By Mr. E. S. SALMON.

The author drew attention to the need for investigations to determine the extent to which the winter fruiting stage (perithecial stage) is responsible for the first spring outbreak of the disease. Examination of perithecia in winter shows that many are dead or have failed to mature; such perithecia cannot be the cause of the spring outbreak. Perithecia which were formed earlier in the season do become mature. To prevent infection from this source bushes should be topped as early as possible in autumn, and the pieces should be burned.

In the course of the discussion on Mr. SALMON'S paper, Dr. Pethybridge stated that he had observed the bursting of perithecia in winter.

CELERY LEAF SPOT.

By Mr. F. J. CHITTENDEN.

The author gave an account of the results of his experiments in planting "seed" infected with the leaf-spot fungus (*Septoria petroselinii*) in sterilised soil. The seedlings produced from infected "seed" showed the presence of the disease in the cotyledons; hence it is to be inferred that the seedlings become infected by spores present on the "seed," i.e., on the fruit coats.

Dr. Pethybridge, in commenting on the paper, observed that 90 per cent. of the Celery "seed" in the market is infected with *Septoria*, that

American "seed" is often free from this infection, but that American varieties of Celery are not regarded as suitable for cultivation in this country. It happens not infrequently that although spores are present on the "seed" they are unable to germinate, and Dr. Pethybridge said that in two-year-old seed the spores would probably have all lost their infective powers. Unfortunately the germination of Celery seed falls considerably in its second year.

Treatment with 0.3 per cent. formalin or with hydrogen peroxide (10 or 20 volumes) for three hours is sufficient to kill the fungus without injury to the seed. Spraying with Bordeaux mixture checks the disease.

BACTERIAL ROT OF CELERY.

By Mr. H. WORMALD.

A soft, pulpy rot which sometimes affects Celery is found by Mr. WORMALD to be due—in part, at least—to a bacterium, *B. apivorus*. It is a wound parasite, and gains access to the leaf-stalk through abrasions caused by slugs, etc. Excessive moisture appears to favour the disease. Plants affected should be destroyed.

POTATO DISEASES.

By Mr. A. S. HORNE.

The author pointed out that much uncertainty exists as to the mode in which outbreaks of late blight (*Phytophthora infestans*) originates each year. Another subject which requires investigation is the cause of the high percentage of diseased tubers in crops the foliage of which has apparently been free from the disease.

Extended observations on leaf-blotch (leaf curl) indicate that this disease is not to be attributed to attack either by fungi or insects.

Seedling plants of the variety of the Potato President have been investigated by Mr. Horne and Professor Lefroy, and from their observations it appears that the malady is to be ascribed to environmental conditions proving unfavourable to the normal development of the plant.

THE ORGANISM OF POTATO SCAB.

By H. T. GUSSOW.

The author concludes that the organism responsible for scab is a member of the genus *Actinomyces* of the Schizomycetes (Bacteria).

BROWN OAK.

By Professor PERCY GROOM.

The author concludes that brown Oak, which occurs sometimes in common British Oak, is due to the action of a mould, *Penicillium glaucum*.

THE GOLF GREEN FLY.

By Mr. A. W. WESTROP.

A description was given of a fly, as yet unnamed, which has destroyed the Grass on putting greens of certain golf courses. The larvae form galls on the grass, and so far attempts to destroy the fly by means of insecticides have not proved successful. Smooth-stalked but not rough-stalked meadow Grass is attacked.

THE PHYTOPATHOLOGICAL CONFERENCE.

By Mr. A. G. L. ROGERS.

It was decided by the delegates at the Conference recently held at Rome to accept the principle of a convention, and the three following points were agreed to with little difficulty:—

1. Plants coming from a country with a certificate of health need not of necessity be separately examined.

2. All diseases to be specified.

3. Consignments should not be detained by the Customs at entry.

In the event of an actual convention the States concerned would be pledged to an official inspection of all gardens, nurseries, etc., offering plants for sale, and to give certificates; also, would undertake to establish one or more research stations.

It was unanimously decided to leave to each country the making of its list of scheduled pests; but some general rules were agreed upon. Thus it was prescribed that the list should be as restricted as possible, no pests should be included in cases where the hosts are absent from the country, and all pests which have been widely distributed in a country for years would be omitted. Pests included would be those easily conveyed by

living plants or parts of plants, epidemic in character, and destructive to the commercial value of the plant. In accepting the principle of a convention a step forward has been taken in the direction of international action, and unity of action based on a system of mutual trust.

KINGSBRIDGE DAFFODIL AND SPRING FLOWER.

APRIL 14.—The Spring Show of the Kingsbridge Horticultural Society was held in the Market Hall.

The 1st class in the schedule was for a collection of fifteen varieties of Daffodils, and the 1st prize was won by Mrs. GAGE-HODGE, with a very creditable exhibit. The same exhibitor was also successful in gaining the 1st prize for nine varieties of Trumpet Daffodils, six varieties of *N. incomparabilis*, three varieties of *N. Leedsii*, and a single bloom of *N. Barrii*. For nine varieties of Daffodils, the 1st prize was awarded to Mrs. G. M. YONGE. Mrs. D. M. YONGE gained the 1st prizes for three varieties of Poetaz and the special prize offered by Messrs. Cartwright and Goodwin for nine varieties of Daffodils; Mrs. SOLTAN-SYMONS was placed 1st in the class for three varieties of *N. poeticus*, and in those for a single bloom of Trumpet Daffodil and of *N. poeticus* respectively. The same competitor also won the 1st prizes for six varieties of spring flowers and for twelve varieties of flowering shrubs. The Rev. H. A. BRKS obtained several 1st prizes, namely, for six bunches of Polyanthus, for twelve varieties of flowering shrubs, for three plants of double Primroses, for three pots of Tulips, and for three pots of Lily-of-the-Valley. Other prizewinners were Miss CLARICE VIVIAN, Mr. C. J. ADIE, Lord ASH-COMBE, and Lady L. GREENE.

FOREIGN CORRESPONDENCE.

BRUSSELS WITLOOF CHICORY.

I SEND a sample of what we call Brussels Witloof. Few gardeners in England appear to know the merits of this fine vegetable. Witloof is a much improved variety of the common Chicory, and when properly cooked is equal to Seakale, whilst it is much less costly to grow. I fear gardeners are apt to be too conservative and to look askance at anything that has not been developed in England. I believe that Witloof might be grown as well in England as in Belgium and Holland. *H. Rabjohn, Twickel Castle Gardens, Delden, Holland.* [The Witloof was very delicious when cooked as Seakale. An article on its cultivation in Belgium was published in the *Gardeners' Chronicle*, July 5, 1913, p. 6.—Eds.]

NOTES FROM SOUTHERN ITALY.

The spring here has been characterised by heavy hailstorms and rain; during March it rained every day. The leaves of the Tulips are mottled with white, and the earlier species will bear but few seeds. The finest of the Tulips (*T. praestans*) is now in flower, bearing three blossoms on a stalk. *T. ingens*, *T. Micheliana*, *T. Fosteriana*, *T. montana*, *T. Dammani*, and the lovely white *T. primulina* are also flowering well. I have a plant which I received from Holland under the name of *Tulipa orphanidea*, but I find it is not the true species, which bears yellow flowers with a dark purple base; it is nothing but the dull-red *T. Haageana*, a native of Palestine.

IRISES.—Under the name of *Iris Van Houttii* I received a plant some years ago from a friend. The standards are blue and the falls dark blue with a black blade; probably it is *I. iberica* × *olbiensis*. It grows here very well; the flowers are not so large as those of *I. iberica*, but are well shaped. Can anyone enlighten me as to its origin? The earlier Flag Irises are now at their best. The dwarf *I. rubromarginata* makes a lovely rockery plant.

Euphorbia biglandulosa and *E. Characias* are in flower. The latter species resembles *E. Wulfenii*, but is earlier in flowering. The blossoms are dark green with red ovaries.

Arisaema ringens and *Epidendrum macranthum* (pure white), and the Japanese purple variety are doing well on a shady rockery among plants of *Woodwardia*, *Cyrtomium*, *Pteris*, *Asplenium* and *Aspidium*.

Nymphaea vomerensis has just opened two fine flowers. It is a hybrid between *N. alba* and *N. pygmaea himalayensis*, and is the first (and latest) of my Water Lilies, which I grow only in tubs.

Calanthe viscolor nucerense is now quite over. It was in flower for over a month in an ordinary cool house, and the Japanese *Calanthes* are coming on. *Willy Müller, Naples, April, 1914*

DEBATING SOCIETIES.

NORTH OF SCOTLAND HORTICULTURAL AND ARBORICULTURAL.—A very large audience was present at the last monthly meeting of the North of Scotland Horticultural and Arboricultural Association, held in the Botanical Classroom, Aberdeen University, to hear a lecture on school gardening by Mr. Lewis Gavin, head master, Drumwhinle School, Arnage, Mr. Gavin gave a résumé of the methods employed by teachers who give instruction in school gardening. He suggested a course somewhat after these lines:—From the age of twelve to fourteen the pupil might be exercised in digging, trenching, and manuring, and instructed in all methods of obtaining perfect tilth. His knowledge of the commoner kinds of garden produce, their requirements, and the best methods to employ to produce perfect specimens would be practically gained, while the aesthetic side of his nature would be developed in a love for harmonious colour effects in the massing of annual, biennial and herbaceous plants. He should be given an adequate training in English—a training that would fit the pupil to write logically and grammatically. Alongside of this his training in mathematics, mainly in the calculations of area and in content or bulk, in questions for commercial dealings, buying and selling, would go hand-in-hand. In his fourteenth year the pupil's knowledge of plant life, of soil formation, of the disintegrating effects of frosts and rains, leading him up to the chemistry of the soil, should be developed.

CROYDON AND DISTRICT HORTICULTURAL.

At the meeting of this society held on March 17, Mr. W. Swan, of Thorncote Gardens, Staines, gave a lecture on "Bush Fruits," dealing with Apples, Black, Red, and White Currants, Raspberries, Gooseberries, Loganberries, and Blackberries.

BRITISH GARDENERS' (Leamington Branch).

A meeting of the Leamington Branch of the B. G. A. was held on March 28, when the general secretary, Mr. Cyril Harding, gave a lecture on "The Evolution of Horticulture."

BRISTOL AND DISTRICT GARDENERS'.

A meeting of this association was held on March 28, when Dr. Smith presided. The lecturer for the evening was Mr. Ayres, who read a paper on "Vine Culture." The meeting held on the 9th ult., Mr. J. Bastin presiding, was of especial interest, being the occasion of the annual visit of the Bristol Amateur Horticultural Society. Mr. Webber, secretary of the visiting society, read a paper, entitled "Ethics of Horticulture," questions being asked and satisfactorily answered by the lecturer, who was accorded a hearty vote of thanks. The prizes offered by Dr. Shaw, for two pots of *Schizanthus*, were won by Messrs. Hayball, Bird, and Spry, in this order.

WARGRAVE GARDENERS'.

At the last meeting of this association, Mr. E. Feltham (of Messrs. Waterer, Sons, and Crisp, Ltd.), delivered a lecture on "The Cultivation of Certain Alpines." He referred to more than twenty varieties, gave cultural directions, and explained how each could be used to the best advantage.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS'.

At the meeting of this society, held on the 6th ult., Mr. B. Pugh, of Messrs. Carter and Co., Raynes Park, delivered a lecture on "Hardy Flowers from Seed for Town Gardens," illustrated with numerous handpainted lantern-slides. The lecturer stated that hardy border flowers raised from seed are best grown in boxes and transplanted when the seedlings become established. The boxes should contain soil of poor quality mixed with a little decayed cocoon fibre. *Antirrhinum*, *Ageratum*, *Carnations*, *Dahlias*, *Cantebury Bells*, *Nemesias*, *Poppies*, *Nasturtiums*, *Phlox Drummondii*, *Scabious* and *Verbenas*—in fact, all herbaceous border plants would, he contended, flourish in either town or country gardens, provided the soil was well dressed with lime and enriched with plenty of manure.

DUMFRIES AND GALLOWAY GARDENERS'.

The closing meeting of the session was held on the 25th ult., Mr. S. Arnott in the chair. Mr. Oliver, Drumlanrig Castle Gardens, Dumfriesshire, gave a lecture on the Royal Gardens, Kew. Mr. Oliver, who was a member of the Kew staff for four years, gave an admirable account of the national gardens, and the lecture was illustrated by a number of lantern views.

MARKETS.

COVENT GARDEN, April 29.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ebs.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices. Includes items like Anemone St. Brigid, Arums (Richardias), Carnations, Daffodils, Enchiridion, Gardenias, Gladioli, Iris, Ixias, Lilium auratum, Mignonette, Narcissus, etc.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and ferns and their prices. Includes items like Adiantum Fern, Agrostis (Fairy Grass), Asparagus plumosus, Carnation foliage, etc.

Foreign Flower Market.

Table listing foreign flowers and their prices. Includes items like Anemone fulgens, Lilac white, etc.

REMARKS.—Prices for white flowers have advanced considerably. White Stock from the South is arriving in much smaller quantities, and this has sent up the price of Pelargoniums. A few white Azaleas remain in the market, but the quality is getting very poor, although the prices are doubled this week. Carnations are highly priced, especially white ones. Lilium Harrisonii and Richardias are much cheaper, but Lily-of-the-Valley is getting short, and prices may advance during the next few days. The white flowers chiefly used for making-up purposes are in greater demand. There is nothing to take the place of Stock or Pelargoniums at present, which is the cause of the sudden rise in price. Stephanotis, Eucharis, and Gardenia are more plentiful. Sweet Peas are coming to hand in better

condition, but pink varieties are still short. Spanish Iris is more plentiful, and is selling better. Gladioli are still very poor; the best variety is Peach Blossom. Iceland Poppies are the latest arrival, but these are limited to a few bunches, and are soon bought up. There is still a glut of all Roses, and prices remain exceptionally low. The consignments of flowers from Guernsey chiefly consist of St. Brigid Anemones, Irises, Ixias, Darwin Tulips, and Gladioli. Darwin Tulips from this quarter are poor, compared with those from English growers. There is an abundant supply of Forget-me-Not, White Gypsophila and Asparagus plumosus, A. Sprengeri, Smilax, and Adiantum Fern. French Myrtle, French Fern, and several other varieties of hardy foliage are now on sale. Single Daffodils are practically finished; a few English-grown Grande Monarch and a few boxes of Emperor from Scotland are the only sorts arriving. The first consignment of Double White Narcissus should come to hand next week. Buyers are daily making inquiries for this useful variety.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various plants in pots and their prices. Includes items like Aralia Sieboldii, Araucaria excelsa, Asparagus plumosus, Azalea, Bionia mecmastigma, Cacti, Cineraria, Cocos Weddeliana, Croton, Draecena, Erica persoluta, Ferns, etc.

REMARKS.—Business in this department continues very brisk. Genistas and Azaleas are practically finished, but Ericas are increasing in variety. Both white and coloured Stocks are arriving in good condition. White and pink Hydrangeas are more plentiful, but blue ones are very scarce. Polyanthus and Rambler Roses are making a bright show, and are selling more freely. There is a good supply of all flowering plants.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices. Includes items like Apples, Bananas, Grape Fruit, Lemons, Lychees, Mangos, Melons, Nuts, Oranges, Peaches, Pears, etc.

REMARKS.—Apples from Colonial sources are a shorter supply; the s.s. "Osterley" brought about 7,000 cases. The most attractive varieties are from Western Australia. There are also fewer Pears from the Cape. Shipments this week from the Cape, per s.s. "Edinburgh Castle," consisted of about 22,000 packages, the bulk being of Grapes. The new crop of Muscat of Alexandria and Black Hamburg Grapes from home growers is available. English Peaches are now arriving in the market. Strawberries are sent in larger quantities daily. There is a fairly plentiful supply of Melons and Figs. Green Gooseberries are on sale, and Cherries are arriving from the Continent. Tropical Fruits on sale include Custard Apples, Loquat, Granadillas (Passion fruit), red and yellow-coloured Bananas, Pineapples, Oranges, Lemons, and Grape Fruit. Tomatos from English growers are an increasing quantity daily; whilst Marrows, Carrots, Asparagus, Turnips, Beans, Peas, Mushrooms, Cucumbers, Seakale (natural grown), Cabbage, Broccoli, and New Potatoes are all plentiful. Egyptian Onions are very dear.—E. H. R., Covent Garden, April 29, 1914.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices. Includes items like Artichokes, Beans, Beetroot, Carrots, Cabbages, Cauliflowers, Celery, Chicory, Cucumbers, Endive, Garlic, Horseradish, Lettuce, Leeks, Marrows, etc.

Old Potatoes.

Table listing old potato varieties and their prices. Includes items like Blacklands, Dunbar-Red soil, Grey soil, etc.

New Potatoes.

Table listing new potato varieties and their prices. Includes items like Jersey, Lishon, etc.

REMARKS.—Trade is not quite so good for Old Potatoes, but consignments are equal to the demand. Several varieties of New Potatoes are arriving, and these will make a considerable difference in the sale of old tubers. New Potatoes will be cheaper almost daily for a few weeks.—Edward J. Newborn, Covent Garden and St. Pancras, April 29, 1914.

GARDENING APPOINTMENTS.

Mr. T. A. Stewart, for the past 7 years at Dover House, Roxhampton, formerly as Orchid Grower, latterly as Foreman, as Gardener to J. PIERPONT MORGAN Esq., at Wall Hall, Watford, Herts.
Mr. A. B. Macgregor, formerly of Dover House Gardens, Lambton Castle, Clarendon, and St. Osyth's Priory, as Superintendent on the estate of J. PIERPONT MORGAN, Esq., at Glenoave, Long Island, U.S.A.
Mr. John Finnie, for the past 12½ years Gardener at Summerhill, Shandon, Dumbartonshire, as Gardener to H. PHILLIPS, Esq., Stobo Castle, Peeblesshire. [Thanks for 2s. 6d. for R.G.O.F. box.—Ebs.]

NEW INVENTION.

MODEL FOR TEACHING TRENCHING AND DIGGING OPERATIONS.
HORTICULTURAL instructors will welcome a class-room aid in teaching double digging and trenching, devised by Mr. W. H. North, instructor under the L.C.C. For the complex method of lettering the several spits he has substituted the use of wood blocks 6 inches by 1 inch

by 1 inch, painted in different colours to represent the different spits. The top spit is painted black, the middle spit red, and the bottom spit is unpainted. By this mode of demonstration students easily learn an operation, in itself simple, but difficult to grasp from a many-lettered diagram.

Obituary.

CHARLES M'IVER.—Mr. Charles M'iver, formerly gardener at Lincluden House, Dumfries, died at Annan on the 20th ult. at the age of 70. He was a skilful gardener and was specially successful in the cultivation of stove and greenhouse plants.

ANEMOPSIS CALIFORNICA: *E. B. Anderson.* This plant belongs to the Natural Order Piperaceae, and has no resemblance to *Anemopsis macrophylla*, a member of the Ranunculaceae. Its proper name is *Houttuynia californica*, and it will succeed in any light, rich soil in a moist, partially-shaded situation.

BANANA FRUITING IN A CONSERVATORY: *E. G.* The temperatures you mention—60° at night and 75° to 80° in the day—are suitable for winter, but somewhat low for the present season, which might account for the fruits failing to swell at the base of the bunch. When the temperature is too low it is often difficult to get the lower parts of the bunches to swell or finish; especially if the deficiency has occurred when the fruits are first forming, in which case they often decay away altogether. Another frequent cause of failure is an excess of moisture in the house during the winter. The roots are very fleshy, and the plants should be kept rather dry from November to March. You do not state whether your specimens are planted out or growing in tubs. There is always a certain amount of difficulty in finishing off the fruits if planted out, as the absence of root restriction makes them difficult to feed. As you cannot maintain a higher day temperature than 75°, it would be well to keep the house rather close; but overhead damping should be sparingly done, and only after bright sunshine. It is probably a question entirely of temperature, not of food. There was a good deal of dull, chilly weather in March and April, when the fruits were developing; we should not advise you to give an excessive amount of food now, as it would only tend to aggravate the evil by forcing into unnatural growth the few fruits which have formed. If you could employ more heat moisture could be increased in proportion, and the plants of *Musa Cavendishii* would fruit in twelve months. Your night temperature is, if anything, rather low for plants at this time in bearing, but if the fruits set you should, with care, obtain a good bunch.

CUCUMBER STEM DISEASED: *A. McK.* The plants are affected with canker, and any that show signs of the disease should be removed at once as they invariably die, and may spread the disease. This is a notifiable disease according to the regulations of the Board of Agriculture and Fisheries.

CYANIDING VINES IN FULL GROWTH: *E. P. S.* It will not be safe to use cyanide in a vinery in summer until the main leaves on each shoot are firm in texture, otherwise damage may be done. A cold evening should be chosen for the operation, and the flowering plants in pots should be removed from the house. The surfaces inside the vinery must be quite dry, and full ventilation permitted until you are ready to cyanide. This is to prevent any condensation of moisture on the foliage before the gas has generated. The quantities to use are 3 oz. cyanide, 5 oz. sulphuric acid, and 8 oz. water per 1,000 cubic feet contents. Do not fumigate when the vines are in bloom. If the condi-

tions in the vinery are perfect probably only the tips of sub-laterals or very soft young leaves may be injured, but this is of little consequence so long as the main foliage on the full length of each shoot is unharmed. The house should be opened one hour after the operation and a little air left on all night. You must employ earthenware receptacles. The acid would destroy the zinc soup plates.

FIGS DISEASED: *H. R.* The Figs are attacked by a fungus—*Botrytis*. The disease is favoured by moist conditions and extremes of day and night temperature, the latter causing moisture to be deposited by condensation. Keep the house drier and ventilate freely.

FUNGUS ON A SAVIN TREE: *W. K.* The jelly-like fungus called *Gymnosporangium juniperinum* is a parasite, and as its mycelium is perennial in the affected branches these should be removed. The fungus is not likely to have killed the tree.

GARDENING EMPLOYMENT IN AMERICA: *Enchantress.* The hours for gardeners and assistants in U.S.A. are from seven to five. A night fireman is kept during the fall and winter months, and at other times the assistants take turns in looking after the furnace. As to Sunday duty, turns are taken according to the number of hands employed on the place. The average hours in commercial establishments are as a rule from seven to six. Gardeners settling in America are advised to work for at least two years before assuming a head position, as the methods of growing, propagating, and management of plants in the United States differ much from the practices that obtain in this country. Several kinds of vegetables are grown there which are not cultivated here.

KENIA BELMOREANA: *J. C.* The red points on the Palm stem are the fruits of a fungus called *Nectria sanguinea*.

NAMES OF PLANTS: *T. S.* White variety of *Begonia semperflorens*.—*J. A. 1*, *Kerria japonica flore pleno*; *2*, *Forsythia suspensa*; *3*, *Pyrus floribunda*; *4*, *Aucuba japonica* (male form); *5*, *A. japonica* (female form); *6*, *Skinmija japonica*; *7*, *Sprekelia formosissima*.—*G. H., Curry.* *1*, *Cytisus monspesulanus*; *2*, *Amelanchier canadensis*; *3*, not recognised, send when in flower; *4*, *Elaeagnus pungens variegata*; *5*, *Euonymus pendulus*; *6*, *Akebia lobata*.—*C. S.* The fungus is a *Morel*—*Morchella conica*, one of our rarer species.—*G. H. H. S.* *Oxalis cernua*.—*W. K. T. L.* *Dendrobium thysiflorum* and *Fritillaria Melegris*.—*Busford.* *Rhododendron ciliatum*.—*J. L. H. 1*, *Salvia* sp., specimen too scrappy to identify; *2*, *Cardamine pratensis flore pleno*; *3*, *Macrotomia echioides*; *4*, *Saxifraga cordifolia*; *5*, *Epimedium pinnatum*.—*G. D. A. 1*, *Ruscus aculeatus*; *2*, *Daphne Laureola*; *3*, *Ribes alpinum*; *4*, *Lathyrus cyaneus*; *5*, *Alyssum saxatile*; *6*, *Phlox Stellaria* var. *ilacina*; *7*, *Helianthemum vulgare* var. *cupressus*; *8*, *Anemone Pulsatilla*; *9*, *Arenaria balearica*; *10*, *Adiantum cuneatum elegans*; *11*, *Pelargonium "Clorinda"*; *12*, *Adiantum formosum*.—*F. R. D. 1*, *Rosa Banksiae*; *2*, *Lithospermum purpureo-coeruleum*; *3*, *Sedum rupestre*; *4*, *S. praealtum*; *5*, *Spiraea Thunbergii*; *6*, *S. cantonensis*.—*A. R.* *Senecio (Kleninia) articulata*.

PEACHES DISCOLOURED: *T. D. S.* The appearance of the fruits at first suggested Peach mildew, but a critical examination reveals no trace of disease. An excess of water at the roots would cause the rusty appearance, but whether the plants have been over-watered or not only those on the spot can determine.

PEACHES DROPPING: *J. S.* The trouble is due to there being a lack of moisture at the root when the fruit was setting.

RASPBERRY CANES DISCOLOURED: *C. T.* The trouble is due to some external cause, and not to disease.

SCHIZANTHUS UNHEALTHY: *A. E. U.* The trouble is not due to disease; the culture has been wrong in some detail, and only those on the spot could say in what respect you have erred.

SEEDS: *H. S. E.* The seeds are of Ivy, and have passed through the intestines of birds.

STREPTOCARPUS: *Foreman, Surrey.* If the plants are required to flower by May 17 next it would be as well to pick off any flowers that are open now. Those that develop in a fortnight or three weeks before the date mentioned will provide a good crop, although they may be a little longer in very dull weather. Plants of *Streptocarpus* remain in flower for a long time, especially when kept growing freely by judicious feeding. They can be retarded by lowering the temperature and shading in bright weather.

SULPHURIC ACID FOR ROSE MILDEW: *W. L. J.* The proportions are sulphuric acid 1 part to 1,000 parts water. The acid should be pure, as the commercial product contains impurities that are injurious to tender foliage.

TULIPS FAILING: *W. B.* The plants are attacked by *Botrytis* the fungus that causes "Lily" disease. Burn any of the plants that are badly crippled, and, when lifting the others for storing, dust them with sulphur and quicklime in equal proportions.

VERONICA HULKEANA: *A. T. H.* The plants are attacked by a fungus, *Peronospora grisea*. Spray them at intervals of four days with a solution of liver of sulphur—1 oz. in 4 gallons water—until the mildew disappears.

VINE SHOOT DYING: *Serp., Henley.* The border contains too much organic manure, which has prevented the roots from starting as early as they should have done. Unless in a very weak condition Vines always produce fresh shoots before roots, consequently they have to depend, for a time, on material stored up in the buds and stems during the previous season. When the border is in an unsuitable state, and there is irregularity in the growths, the stronger buds contain the larger amount of this stored material, and might hold out till the delayed root formation has commenced, while the weaker shoots, having exhausted the stores in their immediate vicinity, might collapse. As you have a strong and apparently healthy shoot at the base of one of the Vines you should train that up to form a new rod, for the older one will probably be of little use. If there is any mulching material on the surface of the border it should be removed, and you might apply wood ash or potash salts and bone dust or basic slag, with a sprinkling of lime, during the present growing season, but no nitrogenous matter.

WASPS: *W. Baker.* Thanks for nest of wasps received. April 19 is not particularly early for wasps to begin nesting, but, of course, the weather of March and April regulates the re-appearance of the queens after hibernation, a warm spell bringing them out any time during April, or even during late March, if the warmth is great enough and prolonged for a day or two. Every queen killed at this season means the absence of anything from 5,000 to 50,000 wasps later on, and it would probably pay fruit-growers and others interested in any district where the queens appear exceptionally numerous to provide a small fund from which to pay a penny or twopenny reward to school children for every queen wasp brought in before the middle of May. Someone capable of recognising the queens should be the judge, in order that early workers do not get paid for, as has happened on some occasions. It is just as well to remember, however, that wasps consume vast numbers of flies of all kinds, and unless they are exceptionally numerous it is not desirable to attempt their extermination, lest a worse plague befall. Correspondents sending wasps' nests should send also the queens belonging to them, so that they may be identified with certainty.

THE HISTORY OF THE STRAWBERRY.

IT was pointed out in a recent article on the genetics of the Strawberry (*Gardeners' Chronicle*, March 14, p. 186) that, although the origin of the present day fruit is complex and uncertain in detail, nevertheless we know and are able to discover more with respect to the evolution of this fruit than with respect to other cultivated food-plants. How much is and may be known is illustrated in an admirable article by Mr. E. A. Bunyard in the current number of the *Journal of the Royal Horticultural Society* (39, 3, April, p. 4). Our knowledge is due to the fact that the development of the Strawberry is comparatively recent, although, of course, *Fragaria vesca*, L. has been known and grown for many hundreds of years, and has been described or referred to by horticultural writers from the days of Pliny onward. From the casual comment of Shakespeare, "the Strawberry grows underneath the nettle, And wholesome berries thrive and ripen best Neighbour'd by fruit of baser quality," it may be inferred that so short a time as 300 years ago the Strawberry was not a fruit which raised the enthusiasm of the gourmet to the extent which it does at the present day.

A fact of cardinal importance is insisted upon by Mr. Bunyard—that *F. vesca* is no exception to the rule that wild plants vary greatly in their natural state. Of this Strawberry, a white form, a sterile form, and a large-fruited variety have been re-

corded in a wild state, and we may be sure that gardeners of the past were quick to avail themselves of the first and last of these variations.

Mr. Bunyard gives evidence in support of the view that the Strawberry was in cultivation in France in the fourteenth century, and we may take it that its present state is the result of some five or six centuries of selection and hybridisation.

In support of our suggestion that in its early days the Strawberry was not the delicious fruit that it is to-day, we may cite Mr. Bunyard's observation that Olivier de Serres, writing in 1600 (*Théâtre d'Agriculture*), values the Strawberry as much for its decorative use as for its fruit. De Serres recommends that plants should be taken from woods, and states that if transplanted to fresh soil their fruits increase in size, this improvement being ascribed to freedom from competition and to the effect of removal of runners.

Among the varieties of *F. vesca* which have appeared Mr. Bunyard mentions *F. aflagellis*, a runnerless form of compact habit; *F. monophylla*, first figured in a picture by Holbein and known to have arisen both among wild and cultivated Strawberries; the Alpine Strawberry, characterised by its habit of producing autumn fruits and first mentioned in 1530. Although the subject of controversy, it is probable that the Alpine Strawberry is not a garden sport but a true Alpine, and that it was introduced into gardens late in the eighteenth century. This form has thrown many varieties, the chief of which is the runnerless form known as "Gaillon." *Reine des Quatre Saisons*, a large-fruited form, was introduced in 1855.

The view has been expressed already in these pages that many wild plants suffer in their natural state from an inevitable repression, and that the larger growth which they make when brought into cultivation is due not to variation in a strict sense, but to a removal of natural disabilities. This view receives remarkable support from the results of experiments with Alpine Strawberries carried out by Henri de Vilmorin and cited by Mr. Bunyard; wild Alpine Strawberries growing in the neighbourhood of Barge-mont were planted by Vilmorin in his experimental garden and produced in the second year fruit equal in size to that yielded by the "improved varieties, such as Janus, Belle de Meaux, and Berger."

The other European species—*F. elatior*, the Hautbois Strawberry—was grown in gardens in the sixteenth century, and gave rise to varieties—Royal, Black, Prolific, etc.—which, whilst retaining the general characters of the species, were sufficiently distinct and toothsome to acquire a certain measure of popularity. The epoch-making period in the history of the Strawberry is, however, the early seventeenth century; for at that time the Virginian Strawberry *F. virginiana* was introduced—probably by Tradescant.

Although cultivated widely, more than 100 years elapsed before variations were recorded, and, indeed, *F. virginiana* had

to await the advent of the Chilian Strawberry *F. chiloensis* before its flavour, mated with the size of the latter, could yield fruits which are one of the chief material pleasures of early summer. It is fit that this *fraisier* should have been introduced by a French officer named Frezier, who found the Chilian Strawberry in both wild and cultivated state; it is also remarkable that, as Mr. Bunyard points out, one of Frezier's imported Strawberries planted near Brest was the origin of the large Strawberry-growing industry which is carried on in Brittany. All Frezier's plants were females, and it was not till Duchesne fertilised the Chilian with the Hautbois that fruit was obtained.

Mr. Bunyard has done a valuable service to the history of this fruit in settling the vexed questions of the origin of the Pine or American Strawberry, and tracing its parentage on one side to *F. chiloensis*.

The concluding part of Mr. Bunyard's study is devoted to the recent history of the development of the Strawberry and to a description of the parts played by Duchesne, Knight, Michael Keens, and Laxton, in hybridising descendants of the Virginian and Chilian Strawberry.

THE MARKET FRUIT GARDEN.

UP to April 11 inclusive my rainfall measurement was 1.02 in., and the only other fall to the end of the month was 0.01. The total for the month is not smaller than it has been in some previous seasons, but the practically uninterrupted drought of nineteen days, with blazing sunshine on all but two days, is unusual. Although the wind was from the north-east or east most of the time, it was seldom strong, and the sunshine kept the temperature high for April until the 30th, when there was a great fall. While Plums were in full blossom, there was no reason to complain of the weather, unless the continued dryness is to be regarded as adverse to the pollination of the blossoms. But the strong north-easter of the last day of the month, not tempered by sunshine, was a bad change for Apple and late Pear blossom. Almost invariably we have this bitterly cold wind when Apples are blossoming; but it may be hoped that the infliction will prove shorter than usual.

FRUIT BLOSSOMING.

The general promise of a full blossoming season for all kinds of fruit, referred to a month ago, has been amply realised. Even the Monarch Plum made a fair show on the whole, the scantiness mentioned last month having been found applicable only to some oldish trees, which in some former years had been badly injured by bud-eating birds. All the varieties of Pears grown by me were very full of blossom, and Cherries never made a better show. The same may be said of Gooseberries and Black Currants in my orchards. Red and White Currants are not remarkable. As to Apples, only some old and dwarfed trees of Lane's Prince Albert and Dumelow's Seedling, and some Gascogne's Scarlets, all of which were heavily cropped last season, have failed to show from fair to dense blossoms on trees old enough to render such displays desirable. The profusion of blossom on Beauty of Bath, Warner's King, Bismarck, Lord Derby, Golden Spire, Early Julian, Domino, Cox's Orange Pippin, and Allington Pippin is very striking; while Blenheim Pippin, Bramley's Seedling, Norfolk Beauty, James Grieve, and rather young specimens of Lane's Prince Albert

have quite full displays. Profuse blossom is not an advantage. It is a great tax on the vigour of the trees, and, when it sets freely, nothing but very severe thinning will secure fruit of full size or save the trees from serious exhaustion.

CHANCES OF POLLINATION.

So far as the fertilisation of blossoms of all kinds of fruit is concerned, there should be a good setting, for I have never seen bees working better day after day, so long as the sunny weather lasted. The number of bumble bees strikes me as quite extraordinary.

INSECT INFESTATION.

The greatest danger to the Apple crop at present observable in my orchards is the worst attack of Apple sucker that I have ever had. This was anticipated from the observation of swarms of the Psylla flying among the trees quite

sucker attack is worst on old trees, and is much more serious on some varieties than on others. Beauty of Bath, as usual, is one of the worst sufferers, Lord Derby, Lady Sudeley, Lord Grosvenor, and Lane's Prince Albert being, among others, severely attacked. As a rule, varieties with short-stalked blossoms are most infested, Lane's being an exception. These also are the most difficult to help materially by spraying, in consequence of the compactness of their bunches of blossom buds.

In addition to the insects named above, there are to be found in the trusses of Apple blossom here and there one or more of active little yellow bugs, with prominent black eyes. These Mr. F. V. Theobald, of Wye College, identifies as Capsidae, and describes as very harmful. The strong soft soap wash kills those which it wets thoroughly. These pests appear to have received attention in this country only recently.

in ten, at any rate before the blossom falls. This pest is sheltered to a great extent in the axils of the leaves and blossom buds, while the numerous globules of honeydew which it secretes shelter it further in many cases. It is of hardly any use to spray against the sucker until the blossom buds are well separated, which is not until they are on the point of expanding. Indeed, a few will be expanded by the time that nearly all will be sufficiently separated; but this does not matter much, if at all, when only a soft soap or nicotine wash is used. At the best, there will be a number of backward trusses of blossom buds which will be too compact for effective spraying. It is necessary to keep dodging about among the different varieties in order to catch each just when it is ready, and, unless the grower has a very strong staff of sprayers, he may be unable to get all sorts done before some are in blossom. My trees are sprayed with a strong soft soap wash which will kill any sucker, aphid, or half-grown caterpillar which its wets well, and the trees are drenched. Yet, on examination two days after the operation, I find at least half a dozen live pests to one dead enemy. When the blossom has fallen the operation will need repetition on some varieties. Then there will be a better chance of reaching the suckers. At first they are difficult to find, though their globules of honeydew indicate their presence quickly. The strength of the wash used is 12 lb. of soft soap to 100 gallons of water, which is about double the strength commonly recommended. Formerly Quassia was used with less soap, but has been discarded because on trial alone of eight times the strength recommended for Quassia extract, it entirely failed to kill aphid. For generations Quassia has been commonly used, probably without any result, the money spent on it being wasted. As to nicotine, apart from its prohibitory price, my experience is that, in ordinary strength, it does not kill aphid as well as soft soap does.

SOFT SOAP AND ARSENATE OF LEAD.

As the strong soft soap wash kills young caterpillars well wetted by it, there is no need to add arsenate of lead until after the blossom has fallen, when it is needed to poison the food of the codling moth and leaf-eating caterpillars, the latter by that time approaching their full size. In one list of spray stuffs it is stated that arsenate of lead should not be mixed with soft soap or any other alkaline substance. This implies that two sprayings must be applied instead of one when either caterpillars and sucking insects or either with scab require treatment. But I have used arsenate of lead mixed with soft soap or with lime-sulphur for years with impunity, except on one occasion, when a particular brand of soft soap was used, and then scorching of foliage and defoliation resulted. On that occasion, too, the arsenate of lead and soft soap were mixed in their concentrated forms, whereas it is safer to add the former to the diluted soft soap wash. It is a serious matter to have to spray extensive orchards twice instead of once after the fall of the blossom. Probably the soft soap which did harm when mixed with arsenate of lead contained an excess of caustic potash, which liberated arsenic. The best soft soap should be used.

A DANGEROUS REPORT.

A report from California to the effect that spraying Apple trees in blossom with nitrate of soda at the rate of 1 lb. to one gallon of water has produced marvellous increases in crops of fruit, is calculated to do much harm. It seemed incredible that so strong a solution could be safely used on foliage or blossom buds, and a trial on a small scale proved that it killed in twenty-four hours or less every leaf or truss of blossom buds which it wetted. A correction has since appeared stating that the spraying should be done to dormant trees only. *Southern Grower.*

FIG. 136.—ODONTOGLOSSUM LAKINAE: PETALS AND SEPALS BLOTCHED WITH CLARET COLOUR TINGED WITH VIOLET.

(See p. 311.)

into the winter. On the other hand, with me there is the most remarkable immunity from aphid attack that I have ever enjoyed. Hardly any aphides have been found on Plums, and out of more than a thousand trusses of Apple blossom examined with a lens, only eight contained an aphid. Even Roses are almost entirely free at present. This immunity, which does not appear to be at all common, as there are many reports of aphid on both Plums and Apples, is a complete mystery. It cannot be accounted for by spraying, as it applies equally where trees were sprayed with lime or lime-sulphur, shortly before the buds burst, and the latter wash has been used year after year without preventing the great aphid infestations which have been usual in my orchards. Moreover, the lime was nearly all washed off the trees two or three days after its application; and, again, separate trees purposely left unsprayed are as free from the pest as those which were limewashed. Fewer thrips than usual, and, I think, fewer caterpillars, have been found in the blossom trusses of Apples. The

THE FORLORN HOPE OF SPRAYING.

We fruit-growers keep on spending large amounts of money in spraying without any reasonable hope of more than partial benefit. It is doubtful whether any winter wash destroys the eggs of any insect. A caustic wash, such as caustic soda, will go far towards the destruction of colonies of the woolly aphid, commonly called "American blight," and other washes will kill the scale insect. For such purposes, as well as for keeping trees clear of moss and lichen, winter spraying is well worth while. But it has never been actually proved that any winter wash destroys the vitality of aphid or sucker eggs, or keeps them from hatching. That spraying Plums or Apples against the leaf-curling aphid after an attack has caused the curling is a waste of time and money is so obvious to me that I have given it up entirely. The case of the apple-sucker is different, as it is not viviparous, as the aphid is; but it is doubtful whether a single spraying, however well done, kills more than one sucker

ORCHID NOTES AND CLEANINGS.

ODONTOGLOSSUM LAKINAE.

In the *Gardeners' Chronicle* for November 8, 1913, p. 317, this beautiful hybrid Orchid was described as "one of the largest, best shaped, and richest in colour of any known *Odontoglossum*." The plant was exhibited by Messrs. E. H. Davidson and Co. at the meeting of the Orchid Committee on April 7 last, when the photograph reproduced in fig. 136 was taken.

The ground colour is white, shaded by the deep violet tint on the backs of the segments, the blotching claret-coloured, with a tinge of violet. It was named in compliment to Mrs. Lakin, the wife of Mr. J. B. Lakin, managing director of the firm of Messrs. E. H. Davidson. This fine *Odontoglossum* is another addition to the ranks of those classed as "parentage unknown." Where any doubt exists (and we fear there are doubts in many cases in which attempts are now made to give the parentage) it is much more satisfactory to leave the question open, for after all the merit of the flower is the matter of chief importance to the gardener. Nevertheless, we counsel all raisers to take every possible means of accurately recording the parentages of their hybrids as a means of rendering possible the elucidation of the scientific points in the complex problems of hybridisation.

MESSRS. WILLIAM BULL AND SONS' EXHIBITION.

THE annual spring exhibition of Messrs. W. Bull and Sons was first held in 1831. The show was formerly devoted entirely to the display of Orchids and new plants, but in more recent years the decorative plants of the season have been used as a setting, and the *Hippeastrums*, for which the establishment is noted, have increased in number until at the present time the show is largely composed of those plants. At this year's show, which opened on the 7th inst., about 600 specimens in full bloom were arranged along the paths beneath the stately Palms and Tree Ferns. The plants are usually massed in groups of one colour, a method which renders them more effective than when they are mixed indiscriminately. At the same time it shows the constancy of some of the new tints of plum colour, mauve, and salmon-red, several of each being arranged together. The space at the Chelsea Winter Gardens has been enlarged this season by including the walks on the office side of the central path. Here the most distinct *Hippeastrums* are Blush Rose, a white variety with rose flush; The Bride, white; Kathleen, large and of fine shape; and Clarice, white, prettily marked with mauve; Winifred is a light plum colour; Queen Mary, pure white; Princess has a white centre, and the petals are tinted rosy-mauve; Queen Alexandra is white, the outer parts being flaked with salmon-scarlet. King George V. is the best dark red; it has two spikes each of four immense flowers of fine shape. A group of light shades is distinguished by The Pearl, Rosamond, and Bridesmaid; the quality is excellent throughout, and the group is all the more interesting in that the plants are raised, grown and flowered in London.

The Orchid section of the show is varied by the addition of Roses, Lilies, and other flowers. The *Cattleya Mossiae* and other large-flowered *Cattleyas* were well represented, and a number of specimens of *Laelio-Cattleya* General Baden Powell were also shown. A selection of seedling *Odontoglossums* raised at Chelsea contained some good blotched forms of *O. crispum*. Prince of Wales is heavily blotched with dark claret colour, the lip also being much marked. Several others were very promising, the blotching varying in tint, but the flowers always of good form. *Cattleya Thayeriana alba* (*Schröderae alba* × *intermedia alba*) is a good white flower. *C. Mendelii* Countess is also a good white, with deep mauve lip. A number of specimens of

Brasso-Laelia, Helen showed great variation in tint. Specimens of *Dendrobium nobile*, *D. thyrsoiflorum*, other *Dendrobiums*, and various *Cypripediums* were well displayed.

FLORESTERS' FLOWERS.

DAHLIAS FOR HOUSE AND TABLE DECORATION.

THE oft-repeated question addressed to me at Duffryn when showing the Dahlia trials to visitors, "Which are the best for cutting?" has prompted me to write a short article dealing exclusively with this aspect of our favourite flower. Taking them collectively, it cannot be claimed that Dahlias have the lasting qualities of many other flowers that could be named, but the remark often heard, "What a pity they won't last in water," is really an indication of imperfect knowledge. There are plenty which last for more than a week with ordinary care, and we have found some Stars and Collettertes to last over a fortnight.

A letter received recently from South Africa, asking for information, said: "My varieties

prettily edged, like a Picotee, with another colour. All are good, but preference may be given to Jupiter, white, with yellow edgings; Mercury, white, edged scarlet; Cetus, white, edged rosy-violet; Orion, white, edged yellow and crimson; Aries, white, edged crimson-scarlet. Some of the varieties are given to sporting, usually throwing a self-coloured bloom of the same colour as edging.

Most of the Collettertes are excellent for cutting. It is passing strange that they should last so much better than the singles. I have wondered if it is the Colletterte itself which holds the florets together. The singles appear to drop immediately the stamens are fully developed. Here it may be mentioned that when cutting care should be taken to choose blooms which are just opened and the pollen is beginning to be shed. Some of the large-flowering types of Collettertes are grand, notably *Diomède* and *Souv. de Chabanne*. Both have very long stalks. The blooms of the former are rough, but the rich rosy-crimson and white flowers are very effective for house decoration. A bunch of this particular variety was gathered the day before a frost laid them all low. Extra care was therefore taken

FIG. 137.—VIEW IN THE CONSERVATORY AT MESSRS. W. BULL AND SONS' NURSERY.

have such weak and frail stems, and are practically useless for cutting." Quite so; hence the necessity of growing only those having long and rigid flower-stalks, with the blooms standing bolt upright. Such varieties are to be had in most of the sections.

It is surprising what a difference there is in the lasting qualities of cut flowers of the various types. Taking the sections in their order of merit for our purpose, I place them: Stars 1st, Collettertes 2nd, Paeony-flowered 3rd, Decorative 4th, with the Cactus, Pompon and singles following.

Owing, possibly, to their being overshadowed by the brilliance of other types, the dainty Stars are not much known. They should appeal strongly to everyone on the look-out for cutting varieties; for they have far and away the stiffest and most erect flower-stalks of any type. The flowers are single, with gracefully curled and pointed florets, which give them a lightness so much desired for table decoration. There are only eight or nine varieties, each named after a star. The blooms are of white or creamy-white ground, each petal being

to prolong their life, and the last faded bloom recorded the fact that for three weeks it had stood the test of time. Others to be specially recommended are *Diadem*, rich rose colour; *Goldstern*, for those who are partial to lemon-yellow; *The Needles*, rose and white; and *Queen Mary*, rose. These are suitable for table-work. The art shades of *Windsor* and the bluish-violet of *Madame Poirier* appeal to many.

The Paeony-flowered and decorative types give us the best flowers for large vases. Of the Paeony-flowered, *Hampton Court*, *Mrs. Kerr*, *Sheila*, *Hermosa*, *Salome*, *H. I. Lovink*, *Snow-cloud* and *Andrew Carnegie* are the pick of the soft shades. *Liberty*, *John Green*, *The Warrior*, *Bayard*, *Vulcan* and *Unique* supply the bright and dark colours. A few giant decorative for a very bold arrangement are *Mammoth*, *Souv. de Gustave Douzon* and *The Giant*, all bright. Of medium size, *Délice* and *Loveliness*, pink—are favourites with all. So, too, is *Harmony*, a lovely sheeny-pink. *Princess Juliana* is a grand white, with stalks 18 inches to 2 feet long, and *Lagdene*, rose and white, makes a delightful vase. To this list I would

also add the daintily coloured little Sea Shell and Orange Glare of the Garden. The latter, perfect in its habit, gives a good object-lesson as to how a vase of flowers should be arranged.

How disappointing it is that one cannot write in praise of the beautiful Cactus flowers. They are very erratic, some of the most desirable varieties, such as Sweet Briar, fading almost immediately when cut. A few varieties found to last fairly well are Conqueror, Jenny Wren, White Ensign, Carrie Hammond, Miss Willmott and Salmon Queen. On the whole, the naturally small bloomers are the most satisfactory and make very pretty vases and bowls. Nimrod, Mrs. John Barker, Pink Perfection, Bridal Crown, Rev. M. Limon and Pink Pearl are a few of the best.

The charming singles, which I am sorry to have to place in such a lowly position, are unaccountably poor lasters. If, as previously mentioned, great care is exercised when gathering one may hope to keep them three or four days. They are, however, very useful for table decoration where changes are introduced frequently. Many pretty colour schemes can easily be effected, as they possess such a range of colour. Rosemary Bridge, Lady Bountiful, Rosy Gem, Mary, Ouida, Donna Casilda, Mrs. T. W. Bates and William Parrot can be confidently recommended.

I have seen it stated that the Pompons are good lasters, but my experience does not go to prove this. In any case, there are many types to be preferred, and we can afford to leave the Pompons to the place to which they seem best suited—namely, the garden. *Arthur J. Cobb, Duffryn Gardens, Cardiff.*

ANNUALS.—V.

THE CANDYTUFTS.

CANDYTUFT has, more than any other annual I know, been the means of "depressing" annual culture. A penny packet purchased and sown in the usual way in a border and left unthinned produces a common, fleeting and most unsatisfactory result. One-tenth of the quantity of seed sown on the same area, and the plants thinned if necessary to 4 or 6 inches apart, gives a beautiful and lasting effect, as the plants develop side branches which bloom well.

Candytuft (*Iberis umbellata*) has long been grown in English gardens. It is referred to by Gerard. Then there is the Rocket Candytuft (*Iberis coronaria*), from which the giant spiral forms have come. It was a much later introduction, Nicholson giving the date as 1836. Recently there has been a new race of hybrids introduced. Originating in France, it has been worked by the leading English growers, several of whom have very fine strains. The Rocket Candytuft gave rise to the giant spiral or Snowflake variety, about 1879, and, like the waved Sweet Pea, this giant form appeared in a number of different places about the same time. It is the finest form of Candytuft, but it is difficult—impossible, I might say—to get it to breed true, the very best strains giving a proportion of small-flowered forms with small spikes. When thinning care should be taken to leave seedlings with broad leaves, as they generally produce the desired big spikes of bloom. Candytuft is chary of transplantation, but the plan which I recommended for Mignonette may be adopted with success.

C. Giant spiral.—Giant Snowflake, Hyacinth-flowered, and other names are given to this grand form. It grows from 12 to 15 inches in height, and the term Hyacinth-flowered best describes the flower-spikes, which are often 9 inches long by 2 to 3 inches in diameter. It is singular that up to the present this form has not appeared in any other colour.

C. crimson.—Dunnett's is the best known. It gives very rich purplish-crimson flowers. The flower-heads are $1\frac{1}{2}$ inches wide by about an inch deep.

C. carmine grows quite a uniform height of 12 inches, and has carmine petals. In a dry season like 1913 it might well be termed a bluish carmine.

C. lilac.—In habit exactly resembles the foregoing, but produces in great profusion large heads of beautiful, warm-toned lilac flowers.

C. Rose Cardinal.—This was introduced a few years ago and is a most distinct and beautiful variety. The flowers are of good size and of a rich rose-colour.

C. atropurpurea.—Similar to Dunnett's crimson, but a shade darker in colour and rather taller in growth.

C. dwarf Hybrids.—Growing about 9 inches in height, these are most useful for bedding, and can be had in different shades, such as rose, crimson, lavender and white.

C. sweet scented.—This, in the early stage, is not at all like a Candytuft, having distinct soft-green deeply serrated leaves. When in blossom it resembles the perennial form *sempervirens*. It is strongly scented.

C. Little Prince.—This fine dwarf form has already been referred to. It grows from 6 to 9 inches in height, according to soil and locality.

FIG. 138.—CANDYTUFT LITTLE PRINCE: FLOWERS WHITE.

and produces fine large flower-heads (see fig. 138). *W. Cuthbertson.*

A BORDER OF ANNUALS.

The illustration (fig. 139) shows a fine border of annuals in the kitchen garden at Ballyfin House, Queen's County, Ireland. Mr. H. Thornton, who sends the photograph, informs us that the garden, which is walled, covers an area of five acres, and the border runs through the centre. In the season it makes a charming picture, and is planted each year with a choice variety of the best annuals, nearly all of which have been previously raised under glass, to prolong the flowering season. It is in June, July, and August that the colouring is at its best. Alyssum Little Gem is employed as a groundwork. The borders on each side are 156 yards long and 10 feet wide. Along the back of each border is a pergola made of Holly-wood. It is being furnished with rambling Roses. About half-way along the border is an octagon summerhouse, over which climb Roses, Ampelopsis, Wistaria and Clematis.

NOTICES OF BOOKS.

HISTORY OF THE CARNATION.*

This book contains 212 pages of literary matter, printed in a clear, readable roman type, and deals with the history, literature, and artistic features of the Carnation in a manner never yet attempted by any horticultural writer. There are 53 illustrations in black and white, besides two in colour.

In his researches in mediaeval literature Dr. Kronfeld has had access to works but little known to English writers, and some of his reproductions are not only quaint but highly instructive to the student of floricultural history. The work is written in German, and practically the whole of the illustrations are reproduced from German sources.

Our readers are well aware of the antiquity of the Carnation as a popular flower, not only here, but in France and Germany. It was grown and appreciated centuries ago, and its literature is as important as that of the Tulip, the Auricula, the Hyacinth, and other old flowers.

One of the earliest pictures given by the author is fig. 3, in which a young couple are seated on a bench beside a pot of Carnations in flower. It is reproduced from an engraving by J. van Meckenen, of Bocholt (1482-1503). Another, from *Lustgarten und Pflanzungen*, Strasburg, 1530, shows a gardener at work; in the background are three Carnation plants in pots on a stage. Fig. 5 shows a pot of Carnations in bloom, after Bock, 1546. The plants, instead of being staked, are supported by a curious light framework of circular form that keeps them in position and the blooms from drooping. Another illustration shows a Carnation in two-handed vase, after Castore Durante, 1636.

Dr. Kronfeld has also illustrated his work with a series of reproductions of old pictures by famous painters, in which Carnations are more or less prominent. These have been collected from art galleries in Frankfort-on-Main, Vienna, Berlin, Cologne, Munich, and other places. We note particularly the portrait of Simon George holding a Carnation, a work painted by Hans Holbein the younger. The same artist is represented in his portrait of the Merchant Gisze, on whose table is a vase containing cut Carnations. A full-faced, half-length portrait of a young man by Heinrich Aldegrever is another instance of the subject with a Carnation in his hand. Similar to these are fig. 15, Lucas Van Leyden's portrait of the Emperor Maximilian I., and fig. 16 Chris. Amberger's portrait of Ulrich Sulzer. Fig. 18 is Jan Van Eyck's picture, entitled "The Man with the Carnation." Fig. 20 Rembrandt's "Saskia with the Carnation." Fig. 23 is Leonardo da Vinci's "Madonna with the Carnation," and so we might continue with these interesting old pictures.

The book is divided into nine main chapters, which in turn are sub-divided into minor headings. The whole field of Carnation lore from the history of its earliest forms down to present-day culture is covered, be it in England, France, Germany, or America. The references to authors, poets, and other writers are numerous, and include citations from James Douglas, Parlatore, Ponsort, Vallet, Buc'hoz, Ardene, Weissmantel, Freund, Wallace, Grotjan, Hertel, and many others.

The extracts from the old writers on the Carnation show how thoroughly the author has traversed the ground. A noticeable feature of the book is the numerous poetical, mostly German, allusions culled from many sources. We may conclude by saying that those of our readers who are lovers of the Carnation, and who can

* *Geschichte der Gartennelke.* By Dr. E. M. Kronfeld. (Vienna, Verlag der K.K. Gartenbau-Gesellschaft, 1, Kaiser Wilhelmring.) 12s.

follow the author in his own language, will obtain much satisfaction from a perusal of a work which will certainly take high rank among books devoted to floricultural history. *C. H. P.*

PLANT NOTES.

TUBEROUS BEGONIAS FOR HANGING BASKETS.

In the case of Begonias for pot culture a sturdy, compact habit is an important consideration; but for hanging baskets, the reverse holds good. Varieties of a loose, more or less pendulous style of growth are seen to very great advantage when suspended. Of late years increased attention has been bestowed upon Begonias for this purpose, with the result that several varieties have recently been brought forward particularly adapted for growing in

of limestone rubble without affording the roots any water all the year round, except when the flower buds appear in midsummer, and then very little, taking care not to wet the rest of the plant. During the remainder of the year I keep the roots cool by placing the pot in a larger one, and filling up the space with Sphagnum-moss, which is wetted once a week in summer. In a continued frost the plant is liable to be injured, but if the temperature is not allowed to fall below 45° F. and the plant kept dry, it does not appear to suffer. This method of keeping roots cool is applicable to many plants in pots which need to be exposed to the sun's rays, since plants usually choose the moist but well-drained sides of the pot to form a profusion of roots. An extract from the plant is used in Mexico to produce a kind of intoxication. It is there known as "Pellote," and has been introduced into medicine in the United States under the name of "Mescale buttons." It produces curious

moraine containing no lime, facing almost due east, without any glass protection. It was quite good last summer when in bloom, and was left unprotected by glass with a view of testing it. *H. frigidum* does not suffer from frost so much as from wet in winter. It is a very dainty Alpine with small, silvery foliage and delightful little white flowers produced in summer and autumn. *S. Arnott, Maxwelltown, Dumfries.*

SCOTLAND.

NEW PARK FOR GLASGOW.—Lord Glenconner has intimated to the Lord Provost of Glasgow his desire to present the city of Glasgow with a park of 13 acres in the St. Rollox district, with which he and his family have long had a special connection. Lord Glenconner has also offered

FIG. 139.—BORDERS OF ANNUALS AT BALLYFIN HOUSE, MOUNTRATH, IRELAND.

[Photograph by J. P. Greene.]

baskets. The main characteristics of these are a drooping habit of growth and a profusion of showy blossoms. Among the most suitable for the purpose are *Alba Plena Fimbriata*, white; *Alice Manning*, yellow; *Carmina*, carmine-red; *Ennice*, pink; *Fleur de Chrysanthème*, salmon-pink; *Gladys*, dark red; *Golden Shower*, much the colour of *Rose William Allen Richardson*; *Lena*, rosy-crimson; and *Mrs. Bilkey*, orange-salmon. A particularly vigorous kind is *Mario Bouchet*, but it is only fitted for cultivation in large structures. When these Begonias are intended for growing in baskets, it is a good plan to start the tubers in small pots, planting them into the baskets when they have made a few inches of growth. It is essential that this be done before the plants are pot-bound, otherwise they will receive a decided check. *W. T.*

MAMMILLARIA (ANHALONIUM) WILLIAMSII.

I HAVE grown and flowered this remarkable cactaceous plant for several years in a pot

physiological disturbances, one of the most remarkable affecting the vision, and causing the illusion of a kaleidoscopic play of colours. *E. M. Holmes.*

THE ROCK GARDEN.

CORIARIA TERMINALIS.

THERE are two things which militate against the value of the pretty, small shrub *Coriaria terminalis*, the graceful habit of which makes it so suitable for rock gardens or sunny banks. First, that in some northern gardens it does not flower; and second, that if it does, the birds eat the fruits almost immediately. The habit, however, is graceful and arching, and the autumn colouring of the leaves is attractive.

HELICHRYSUM FRIGIDUM.

HELICHRYSUM FRIGIDUM has stood the past winter, which was an unusually wet one, on a

the sum of £1,000 to assist in the laying out of the ground.

EDINBURGH PUBLIC PARKS.—The estimated sum to be expended on the Edinburgh parks and gardens for the year 1914-15 amounts to £16,455, as compared with an estimate for 1913-14 of £15,955, and an actual sum of £16,380 expended in the year 1912-13.

FOREST FIRES.—The dry weather has been responsible for a number of forest fires in Scotland. In Inverness-shire thousands of trees were burned at Balblair, on the Seafield and Raigmore and other estates. A considerable amount of damage has been done to trees and moorland in other parts of Scotland.

EDINBURGH SHOW.—The attendance at the spring show of the Royal Caledonian Horticultural Society on April 29 and 30 showed a considerable improvement over last year. The receipts were about £17 more than at the show of 1913. (See p. 323.)

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON, Oakwood, Wylam-on-Tyne.

LAELIA.—The small-growing *L. pumila*, also *L. praestans* and *L. Dayana*, are making fresh growth, and may be re-potted or top-dressed, as is considered necessary. They grow best in shallow pans or baskets, just sufficiently large to contain the roots. These miniature-growing plants are serviceable for autumn flowering.

ODONTOGLOSSUM HARRYANUM.—The plants are developing fresh roots from the bases of the growing shoots, and may be re-potted or otherwise attended to at the roots, for the sooner the plants are re-potted after new roots make their appearance the better, as the latter are very liable to be injured. This Orchid is not always grown satisfactorily in gardens, but it is surprising what rapid progress the plants make when suitable conditions are afforded. It is not advisable to use larger pots than will accommodate the roots. The plants grow best in well-drained pots: a few pieces of broken crocks should be placed over the drainage hole, about two-thirds the depth of the pot being filled with chopped Bracken rhizomes. If the old compost is in a state of decomposition, the whole should be carefully removed and the plants re-potted in fresh material consisting of good fibrous peat and *Osmunda*-fibre in equal portions, with a few broken leaves and chopped *Sphagnum*-moss intermixed. Sufficient broken crocks and sand should be added to render the compost porous. Press the materials firmly about the roots, and after re-potting carefully shade the plants for a few weeks. Keep the atmosphere humid, damp the surroundings, and spray the plants overhead in favourable weather. Hybrids of *O. Harryanum* are far more amenable to cultivation than is the species, for they are, without exception, exceedingly vigorous growers. Many *Odontoglossums* have been intercrossed with *O. Harryanum*, so that there are numerous secondary and bigeneric hybrids. Among the latter the vigorous *Odontioda Charlesworthii* (*Cochlioda Noezleana* × *O. Harryanum*) is one of the most serviceable, the long spikes of brilliant scarlet flowers being very effective and useful for any purpose where bright colour is desired. The plants may be grown under the same conditions as *Odontoglossums*, but their re-potting should be attended to at the time the new growths appear.

THE FLOWER GARDEN.

By W. CAUMPT, Gardener to Earl BEAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

SPRING FLOWERS.—There is an abundance of choice and specially interesting bulbous flowers just now, and fresh subjects are opening day by day. At Madresfield Court most of the plants are growing in specially prepared stations, and in shade or shelter, in accordance with individual requirements. How lovely are all members of the *Erythronium* family [Dog's Tooth Violets], including *Pink Beauty*, *Gigantea robusta*, *White Beauty* and *Hartwegii*! *E. Dens-canis* will do well in turf if the grass is not too rank. Then, again, what can compare with a large colony of either *Anemone Robinsoniana*, *A. blanda*, *A. fulgens* King of Scarlets, *A. apennina coerulea*, or *A. pulsatilla*, all of which are easy to grow? We plant them on a gentle slope in prepared ground, with a few stones irregularly let in the ground, to guard them when dormant. They should be sheltered from blazing sunshine and frosty winds by a neighbouring shrub, but they must not be subjected to the drip of overhanging forest or evergreen trees. The *Polyanthus* is now at its full beauty, in company with *Aubrietias*, *Primula nivalis*, *P. denticulata*, *P. cashmeriana*, *Alyssum saxatile*, *Trilliums*, *Tritielias*, *Arabis*, *Wilson's Blue Primroses* and *Auriculas*. The notebook will be in use daily with a view to recording errors or successes, either in the arrangement of the colours, heights and habits of the

various plants, their approximate dates of flowering, and suggestions for improvements; such notes will be found most valuable when planting time comes round again. It has been said that greater profit results from errors or failures than from successes, for the former develops energy and perseverance, whilst the latter may beget conceit and laxity.

VASES FOR SUMMER EFFECT.—The vases on terraces, etc., should be prepared for planting. Make provision for drainage and fill them with rich, turfy loam and decayed leaf-mould in equal parts, adding a dash of grit, sand, or old lime rubble to make the soil porous. For continuous summer blooming I know of nothing to equal Ivy-leaved *Pelargoniums* of such varieties as *Madame Crousse* (pink and double scarlet), *Souvenir de Ch. Turner*, *Galilee*, *Baden Powell* and *Mirillo*. The double *Marguerite Mrs. F. Sander* is a good white flower for this purpose.

TREE PAEONIES.—The newer forms of these gorgeous-flowering shrubs, and especially those of the Japanese section, should have their flower-stems supported by stout stakes, which should be hidden by the foliage. Remove any suckers that appear. It is a pity that a more natural and longer-lived stock is not employed for grafting, seeing that our plants are constantly dying in spite of every possible attention. Many of the fleshy roots grow near to the surface, and a mulching of horse-droppings is beneficial; or the roots may be fed with a little fertiliser. The single-flowered herbaceous *Paeonies* are almost in flower; these may be cultivated for years with but very little trouble.

THE IRIS GARDEN.—A good dressing of soot applied from time to time will give colour to the flowers and foliage of the beautiful *Iris germanica* varieties, for soot is always a safe and trusty stimulant. The plants resent disturbance at the roots, therefore transplanting should always be deferred until the clumps are crowded. It is better to remove surplus growths as soon as the flowers are over and to transplant the portions in the reserve garden. A selection of varieties includes *Jaquesiana*, *Mme. Chereau*, *Bridesmaid*, *Mrs. Darwin*, *Purple King* and *Black Prince*. *Iris Kaempferi* flowers later, and succeeds best in partial shade, planted along the margins of lakes or streams, in company with such tall varieties as *I. Monnierii*, *I. ochroleuca* and *I. gigantea*.

MULCHING.—This is an important matter as regards all newly-planted subjects, for it is far better thus to conserve natural moisture in the soil than to have to resort to artificial watering, besides the economy of labour—no small desideratum nowadays.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

HIPPEASTRUM.—The plants have almost finished flowering, and should be placed in a warm pit to complete their growth. Plunge the pots to their rims in a mild hotbed, tie the leaves to a stake, and encourage the growth of bulbs and leaves as much as possible. If a special house is not available for the plants they may be grown in a Peach or other suitable house. Feed the roots once a week with liquid manure and use the syringe freely. If the sun is very powerful shade the plants lightly for an hour or two about midday for the next month, but after that time full exposure to the light will be beneficial. For accommodating seedlings prepare a bed inside a frame, and after allowing time for the fermenting materials to subside place a layer of fairly rich, light soil to the depth of 9 inches, and plant out the young bulbs at 9 inches apart in lines made 1 foot apart. Syringe and close the frame early each day. If the plants are kept growing in a healthy condition a fair percentage may be expected to flower during their third year. Maintain a night temperature of 60° to 65°.

TREE CARNATIONS.—Plants raised from cuttings in autumn are making fresh growth after having been stopped for a second time. Our

plants are being shifted into 7-inch pots, in which they will flower. Suitable soil for this potting is composed of three parts yellow loam and one part each of mortar, rubble and wood ash, the whole enriched with fertiliser at the rate of a 6-inch potful to each barrow-load of compost. If the loam is very stiff and retentive, add a little coarse grit or broken oyster-shell. Pot firmly, and when the work is finished stand the plants in a cold pit or frame on an ash bottom, taking the precaution to first dust the floor with soot. On bright days spray the plants very lightly and damp between the pots, but moisture must be afforded the roots with discretion until the plants become re-established. Plants propagated from cuttings this spring are making headway, and ready for transference to receptacles 4½ inches in diameter. Admit full ventilation on fine days, allowing the roof apertures to remain open all night in favourable weather. Stop the shoots of plants rooted later when about eight pairs of leaves have developed, and re-pot the plants into large 60-sized pots when the secondary growths are 2 inches long. Flowering plants are growing strongly and need feeding occasionally with a concentrated fertiliser. If they are required to flower in the second year they may be re-potted at the end of the present month, or early in June. If the blooms become bleached by the sun, shade the roof-glass lightly during the hottest part of the day. *Souvenir de la Malmaison Carnations* are sending up their flower spikes, and need close attention in the matters of tying the stems and watering the roots. *Aphis* sometimes infests the flower spikes, and should be destroyed by light fumigations. If the sun is very strong a light shading will be beneficial for a few hours during the hottest part of the day. Damp the paths and stagings and ventilate the house freely.

MISCELLANEOUS WORK.—Pot seedlings of *Celosias*, *Balsams*, *Lobelia tenuior*, and *Statice Suworowii* in small pots filled with light, porous soil. Stage the plants close to the roof-glass, and syringe them freely overhead. Fumigate the house at intervals. *Achimenes* and *Gloxinias* are filling their pots with roots, and may be watered with weak liquid stimulants. Annuals such as *Mignonette*, *Gypsophila elegans*, *Calliopsis*, and annual *Chrysanthemums* in pots should be thinned severely and grown in a cool frame. Insert cuttings of *Coleus thyrsoideus*, *Centropogons*, *Eranthemums*, *Euphorbias*, *Justicias*, and fibrous-rooted *Begonias*.

FRUITS UNDER GLASS.

By W. HEOLY WARREN, Gardener to the Astor-Clinton Park Estate (the Rt. Hon. LORD ROTHCHILD), Buckinghamshire.

PINES.—The size to which the fruits will ultimately grow depends mainly upon the condition of the roots, although general good management will conduce much towards the health of the plants. A sure criterion of the state of the roots is the quantity of water they absorb, for, as a general rule, those that require a copious supply of moisture develop the finest fruits. The plants should be grown in the same temperature as hitherto and be treated as previously recommended for both the fruiting specimens and successional plants. The smallest of the suckers potted last March are ready for re-potting, and the work should be done at once. If the bed in which the plants are plunged requires refreshing, now is the time to do it by adding a little fresh fermenting material to the surface and turning the whole over to a depth of about 15 inches, to incorporate the new with the old. After the plants are again plunged watch the temperature of the bed carefully to see that fermentation does not cause it to rise too high.

PEACHES AND NECTARINES.—The fruit in the earliest houses—and especially on pot trees—is nearing the ripening stage. Continue to afford the roots copious supplies of water, but reduce the amount of syringing overhead according to the stage of the fruit's ripening. Maintain plenty of atmospheric moisture and permit a free circulation of air, both by day and night. These details are essential to the health of the

trees, which otherwise would be most injuriously affected should the wood be prematurely ripened. Continue to regulate and tie in the shoots of trees in successional houses, retaining only sufficient new growth for fruiting next season. All shoots above or beyond the fruit should be stopped closely with the exception of the leading branches, and the fruit should be exposed as much as possible to the sun. Ventilation must be sufficient to ensure short-jointed and firm growth, and when necessary all inside borders should be watered thoroughly. Feed heavily-cropped and weakly trees by top-dressings of rich materials, liquid manure, or concentrated fertilisers, washing the last into the borders with clear water.

CUCUMBERS.—The plants are growing freely; plenty of moisture should be afforded the roots and the atmosphere kept moist by damping the paths and staging several times a day. As the fruits develop afford top-dressings of good rich loam and decayed manure to encourage the development of roots on the surface. When the plants have furnished the space keep the shoots thinned to prevent overcrowding, but before doing this remove all rusty-looking leaves except those on the same joint as the fruit. Green fly and thrips may be troublesome at this stage and must be destroyed by fumigating the house with a nicotine preparation, which is safer to use than insecticides in solution.

STRAWBERRIES.—During times of bright sunshine accompanied by drying winds insect pests, and especially red spider, spread rapidly on the mature foliage of pot Strawberries grown under glass. For this reason Strawberries in Peach and other fruit houses may be a source of danger to the fruit trees, and it will be advisable to remove infested plants to other quarters to ripen the berries. Should the fruit on successional plants be ripening too fast they may be retarded by turning the fruit from the sun or by removing the plants to cooler quarters. Plants that are still plunged in beds out-of-doors should be placed in cool frames. Syringe them daily until the flowers begin to open, and use diluted manure water at every alternate watering. Reduce the flower-spikes to the requisite number, and if the pots are stood on ashes, or half-plunged in the same material, it will be an easy matter to maintain a moist, genial atmosphere favourable to healthy growth. Allow sufficient space between the glass and the plants to permit of a free circulation of air, as the foliage is easily scorched. Excellent fruit may be grown in frames and the berries will maintain an unbroken supply until the out-door crop is ready.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOLE,
Eastwell Park, Kent.

PEACHES AND NECTARINES.—April generally was bright and sunny with mild nights the weather being very favourable for the blossoming of Peaches and Nectarines. Bees have been busy amongst the trees, and there is every prospect of good crops in this locality. The genial weather has also been favourable to growth, which is unusually forward, and the work of disbudding the shoots should be commenced at once. Healthy, vigorous trees of these fruits always produce a large number of shoots, and unless severe disbudding is practised the trees become laden with growth that does not ripen properly because of overcrowding. In commencing the work first remove all foreright shoots, and such as develop at the back of the tree facing the wall. When these are all removed, commence the work of disbudding proper at the top of the tree. The degree to which this is done will depend upon the age of the tree, that is, whether it is an established specimen filling the whole of the wall space or a young plant that is required to extend. It is a common error to permit too many shoots to remain, as the surplus ones have to be removed later on after they have taken much of the energy of the trees. A well-placed shoot at the base of a fruiting branch should always be retained, with a view to training it in the place of the latter after it has fruited. The aim of the cultivator should be to retain sufficient young

shoots to furnish the tree after the old fruit-bearing wood has been cut out in the autumn. Train in the young shoots in such a manner that they will not shade the fruits, which is one of the chief reasons for keeping the trees trained as thinly as is consistent with their carrying a full crop. If the weather turns dull and cold, defer the work of disbudding for a few days, and in no circumstances remove a large number of the young shoots at one operation. The top of the tree should be done first, the central part after an interval of two or three days, and the lower portion last.

OUTDOOR VINES.—Vines in the open should be disbudded at an early stage, reducing the buds for a start to two or three on each spur. After an interval of a week or so it will be an easy matter to determine which shoot has the best bunch, and to remove the superfluous ones. Mildew and red spider are the chief pests of outdoor vines in this country, and both should be rigorously combated as soon as detected. For the former employ a good mildew specific, syringing the vines with it in the evening. The syringing should be repeated two or three times if necessary. Red spider can usually be destroyed by syringing with clear water, which may be done on all fine afternoons, taking care that the whole of the foliage is wetted thoroughly. Let the shoots be stopped and fastened regularly, pinching the laterals at about two or three leaves beyond the bunch, according to the space available. The subsequent lateral growths should be stopped at the first leaf. It is impossible to succeed with outdoor Grapes unless the shoots and foliage are kept sufficiently thin to allow the sun to reach every part of the vine.

THE APPLE-BLOSSOM WEEVIL will soon be busy amongst the Apple blossom. Trees that have been neglected in the matter of winter-spraying and cleansing, and have, in consequence, accumulations of lichen and rough bark, are lurking-places for this pest, as will be seen later by the quantities of fallen, damaged fruits under them. Soon after the weevil has entered an Apple blossom the petals turn brown, as if affected by frost. On examination such blooms will generally be found to contain a weevil, or a little hole will be found in the petals, indicating its way of escape. If young trees are attacked some of the weevils may be caught by placing a sheet on the ground under the trees, and shaking the branches sharply on a calm day. The insects are easily dislodged, and will drop on to the sheet, which can be taken up and shaken over the bonfire.

NEWLY GRAFTED TREES.—See that the grafts do not suffer harm from the drying effects of the prevailing east winds. Where clay was used as the grafting medium it should be moistened and the hand passed around it a few times to fill up any cracks.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of
HADDINGTON, Tynninghame, East Lothian.

FRENCH BEANS.—A full sowing of this crop may be made in most localities, choosing a sheltered part of the garden where strong winds will not damage the plants when in full bearing. Strong-growing varieties of the Canadian Wonder type should be afforded a space of about 3 feet between the rows and at least 1 foot between the plants, dropping a bean at every 6 inches, the intermediates to be destroyed when the plants are all up. If the soil is at all heavy do not make a deep drill but a rather shallow one, ridging the soil over the seeds to give them a sufficient covering.

PARSLEY.—As soon as the seedlings are large enough to handle they should be thinned and the thinnings transplanted, allowing a space of about 18 inches each way. The plants will grow into handsome specimens and produce an immense quantity of foliage of the finest quality, for the leaves need not be picked till fairly large, the plants left in the seedling bed at 9 inches apart affording supplies in the meantime. Parsley is sometimes destroyed by a maggot which eats the tap-roots. By making the soil extra firm and then loosening the surface by fre-

quent hoeing the maggots will prove less troublesome, and the Parsley thrives better than in soil of a looser nature. I sometimes save seeds from a selected plant which yields sufficient for a large sowing.

CELERY.—The latest-sown Celery is ready to be pricked out singly. Nothing surpasses a thin layer of compost consisting of half soil and half manure from a spent Mushroom bed into which to transplant the seedlings at 3 inches apart each way. The material should be placed on a cinder bottom. If the seedlings are shaded till established, and watered carefully, at the time for transplanting they may be lifted like grass turves, one mass of roots scarcely any of which need be lost. Plants of the previous batch are beginning to grow freely and will need to be protected only in case of frost being imminent. Should the plants be growing too slowly $\frac{1}{2}$ oz. of superphosphate in each gallon of water will afford the necessary fillip.

WINTER GREENS.—It is the usual practice to sow Savoy, late Cabbages, and Broccoli for late cutting at about this time. I do not find these late sowings give nearly such good results as when the seed is set in April, but then our seasons are shorter in the North. Scotch Kale is a valuable late vegetable which some sow very early, but it is quite early enough to sow it now or a fortnight hence. We are still gathering from a crop sown at the end of last May.

EARLY PEAS.—The plants have grown slower than usual, but provided the weather is genial and water is afforded as required, they will now develop rapidly. To secure a dish at the earliest possible moment pinch the more forward in flower. If rather too close the peas will be small, but they may still be thinned, and the thinnings will be appreciated as flavouring for soups.

SCARLET RUNNERS may be sown in the open quite safely. The plants yield best when trained to tall sticks, but these are not essential, and by allowing the plants a space 3 feet by 3 feet and keeping the shoots pinched they do very well without staking. These Beans crop all the better in rather firm but fertile soil.

THE APIARY.

By CHLORES.

ROBBING.—This is a common trouble during the spring, as well as in August and September, especially in apiaries where syrup feeding has been resorted to. To avoid it, do not spill syrup in the region of the hives, and keep the entrances closed, so that one bee only may escape at a time, and do the work about 4 or 5 p.m. when the apiary is quiet. Do not forget that tits and mice are very busy searching for food, and the former can only be kept in check by shooting, and the latter by trapping, and for this purpose the figure four trap is excellent.

SWARMS.—With the advent of May the apiarist will be looking forward to swarms. Many make the mistake at the initial stage in placing the bees upon the full number of frames, regardless of the number of workers composing the swarm. Our forefathers always placed the bees in a straw skep that was reckoned by its capacity to hold so many pecks, and for this reason had skeps of many different sizes to accommodate swarms of varying strengths. As the colony required more room they gave it by adding ekes. By using only the number of frames that the bees can thickly cover heat is conserved, which is an important detail in successful beekeeping. Beekeepers in Scotland may advantageously purchase English bees, as the swarms are quite a month ahead of those in that country. On receipt of a swarm from a long distance place on the feeder for a few days, and when the weather is too wet for the bees to forage, place on the slow feeder for at least a week, and the results will be far more satisfactory. Wait until the evening before hiving the bees, then toss them out on a platform resting on the entrance, let them pass in, and keep a sharp look-out for the queen, for she might have been injured or even killed in transit.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MAY 11—

United Hort. Ben. and Prov. Soc. Com. meet.

THURSDAY, MAY 14—

Manchester and N. of Eng. Orchid Soc. Ann. Meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 52.3°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, May 6 (6 p.m.): Max. 58°, Min. 50°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, May 7 (10 a.m.): Bar. 29.3; Temp. 61°. Weather—Bright Sunshine.

PROVINCES, Wednesday, May 6: Max. 56°, Cambridge; Min. 50°, Aberdeen.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Hardy Bulbs and Roots at 12; Lilliums and other Bulbs at 3.30; Palms and Plants at 5. At 67 and 68, Cheapside, E.C., by Protheroe and Morris.

FRIDAY—

Orchids at Protheroe and Morris' rooms, at 12.45.

Pitcher Plants.
(See Supplementary Illustration.)

In nothing is the infinite resourcefulness of Nature better exemplified than in the Pitcher Plants, and no plants illustrate better than they the occasional whimsicalness in which she indulges. The common run of plants portray in perfection the amazing and fertile marriage between sober utility and radiant beauty.

Nepenthes and Sarracenias, like the Dionaeas and Droseras, are plants which we should expect to see in a midsummer night's dream rather than in our waking moments. In form and in function alike the Pitchers are amazing. For, whereas in the large majority of plants the leaf-tip soon ceases to grow, in the Nepenthes, it forms the large and cunningly, albeit cruelly, devised traps, wherein over-curious insects find certain death. Every detail of the construction of these traps makes the descent easy and the ascent impossible. The movable lid, when open, and the smoothly-polished incurved edges of the pitcher impress the invitation thrown out to insects by the somewhat livid, almost raw meat-like and mottled colour of the traps. Downward directed hairs, not unlike those in the spathes of Arums, or of Aristolochias, bar egress from the pitchers, and the watery fluid in these vegetable tanks makes drowning easy. That fluid, however, is potent, and possesses the properties of the digestive fluids of animals. Savants have disputed the exact process whereby the remains of intruders are disposed of: some asserting that the active principle of the liquid in the pitcher is identical with that

in the gastric juice of the stomachs of the higher animals: others have maintained that it is closer akin to the protein-dissolving trypsin of pancreatic juice. The truth appears to be that, except for the fact that the juice is alkaline and not acid, as is gastric juice, the pitchers contain a vegetable pepsin. In any case, it is all one to the fly: that luckless visitor, introduced with such pomp and circumstance, takes its lethal bath and the nitrogen locked up in its body finds its way, in course of time, into the tissues of the plant. Therein lies the significance of the pitcher. It expresses the clamant need of the plant for nitrogen. That same need is shown also in the no less strangely contrived traps of Dionaea, and in the effective but less elaborate fly-catching and digesting devices of the Sun Dew (*Drosera*). Strangely enough, the Sarracenias—which are the Pitcher Plants of the Western world, as Nepenthes are of the Eastern—though they have the apparatus, lack the juice for digestion.

No less strange than the existence of these pitchers is the fact that the plants frequently make no use of them. Never shall we forget our surprise when observing Nepenthes in its native habitat to note that the long tendril-like junctions between pitcher and leaf were twisted as often as not so that the pitchers were upside down, and, needless to say, empty. Whether this represented a style of vegetable remorse succeeding a surfeit or whether it was sheer accident we cannot say; but the fact remains that the plant in its native state does not always make use of its formidable insecticidal apparatus.

Nevertheless, there can be no doubt but that Nepenthes merits its name of the grief-assuaging plant, though Linnaeus, who named it, justified his appropriation of Homer's name (see *Odyssey*, book iv., 221) by observing, "If this be not Helen's Nepenthes, it certainly will be for all botanists. What botanist would not be filled with admiration if, after a long journey, he should find this wonderful plant? In his astonishment past ills would be forgotten when beholding this admirable work of the Creator."

It is fit also that Nepenthes should stand alone, the solitary genus of the Nepenthaceae. The curious may find in the pages of the *Gardeners' Chronicle* the original descriptions of many of the species and hybrids. Of the latter not a few of the finest have been raised in this country in the nurseries of Messrs. James Veitch. Indeed, it is no exaggeration to say that our wealth in species and hybrids is due to the enterprise of the members of this firm. An account of that work and of the horticultural history of the genus was published by Mr. (now Sir Harry) Veitch in the *Journal of the Royal Horticultural Society* (xxi., p. 237).

These plants are not very difficult of cultivation, provided they are given adequate heat and moisture. When grown in baskets so that their pitchers are well displayed, they form not only profoundly interesting, but also extremely attractive features of our plant-houses.

In the Supplementary Illustration a natural species, *N. ventricosa*, and a hybrid are depicted:—

*Nepenthes ventricosa** is a native of the Philippines, and *N. × Sir W. T. Thiselton-Dyer* a hybrid raised in the nurseries of Messrs. James Veitch and Sons. *N. ventricosa* was first sent to Kew in 1897 by Mr. C. Ford, at that time superintendent of the Hong Kong Botanic Garden. It was figured in the *Gardeners' Chronicle* of June 18, 1898, and a specimen was shown at an exhibition of the Royal Horticultural Society on October 15, 1901. The length of the pitcher is about 6 inches.

N. Sir W. T. Thiselton-Dyer was raised from a cross between *N. mixta ×* and *N. Dicksoniana* (see figs. in *Gard. Chron.*, January 14, 1893; and November 10, 1888). *N. Dicksoniana* is a hybrid between *N. Veitchii* and *N. Rafflesiana*, and *N. mixta* was the progeny of *N. Northiana* and *N. Curtisii*. *N. Sir W. T. Thiselton-Dyer* is one of the largest and most effective hybrids, the pitchers measuring 8 inches. This fine hybrid was first exhibited at a meeting of the R.H.S. in 1900, and a black-and-white sketch of a pitcher by Mr. Worthington Smith was given in these pages on October 6, 1900.

ANNUAL DINNER OF THE KEW GUILD.—

MR. HERBERT COWLEY sends us particulars of the annual dinner of the Kew Guild, to be held at the Holborn Restaurant on Wednesday, May 20, at 7.30 p.m., when Mr. A. W. HILL, M.A., will preside. At 6.45 on the same evening the annual general meeting will take place in a room adjoining the Caledonian Salon of the same restaurant.

DR. HEMSLEY.—The many friends of Dr. W. BOTTING HEMSLEY, F.R.S., will hear with regret that he has sustained a bereavement in the death of his son-in-law, Mr. E. H. LOVELOCK, of Broadstairs. Dr. HEMSLEY'S daughter, Mrs. LOVELOCK, is well known to many botanists and horticulturists who used the Kew herbarium during the three years when she was employed there on the *Index Kewensis*. Mrs. LOVELOCK is left with three quite young children.

NATIONAL SWEET PEA SOCIETY.—The show of the Irish Rose and Floral Society having been abandoned, the provincial show of the National Sweet Pea Society, which was to have been held at Belfast on July 24, in conjunction with the exhibition of the Irish Society, will not take place. The Sweet Pea Society will therefore not hold a provincial show this season.

GUIDES AT KEW.—The Board of Agriculture again desires to bring to the attention of the public the arrangement established at the Royal Botanic Gardens, Kew, whereby a competent guide accompanies visitors on week-days through the Gardens and explains the many objects of botanical interest. A small charge is made for the services of the guide—6d. for each person attending a morning tour, and 3d. for each person attending an afternoon tour. The present arrangements are of the nature of an experiment, and their continuance beyond September next will depend on the extent of the public demand for the services of the guide. A leaflet giving detailed information on the subject can be obtained on application to the Director, Royal Botanic Gardens, Kew.

* *Nepenthes ventricosa*, Blanco, *Fl. Filip.*, ed. 1, p. 807; Hook., *f.*, in *D.C.*, *Prodr.* xvii., p. 100.

LARGE PITCHER : HYBRID NEPENTHES SIR WILLIAM T. THISELTON-DYER.
SMALL PITCHER : NEPENTHES VENTRICOSA, AN INTRODUCED
SPECIES FROM THE PHILIPPINES.

THE RETURN TO SIMPLER.—It is characteristic of the science of the present day that it becomes less and less dogmatic: whilst holding fast to that which it has achieved, it is more and more alert to recognise that, after all, but little is known. In this chastened spirit, which contrasts sharply with less tolerant phases through which it has passed, science is prepared to admit that many old ideas and customs which it laughed at in years gone by may have in them much that is good and true. Whether science laughs or listens, the wise old woman goes tottering and bent across the field, gathering simples, and in them more than in many panel doctors is her faith. That ancient faith is apparently to be justified by recent works. Not long ago, for example, a doctor, writing in the *British Medical Journal*, was bold enough to advocate the use of Dandelion extract in cases of certain troubles of the digestive system, and he cited from his case-book modern instances in

LEGISLATION AND PLANT PESTS.—A meeting convened by the Horticultural Trades Association to consider proposals put forward at the recent Phyto-pathological Congress at Rome was held in the Lecture Room of the Royal Horticultural Society on Tuesday, May 5. Mr. CUTHBERTSON, President of the Horticultural Trades Association, who was in the chair, announced that the purpose of the meeting was to hear Mr. ROGERS, the chief of the Horticultural Branch of the Board of Agriculture, who had kindly undertaken to give an account of the conclusions arrived at by the delegates at the Rome Congress on Phyto-pathology. Mr. ROGERS gave a lucid and detailed account of these conclusions, the chief of which were summarised in our last issue. The recommendations made by the delegates to their respective Governments involved the scheduling of certain serious pests which attack horticultural pro-

duced will be required, as at present, to pay a fee for the certificate of exemption which will be granted to them. Mr. ROGERS explained the suggestion made by one of the Canadian delegates that an attempt should be made to establish a common agreement between the several Dominions of the Empire with respect to the import regulations of horticultural stock. He mentioned also that the United States were not represented at the Congress, and that it is unknown whether they are likely to subscribe to the proposals. In concluding his summary of the work of the Rome Congress, Mr. ROGERS pointed out that the proposals mark a step towards the simplification of import regulations, and explained that the Board of Agriculture desire to ascertain the considered opinion of those engaged in the export horticultural trade in this country. It is for them to say whether the advantages seem likely to outweigh the disadvantages, and whether it is desirable that the recommendations of the conference be carried into effect so far as this country is concerned. After a discussion, in which Mr. BUNYARD, Mr. PEARSON, Lieut.-Col. Sir DAVID PRAIN, Mr. CHEAL, Mr. HUDSON and Professor KEEBLE took part, the chairman proposed that the subject be referred to a committee, and suggested that members of the Horticultural Trades Association should invite the Royal Horticultural Society to join with them in forming a committee to give the subject fuller consideration, and to report to the Board of Agriculture.

AMERICAN AND ENGLISH SHOWS.—Mr. J. HARRISON DICK, the former editor of the *Journal of Horticulture*, who is now editor of the *Florists' Exchange*, of New York, has given in that journal his impressions of the difference between English and American exhibitions. He draws attention to the advantage of the American method in showing long-stemmed flowers, such as Carnations, in very tall vases, so as to accommodate the whole of the stems, without having recourse to cutting. Roses are also shown in this way in America, while in England there are very few growers who exhibit long-stemmed Roses in tall vases. The New York grower excels in the draping of pillars and in the general overhead effect. Florists' exhibits in the New World are described as much more artistic than here, and specimen Ferns and foliage plants show a good balance in favour of the American grower. On the other hand, the display of Orchids in the London spring show excels the corresponding American exhibition, and in the staging of choice early vegetables the English gardener shows superior skill. There is one domain into which the American gardener has scarcely yet ventured—that of rock gardens and out-door Japanese gardens.

ARBORICULTURE AT THE ROYAL AGRICULTURAL SHOW.—The annual exhibition of the Royal Agricultural Society at Shrewsbury comprises a forestry section which is a feature of increasing interest to visitors. This year an exhibition of trees and shrubs is to form part of the arboricultural exhibit. The specimens shown will consist largely of trees and shrubs imported by collectors from China and elsewhere during the last ten years. Some of the classes in this section will be confined to amateur growers, in order to call forth the exhibition of unnamed varieties. Beside the specimens there will be exhibits of forestry implements, planks, gates, tree-guards, pests (insectivorous and fungous), planting schemes, wood preservatives, and other articles connected with arboriculture. Prizes are offered by the Royal Agricultural Society for the best-managed farms and the best-planted woodlands in the neighbourhood of Shrewsbury, and the results of a hedging competition which was held in February of this year will be on view.

FIG. 140.—PLANT OF NEPENTHES, TO SHOW HABIT OF GROWTH.
(See Coloured Plate.)

which this ancient remedy had proved of remarkable efficacy. Yet more recently another doctor contributed to the *Lancet* testimony of the value of raw Potato juice in alleviating pain and in reducing swelling in cases of synovitis. The value of an application of this extract in the form of ointment or liniment was demonstrated in several cases, and applications are recommended in the case of gout, lumbago, rheumatism, or of bruises. In acute cases the juice is made up with hot water and used as a fomentation or poultice, and it is said to relieve pain in gouty sufferers more quickly than does any other specific in present use. The active agent of the Potato juice is unknown; but here again medicine is less impervious than it was wont to be, and recognising that all knowledge is to a greater or less extent empirical, does not disdain to use that which is wholly so. It is tempting to wonder whether, after all, there may not have been some virtue in the raw beef which we used to apply to a black eye.

duce. Each nation is to draw up its own list of such pests, and it is hoped that those nations who come into the agreement will find themselves relieved from the necessity of inspection at the port of entry. In any case, it is hoped that such inspection, if experience proves that it must be maintained, will be less vexatious than it is at the present time. In lieu of inspection at the port of entry there will be established by the nations subscribing to the decisions of the congress a system of nursery inspection. On the basis of this inspection certificates will be issued guaranteeing that the exported stock is free from the diseases specified. As a corollary to such a system of inspection it will be necessary to establish inspection not only of the nurseries engaged in export business, but also of all nurseries engaged in raising plants liable to be attacked by the scheduled pests. This inspection, being a national affair, will be carried out without charge to the nurserymen who are not engaged in export business, but those who are so

A NEW MUSHROOM.—According to a communication made by Prof. BONNIER to the Academy of Science, and reported in *Le Jardin* (April 20), MM. CONSTANTIN AND MARTRUCHOT have shown that le Pied Bleu, *Tricholoma nudum*, a "Mushroom" which is much appreciated as a delicacy and obtainable in nature only from October to December, may be cultivated in dark chambers at a temperature of 11° C. (52° F.), and made to give good crops all the year round. The mycelium is grown on beds of Beech leaves, and under this system of cultivation it produces enormous heads, which instead of preserving the blue-violet colour characteristic of the fungus become almost white. The fungus may be propagated from year to year by means of mycelial hyphae taken from the bed.

LYONS INTERNATIONAL URBAN EXHIBITION.—This exhibition will be open from May 1 to November 1 next, and in conjunction therewith will be held three temporary horticultural shows. The dates of these will be June 5 to 9, September 4 to 9, October 21 to 27. Horticultural products have eight classes allotted to them at each show, and are as follows:—(1) Fruit trees; (2) ornamental trees and shrubs; (3) Roses; (4) open-air floriculture; (5) greenhouse floriculture; (6) market garden produce; (7) horticultural arts and industries, garden plans, horticultural instruction, and garden publications; (8) the floral decorations of towns and houses. Entries must be sent by May 15 for the first show, addressed to the Commissaire Général of the Horticultural Commission.

INSECT VISITORS TO SUNFLOWERS.—Mr. THOS. D. A. COCKERELL, of the University of Colorado, Boulder, Colorado, is making a study of *Helianthus*, and intends to publish an exhaustive work on the genus. One matter of considerable interest is the relation of the flowers to insects. In America, where Sunflowers are indigenous, a multitude of different insects visit and feed on them, and the question is asked, how soon, and to what extent, do insects in other countries take to them? It is a case of adaptation, of considerable general interest, and as Mr. COCKERELL is particularly desirous of getting *English* records on the subject, he will be very glad if English readers will send him the results of their observations, positive or negative. The chief points to be noted are:—Do insects or other creatures injure Sunflowers? (State what kind of Sunflowers.) Do bees and butterflies visit the flowers? If so, are the visits frequent or rare? What kinds of butterflies? And so forth. Such information is not difficult to collect, as these points can often be noted in going about the garden, if the idea is present in the mind.

A NEW COVER CROP.—Under the above title Mr. W. G. CRAIB describes in the *Kew Bulletin*, No. 2, 1914, the use of *Dolichos Hosei* as a cover crop in rubber plantations. The species, which is new to science, has the necessary qualities for this purpose. It is a low-growing leguminous plant, may be dug into the soil and reproduces itself in time to check the growth of weeds. *D. Hosei* is a native of Sarawak.

ROYAL COUNTIES AGRICULTURAL SOCIETY.—The annual show of this society will be held at Portsmouth, on Southsea Common, from June 10-13. A flower show will be again held in connection with the exhibition, and is being organised as usual by Mr. C. S. FUDGE, secretary to the Southampton Royal Horticultural Society. We understand the promises of entries up to date insure a very good exhibition.

ENTOMOLOGICAL SPECIMENS WANTED.—Dr. A. D. IMMS, Entomological Dept., The University, Manchester, is making a study of the parasites of the mussel scale, and would be grateful to any readers who will send him

specimens of Apple branches badly infected with this scale insect. The branches should be cut about 18 inches long, and their ends sealed with paraffin or grafting wax. They may be sent loosely packed in straw, and enclosed in a wooden or cardboard box. Any expenses will be refunded if necessary, and boxes will be sent for packing the specimens.

A GOOSEBERRY-BLACK CURRANT HYBRID.—In his notes on new shrubs, Mr. W. J. BEAN (*Kew Bulletin*, No. 2, 1914) gives an account of a Gooseberry-Black Currant hybrid, *Ribes wollense*, raised by Mr. W. J. BELL, of The Woll, Hawick, N.B. As Mr. BEAN points out, a similar hybrid, *R. Culverwellii*, described in *Gardeners' Chronicle* (May 19, 1885), was raised about 1880 at Thorpe Perrow, in Yorkshire; and another, *R. Schneideri*, is described in *Gartenflora* for 1902. *R. wollense* is, however, distinct from either of these, and appears to have originated by natural means. The hybrids, of which some dozen bushes are growing in Mr. BELL'S grounds, are very old plants, and one of them has a main stem 12 in. in girth. *R. wollense* is perhaps nearer to *R. Grossularia* than to *R. nigrum*, especially in foliage and flower; but its fruit is black, smooth, of the same size as and similar in flavour to that of the Black Currant.

HOME CORRESPONDENCE.

IN A SCOTTISH MANSE GARDEN.—During the past month, *Prunus pissartii* has been splendidly effective; and I am not without hope of this tree setting some of its fruit, as it has done in previous mild seasons. But as its flowers are dark purple—almost the colour of the leaves—from the earliest stage of their evolution they are almost certain to be nipped off the branches quite prematurely by rapacious birds. *Pyrus Malus floribunda*, with its roseate flowers, festoons the slender, pendulous boughs. When I visited Logan Garden in this peninsular parish on April 21, such *Magnolia* as *stellata*, *M. conspicua* and *M. Soulangiana* were already in glorious bloom. In the centre of my garden, which is at least equally sheltered, *Magnolia Watsonii*, planted fully fifteen years ago, is by far the most attractive flowering tree. It is valuable by reason not only of its almost peerless grace, but the odorous fascination of its impressive flowers. *M. macrophylla*, which I also possess, has, I have been informed, even in its native North American habitats (Carolina and Louisiana), a peculiar characteristic of not flowering till it reaches its utmost height; and this has been confirmed by my own experience. Plums, Cherries, Apples and Pears have an abnormal profusion of bloom this season, and should be unusually successful, unless unfavourable atmospheric visitations intervene. Last year, in almost every region of Scotland, the crops were much injured by a storm of exceptional violence in May. The first Apple in flower here is the Irish Peach, whilst Denniston's Superb Greengage, an invaluable variety, is the earliest Plum. Among the Roses that are farthest advanced—some of them with their flower-buds already half-grown—are Captain Hayward, British Queen, Old Gold, Viscount Carlow, Margaret Dickson, G. B. Clark, Clio, Enchantress (a charming garden Rose), Rosa Harrisonii, Laurette Messimy, Frau Karl Druschki, and the Waltham Bride. Oriental and American Lilies are developing rapidly, especially *L. Henryi*, *Szovitzianum*, *auratum platyphyllum*, *candidum*, *pardalinum* var. *Burbankii*, *Washingtonianum*, *longiflorum giganteum*, and *speciosum magnificum*. *David R. Williamson*, *Manse of Kirkmaiden*, *Wigtownshire*.

LA TAILLE LORETTE (see p. 249).—It has long been the custom of French gardeners to cut back the stipulary buds on cordon and fan-shaped trees, though this is not the principle of the "Taille Lorette." It has been resorted to (1) when a shoot has become too strong, thus threatening to destroy the symmetry of the tree; (2) when a shoot has grown too close to the leader; (3) in order to obtain exactly two buds, to form an "étage" in a fan—though in this case there was always the risk of having one

shoot stronger than the other, as in the case of the two stipulary buds. M. Hardy, the first Director of the "Ecole Nationale d'Horticulture de Versailles," was an upholder of the summer pruning method (*i.e.*, the second week in August), stating as his reason that at that time of the year growth was not sufficiently strong to force the buds, and they would be well established by the following season. It is regrettable that there are in English no equivalents for the French words "Brindelles, dards, coursons, bourses, onglets"; but there are technical terms which are capable of expressing the exact position or condition of any shoot. *P. Aquatias*, *Stockport Road, Timperley*.

WASPS.—Referring to the paragraph headed "Wasps" in your "Answers to Correspondents" on page 308, I have, with eight glass jam jars half filled with beer and sugar, accounted for 182 queen wasps to date at a cost of less than 12s., equalling about 3d. per wasp. My garden is about three acres, surrounded by a paddock of some thirty-five acres, containing a good deal of timber. I have also by this method caught many hundreds of flies, which not having, I suppose, yet shed their eggs, has accounted for many millions of flies. By this method of syrup catching your hint not to catch too many queen wasps is somewhat neutralised. *R. Oswald Fordham, Broom Hall, Biggleswade*.

OFFSETS OF HIPPEASTRUMS (see pp. 270, 302).—Mr. C. R. Fielder will be interested to hear that I have for many years grown several fine plants of *Hippeastrum* from offsets from bulbs which were themselves originally offsets, and I have frequently noticed the same thing occurring among plants belonging to fellow gardeners. When I read in your columns the report of Mr. Fielder's lecture, and his remark in regard to an offset not producing an offset, I was much surprised. At the present time I have a few very strong bulbs, originally offsets, growing in 9½ inch pots, with two or three offsets on each, growing vigorously. I have often considered that many growers make a mistake in affording *Hippeastrums* too much heat. Some of the strongest and healthiest plants I have seen were grown in a house from which frost was only just excluded. The plants are grown here under very cool and simple conditions. *Wilmot H. Yates, Rotherfield Park Gardens, Hampshire*.

THE LESSER NARCISSUS FLY (EUMERUS LUNULATUS) (see pp. 240, 272, 302).—The finding of *Emmerus* larvae in a rotting Iris rhizome, which Mr. Shea practically ignores (see p. 302), is, I think, something more than a "so-called" fact—it is a new and very significant fact. It is also beyond doubt that there is more than one brood of flies in a year. I have hatched out flies in April and again in August and September. It is a reasonable deduction that the larvae found in a bulb in the spring should be from eggs laid by the later and not by the first brood, which is about now. It is not suggested "in support of the scavenger theory," for as a matter of fact it does not directly affect that question. It is simply intrinsically probable. If the August brood are the progeny of the April brood it would of course be a certainty, but so far as I know that has not yet been actually proved. To cope with and eradicate a pest it is essential to have a complete knowledge of its life-habits. Until we have proof it would therefore be very unwise to assume that it lays its eggs on the leaves only. It is important to find out whether it may also lay its eggs after the leaves are gone, and if so, how the flies on the grubs find their way to the bulb. And this applies, I feel sure, to the Merodon also. What Mr. Shea appears to have lost sight of is that the view of the *Eumerus* which he upholds—that it attacks and feeds on the living bulb—is every whit as much an unproved theory as that it is a scavenger. As far as the facts are concerned it has no other grounds of support than "post hoc, propter hoc"—larvae have been found in Daffodil bulbs, therefore they were feeding on the living tissue. A crude, unscientific deduction. On the other hand there is the newly ascertained fact already noted. Since, however, as Mr. Shea very truly says, so little is really known about the matter, our proper attitude

SOCIETIES.

ROYAL HORTICULTURAL

TUESDAY, May 5.—The usual fortnightly meeting was held on Tuesday last in the Vincent Square Hall, Westminster. There was a large exhibition, and both the annexes were required to find space for the exhibits. It was mainly a Tulip show, for not only did the National Tulip Society hold competitive classes on this occasion (see p. 322), but growers took the opportunity to exhibit collections of these flowers. A Gold Medal was awarded to Messrs. BARR AND SONS, and a Silver-gilt Flora Medal to Mr. WATTS, of St. Asaph. The Narcissus and Tulip Committee recommended two First-class Certificates to varieties of Tulips.

The principal exhibits before the Floral Committee consisted of Roses, Carnations, flowering trees and shrubs, Sweet Peas, Calceolarias, Schizanthus, and hardy plants. This body recommended two First-class Certificates, and five Awards of Merit to novelties.

There were fewer collections of Orchids than usual, but plenty of novelties were forthcoming, and the Orchid Committee recommended two First-class Certificates and three Awards of Merit.

The Fruit and Vegetable Committee again found very little to do. There was only one group, a collection of Onions. Mr. BENNETT-POE showed a large bunch of home-grown Lemons, for which a Cultural Commendation was awarded. An award of merit was made to a new variety of Apple, subject to an inspection of the tree (to ascertain its habit, etc.) by a deputation of the Committee.

Floral Committee.

Present: H. B. May, Esq. (in the chair), Messrs. G. Reuthe, W. A. Bilney, C. E. Shea, J. Dickson, H. J. Jones, Chas. Dixon, Thos. Stevenson, J. W. Moorman, John Green, J. Jennings, Chas. Blick, J. W. Barr, W. Bain, C. R. Fielder, Geo. Paul, R. Reginald Nevill, W. P. Thomson, R. Hooper Pearson, James Hudson, Arthur Turner, W. Howe, W. Cuthbertson, F. Page Roberts, Ed. Mawley, F. W. Harvey, R. W. Wallace, Chas. E. Pearson, E. H. Jenkins, and J. F. McLeod.

AWARDS.

FIRST-CLASS CERTIFICATES.

Rhododendron × *Loderi* "Diamond."—Under this name was shown a reputed hybrid between *R. Aucklandii* and *R. Fortunei*. In foliage and form of flower it resembled the former parent, but in the size of truss and individual bloom it represented a great advance. The flowers were over 6 inches in diameter, and were sometimes developed in a cluster of as many as twelve together. The colour is almost pure white, but the buds and young flowers show a suffusion of flesh pink. The bells are broadly expanded and of fine texture, and plants shown were obviously vigorous and floriferous. The best developed leaves that we observed were 12 inches in length by 3½ inches in breadth, and the under surface is slightly glaucous.

Rhododendron × *Loderi* "Pink Diamond."—This appeared in every respect identical with the last except in colour, which in this is a pretty shade of soft pink. In a series of trusses of the two forms, however, showing flowers in different stages of development, it was difficult to draw a definite boundary between Diamond and Pink Diamond. These two were shown by Sir E. LODER from the open ground at Leonardslee, Horsham.

AWARDS OF MERIT.

Rhododendron "Gill's Goliath."—This is a very fine seedling with rose-pink flowers, 4 inches or more in diameter, held in trusses of 12 to 14 blooms. The colour is distinctly richer towards the edges. This was stated to be a hybrid between *R. Aucklandii* and *R. Thomsonii*, but we saw very little evidence of the latter parent. The leaves are lanceolate, sometimes as much as 10 inches in length by 2 inches in breadth, of a leathery texture, but not at all glaucous. Shown by Messrs. R. GILL AND SONS.

Auricula "Majestic."—A large-flowered Alpine variety of the florists' *Auricula*. The colour is

a crimson-brown, almost maroon, with a darker belt especially noticeable in the young flowers when the rim is pale, round the large yellow eye. Shown by Messrs. PHILLIPS AND TAYLOR and Messrs. J. VEITCH.

Iris "Isolda."—This and the next are the best of the recent additions to the garden forms of the *Regelio-Cyclus* group. The flowers are coloured light bronze, lightly suffused with purple and richly covered with a beautiful network of purple-brown veins. At the lateral edges the falls show a lighter shade of bronze, but the throat below the beard is heavily blotched with black, which is drawn out in deep veining almost to the tip of the fall. This colour scheme is almost identical with that of the variety *Charon*, which is already in commerce, but *Isolda* has better form.

Iris "Leucothaea."—In size this is one of the finest of the group. The colouring is a rich mauve-purple overlaid with a network of darker tint. The fall shows a small black throat blotch, on a body colour like that of the standards, and showing the same rich intricate venation and dotting. To be fairly appreciated these glorious Irises need to be seen in full sunshine, when their flowers become almost translucent. These two were shown by C. G. VAN TUBERGEN, junr., Haarlem.

Syringa reflexa.—A distinct new hardy Lilac from China. The habit is bolder, the leaves larger, and the growth more rigidly erect than in *S. vulgaris*, but its chief distinction is in its inflorescence, which is drawn out in a crowded tapering arching spray, sufficiently remarkable in form to have given the species its name. The colour is soft pink, still paler in the expanded blooms, which are only one-third of an inch in diameter. The flower sprays were about 6 inches in length by 2 in diameter, but developed specimens should prove much larger. The leaves are thin in texture, and reach 5 inches in length by 2 inches in breadth. Shown by the Hon. VICARY GIBBS (gr. Mr. E. Beckett).

OTHER NOVELTIES.

Rhododendron Willmottiae (Wilson's No. 882).—A charming addition to the Alpine *Rhododendrons* introduced from China through E. H. Wilson. Showy white or pale cream flowers were borne quite freely on a bushy plant 6 inches high, and the young foliage was prettily tinted with bronze. The plant was shown by Miss WILLMOTT, who also exhibited *Androsace Henryi*, a plant which has proved very difficult to raise.

Iris minuta.—Mr. AMOS PERRY showed flowers of this smallest and least conspicuous of Irises. It is a Japanese species, and grows about 2 inches in height, with flowers ½ inch across. There is a long account of it in *The Genus Iris*, and it is of considerable botanical importance.

GENERAL EXHIBITS.

Mr. E. J. LUCAS, Horsham, showed flowering sprays of *Plagianthus betulinus*, *Distylum racemosum*, *Paulownia imperialis* and *Edwardsia macrantha*, all from the open.

One of the finest floral exhibits was a group of *Schizanthus* exhibited by Mrs. STEWART MACKENZIE, Lydhurst, Haywards Heath (gr. Mr. Evans), for which a Silver-gilt Banksian Medal was awarded. This exhibit was composed of large, shapely plants that were literally masses of bloom.

Lady PAGET, Warren House, Kingston Hill (gr. Mr. Figgis), exhibited a group of the bright yellow-flowered *Calceolaria Clibranii*, for which a Silver Banksian Medal was awarded.

From the JOHN INNES HORTICULTURAL INSTITUTION, Merton, were displayed hybrid *Calceolarias*. The finest, from a garden point of view, was a cross between *C. angustifolia* and *C. plantaginea*. The plant is about 2 feet high, and bears a large number of spreading trusses of rich yellow flowers. Another variety of merit somewhat resembles *Bronze Age*. It is the progeny of *C. angustifolia* and a greenhouse *Calceolaria*.

MESSRS. JAMES VEITCH AND SONS, LTD., King's Road, Chelsea, showed magnificent plants of greenhouse *Azaleas*, choice *Hippeastrums*, *Kalanchoe flammea*, *Swainsonia galegifolia*, and a group of *Auriculas*. As a floor group this firm showed baskets of Alpines arranged with flower-

should be that of the open mind. It is in that spirit I have been in correspondence for some time past, urging that the matter should be cleared up by someone who could devote the time to it, and I had already sent all my stock of *Merodon* and *Eumerus* grubs for such an investigation before Mr. Shea's communication to the R.H.S. Scientific Committee appeared. Pending the results of such investigation there is only one other point raised that appears to be of interest. Mr. Shea bases his view chiefly "by what is called analogy" on the fact that *Merodon* and *Eumerus* are closely allied, arguing that therefore their habits would probably be the same. Judging from the diversity of habits of many familiar insect species that are more or less closely allied, I should have thought that that was a very unsafe deduction. It would be of interest if an entomologist would state how closely they are really allied, and on what grounds. Since their habits are still a matter of debate, it must be on purely morphological grounds. Yet to ordinary observation they appear very different (both larvae and flies), not only in size but form. A. J. Bliss.

FROST AND THE FRUIT CROPS.—On the morning of May 2 this district experienced 14° of frost and a keen north-east wind which have caused great damage to Plum, Cherry, Strawberry and Apple blossom. Even the undeveloped Apple bloom is quite black. The young leaves of Oak trees, which are earlier in this district than they have been for many years past, are shrivelled like brown paper, and the foliage of many other forest trees is similarly affected. Many tender herbaceous plants are cut down, whilst Cabbages, Savoys, and Cauliflowers in the seed beds are completely destroyed. Young Turnips and Peas are likewise harmed. The great amount of damage may be owing to the keen wind which attended the frost, as the ground at the time was perfectly dry, although, as Chatsworth is close to the river, atmospheric moisture may have contributed. I have never in my experience seen greater damage wrought by the same amount of frost or so great a range of plant life affected as in this case. F. Jennings, Chatsworth Gardens, Chesterfield.

—The severe frost in the early hours of the 2nd inst. caused widespread damage to the fruit crops in the Vale of Evesham district. The frost, which varied from 6° to 9° in different places, and was most severe from 2 to 5 o'clock, caused great damage to the underground crops. Almost everywhere early Potatos and Runner and Dwarf Beans were cut down, and a large acreage of Peas was laid flat. Although the fruit trees were dry and well protected with the leaf they have suffered very severely, especially in some low-lying places, where Plums appear to have been completely destroyed. Before Saturday morning there was a remarkably fine promise of fruit, and the trees were healthy and growing well after the warm and sunny April. Some unfortunate growers have very little fruit left on their trees. In many cases 90 per cent. of the Plums have been killed. The Apple trees were in bloom, and it is difficult yet to say whether they were much damaged, but they will be checked in their progress. The loss to Strawberry growers will also be great. Almost everywhere the first bloom, which always produces the finest Strawberries, has been killed. F. P.

PEACH LEAF CURL.—In reading the paragraph on this fungous disease by Mr. J. G. Weston, p. 299, I notice that he does not prescribe a remedy for this pest. We were formerly much troubled by Peach leaf curl, but during the past two years it has not developed, thanks to timely spraying with the Bordeaux Mixture, which in our case has proved an excellent preventive. The trees should be sprayed immediately before the blossoms expand, and again when the fruits are set. The result is that the trees make perfectly healthy growth. We employ 2 lb. of sulphate of copper and 2½ lb. of ordinary washing soda to 10 gallons of water for the first spraying, and for the second application the water is increased to 12 gallons. This specific is quite harmless to the young foliage. J. Gardner, Batsford Park Gardens, Gloucestershire.

ing trees. *Aquilegia flabiata nana alba* (see fig. 141), *Euphorbia polychroma*, *Saxifraga bathoniensis*, and *Trillium grandiflorum* were all uncommonly good. (Silver-gilt Banksian Medal.)

Messrs. STUART LOW AND Co., Bush Hill Park, Enfield, exhibited Carnations and Roses, for which a Bronze Banksian Medal was awarded. There were fine blooms on long stems of Roses Frau Karl Druschki, Lady Hillingdon, Liberty, Mrs. John Laing, Molly Sharman Crawford, and other well-known sorts.

Messrs. H. B. MAY AND SONS, Edmonton, filled a large table with flowering plants and Ferns. Their Hydrangeas were notable for the fine colouring in rose and blue shades; Verbenas, Clematis and Violas were shown well. (Bronze Flora Medal.)

Messrs. DOBBIE AND Co., Edinburgh, and Marks Tey, Essex, showed Sweet Peas of splendid quality, for which a Silver Flora Medal was awarded. The varieties included Inspector, Thomas Stevenson, New Marquis, Dobbie's

Hillingdon, Fisher Holmes, Lady Reay, Avoca and others were arranged in the boxes.

Messrs. FRANK CANT AND Co., Colchester, also exhibited Roses, for which a Silver Flora Medal was awarded. Besides standards in pots and pillar varieties, there was a choice selection of cut blooms in exhibition boxes.

Messrs. PAUL AND SON, Cheshunt, showed Roses and flowering trees and shrubs, for which a Silver Banksian Medal was awarded.

A very pretty White Rambler Rose was exhibited by the Rev. J. PEMBERTON, Havering, Romford, under the name of Pemberton's White Rambler. It appears to be a white form of the well-known Crimson Rambler.

Messrs. J. CHEAL AND SONS, Crawley, showed sprays of flowering trees and shrubs. The flowering Cherries were exceedingly beautiful, especially the one named Kigansakua. The hardy *Azalea Maxwellii*, *Laburnum Vossii*, *Genista purgens*, *Viburnum Mariesii* and *Pyrus Malus Scheideckeri* were also noticed.

Mr. CLARENCE ELLIOTT, Stevenage, was awarded a Bronze Flora Medal for Alpines, exhibited on a neat rockery, the most conspicuous plants being *Gentiana acaulis*, *Primula involucrata* and the pretty dwarf *Phlox subulata* Vivid.

Mr. G. W. MILLER, Wisbech, showed hardy flowers which included two remarkable varieties of *Viola gracilis*, the one named Golden Treasure (yellow), the other *magnifica* (rich purple). In both cases the blooms were as large as those of ordinary bedding Violas.

Mr. M. PRICHARD, Christchurch, showed varieties of *Scilla nutans* and *S. campanulata*, with other hardy flowers. (Silver Banksian Medal.)

Messrs. G. AND A. CLARK, LTD., Dover, showed fine flowers of *Iris Susiana*, *Onosma alba rosea* and *Gentiana acaulis alba* in a collection of hardy flowers.

Messrs. PHILLIPS AND TAYLOR, Bracknell, were awarded a Bronze Flora Medal for hardy flowers and Auriculas.

The showy St. Brigid Anemones were exhibited by Messrs. REAMSBOTTOM AND Co., Geashill, King's Co., and Messrs. GILBERT AND SON, Dyke, Bourne.

Hardy flowers were also shown by Messrs. GEO. JACKMAN AND SON, Woking; the Misses HOPKINS, Mere Gardens, Shepperton (Bronze Banksian Medal); Mr. JAMES BOX, Haywards Heath (Silver Flora Medal); Messrs. GEO. BUNYARD AND Co., LTD., Maidstone; Messrs. JOHN WATERER, SONS, AND CRISP, LTD., Twyford; GUILDFORD HARDY PLANT NURSERY; Messrs. R. TUCKER AND SONS, Oxford; Mrs. LLOYD EDWARDS, Bryn Oerog, North Wales (Bronze Flora Medal); Mr. H. HEMSLEY, Crawley; Mr. G. REUTHE, Keston, Kent (Bronze Banksian Medal); Messrs. T. S. WARE, LTD., Feltham; Mr. L. R. RUSSELL, Richmond; Mr. REGINALD PRICHARD, Wimborne; and Messrs. J. PIPER AND SONS, Bayswater (Silver Banksian Medal).

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair, and Messrs. Jas. O'Brien (hon. secretary), Gurney Wilson, W. Bolton, F. Sander, R. G. Thwaites, F. M. Ogilvie, T. Armstrong, A. McBean, W. Cobb, J. Charlesworth, W. H. Hatcher, J. E. Shill, H. G. Alexander, G. Hunter, W. P. Bound, Arthur Dye, E. H. Davidson, F. J. Hanbury, C. J. Lucas, Stuart Low, De B. Crawshaw, R. A. Rolfe, W. H. White, S. W. Flory and Sir Harry J. Veitch.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum crispum *The Baroness*, from Baron BRUNO SCHRODER, The Dell, Englefield Green (gr. Mr. J. E. Shill). This is the noble form for which an Award of Merit was obtained on June 17 last year, and now grown to a marvellous state of perfection. The heavy spike bore flowers of great size and beauty. The ground colour is white, heavily tinged with purple at the back, and blotched with a light shade of violet, the fringed margins of the petals and spaces between the blotches white. Lip white, with a chestnut blotch in front of the yellow crest.

Odontoglossum Helmath (parentage unrecorded), from Baron BRUNO SCHRODER. A grand dark flower of the O. illustrissimum class; the segments are claret red with a slight golden hue, the margins and tips bluish-white.

AWARDS OF MERIT.

Bulbophyllum Fletcherianum (n. sp.) (see fig. 142), from the Rev. J. C. B. FLETCHER, Mundham Vicarage, Chichester. This is a very remarkable *Bulbophyllum* from New Guinea, which was originally in the possession of Mr. E. V. Low, but is now shown in flower for the first time. The large bronzy-purple pseudo-bulbs have a granulated surface, the fleshy, decumbent, oblong-ovate leaves nearly 1 foot in length, purplish-green, with a glaucous covering. The seven-flowered inflorescence is a short raceme, each flower having a large bract. The broadly lanceolate upper sepal is 2 inches long, claret-coloured, speckled with white; the lateral sepals, 4 inches

FIG. 141.—AQUILEGIA FLABIATA NANA ALBA.

Cream, King White, Dobbie's Scarlet and Royal Purple.

A large exhibit of *Streptocarpus* in variety was shown by Messrs. JOHN PEED AND SON, West Norwood. (Silver Banksian Medal.)

Messrs. R. GILL AND SONS, Falmouth, again showed trusses of *Rhododendrons*, and remarkably well-flowered sprays of *Embothrium coccineum*. (Bronze Flora Medal.)

Miss MANGLES, Littleworth Cross, Seale, Farnham, showed trusses of *Rhododendrons* from her choice collection of these beautiful flowering shrubs.

Messrs. B. R. CANT AND SONS, Colchester, were awarded a Silver-gilt Banksian Medal for Roses. This very meritorious exhibit was backed with pillar varieties, standards being arranged in front of these, and a front row of large exhibition blooms in boxes. A standard plant of White Dorothy especially appealed to us, as also did the Austrian Copper and Austrian Yellow varieties. Choice single blooms of *Gloire de Chédane-Guinoisseau*, Hugh Dickson, Lady

Carnations of the Perpetual-flowering type were exhibited by Messrs. ALLWOOD BROS., Wivelsfield, Haywards Heath (Silver Banksian Medal); Mr. C. ENGELMANN, Saffron Walden (Silver Banksian Medal); and Mr. H. BURNETT, Guernsey (Silver Banksian Medal).

Messrs. CARTER, PAGE AND Co., London Wall, showed Dahlias, Violas and annuals.

Messrs. WILLS AND SEGAR, South Kensington, showed East Lothian Intermediate Stocks and Ericas.

Mr. A. H. COLE, Swanley, exhibited bunches of Zonal-leaved *Pelargoniums* and *Paeony*-flowered Dahlias.

Mr. JAMES DOUGLAS, Great Bookham, was awarded a Silver Banksian Medal for Auriculas and a large specimen of *Myosotidium nobile*, like a giant Forget-me-not.

Mr. AMOS PERRY, Enfield, displayed hardy flowers, including the yellow form of *Viola gracilis*, novelties in Oriental Poppies, varieties of *Onocyclus Irises* and *Sarracenia Drummondii* in flower.

long, are narrower, connivent or folded, the base almost enclosing the labellum, claret colour, with some small light spots; the 1 inch long petals and smaller lip are bright claret-red. In texture and colouring it resembles a *Stapelia*. It is a species standing alone, but the flowers are in some respects nearest to *B. longisepalum*, but the flowers of this latter species are borne singly on tall scapes.

Cypripedium macranthum album, from Mr. G. REUTHE, Fox Hill Hardy Plant Nursery, Keston. A true albino of the large, rose-coloured and hardy *Cypripedium macranthum*, the flower being pure white without a trace of colour.

Oncidioda Mauricei (*Oncidium tigrinum* × *Cochlioda vulcanica*), from Monsieur H. GRAIRE, Amiens, France. A remarkable bigeneric hybrid which well indicates both parents, although the *Oncidium* predominates. The erect inflorescence has many flowers 2 inches in length; the sepals and petals are dull purple; the lip, which has the side lobes distinctly divided, and the front developed on an isthmus, primrose yellow.

GENERAL EXHIBITS.

Lieut.-Col. Sir GEO. L. HOLFORD, K.C.V.O., Westonbirt (gr. Mr. H. G. Alexander), showed the brilliant scarlet *Odontioda Chanteleer* Orchidhurst variety, which obtained a First-class Certificate, May 20, last year; and *O. Chanteleer* Westonbirt variety, a larger form, of a glowing scarlet colour, the flowers being of fine shape. Also very finely grown *O. Vuylstekeae*, *O. Bradshawiae* and *Miltonia* White Admiral, with large milk-white flowers with pale lilac-coloured mask.

The Hon. Lady NEELD, Grittleton, Chippenham (gr. Mr. Pitts), sent *Odontioda* Diana Grittleton variety, with a spike of 25 dark red flowers.

Mrs. NORMAN COOKSON, Oakwood, Wylam (gr. Mr. H. J. Chapman), sent *Odontoglossum illustrissimum* Cookson's variety, a large and perfect flower, prettily marked; and *Odontioda Vivienne* (*Odm. crispum* Britannia × *Oda. Cooksoniae*), with Indian red spotting on the lilac-tinted sepals and petals.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed a still further advance on his famous strain of *Odontoglossum* Queen Alexandra and *O. harvengtense*, both superb flowers; the new *O. Bellamina* (*bellatulum* × *ardentissimum*) and *Odontioda rosefieldiensis* Crawshayana, two of which had previously secured Awards of Merit.

F. M. OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), showed the unique *Odontoglossum* Harwoodii Shrubbery variety and *O. Iorisianum aureum* (*triumphans aureum* × *luteo-purpureum* *Vuylstekeanum*), true to its parents in its two shades of yellow.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), staged an interesting and extensive group in which rare species and hybrids were well represented. *Miltonia vexillaria* were well displayed, with various pretty seedling *Odontoglossums*, *O. Wiganianum*, *O. crispum* Harryanum, *O. Souvenir de Victor Hye de Crom*, *O. crispum* Flambeau, *O.-C. Stamfordianum* and other blotched forms; *Zygopetalum* Cecil Rhodes and a pretty hybrid of *Z. Perrenonii* well displayed their violet labellums; *Brasso-Cattleya* Digbyano-Mossiae, B.-C. Rova and other *Brasso-Cattleyas* and choice *Cypripediums*. (Silver Flora Medal.)

Messrs. STUART LOW AND CO., Bush Hill Park, and Jarvisbrook, Sussex, had a beautiful group, the numerous plants of their fine strain of the large white *Dendrobium Jamesianum*, which formed the body of the group, contrasting well with the many tall sprays of bright red *Renanthera* *Imshoottiana* arranged above them. (Silver Flora Medal.)

Messrs. HASSALL AND CO., Southgate, staged a good group in which the forms of *Cattleya Schröderae* were excellent, one white variety being specially attractive. In front were six well-flowered specimens of the fragrant white *Trichopilia* *Backhouseana*, also good *Laelio-Cattleya* *bletchleyensis* and L.-C. Lydia. (Silver Banksian Medal.)

Messrs. CHARLESWORTH AND CO., Hayward's Heath, had a group of splendidly-grown specimens, including their large red *Odontioda* *Hippolyta*, *O. Madeline*, two forms of *O. Royal*

Gem, and other *Odontiodas*; *Miltonia* *Charlesworthii*, with its large ruby-crimson mask on the lip; *Cattleya* *Schilleriana*, *Chysis* *langleyensis*, and some good *Odontoglossums*.

Messrs. FLORY AND BLACK, Slough, staged a group of hybrids, the best of which were *Laelio-Cattleya* *Dominiana* *alba*, with pure white sepals and petals, the latter having a slight tinge of purple on the tips, the labellum bright violet-purple with gold lines at the base, contrasting effectively with the white petals; and the richly coloured L.-C. *Invincible*. L.-C. *Bellata* (*Bella* × *purpurata*) has large silver-white flowers tinged with lilac, and with a dark purple lip; L.-C. *Deciata* (*Decia* × *purpurata*) is an improvement on L.-C. *Decia*. Other hybrids, including *Disa* *Luna*, were also shown.

E. H. DAVIDSON AND CO., Orchid Dene, Twyford, sent *Sophro-Laelio-Cattleya* *Dorila* var. Mrs. Hatfield (*S.-C. Doris* × *L. pumila*), a pretty

Narcissus and Tulip Committee.

Present: E. A. Bowles, Esq. (in the chair), Miss E. Willmott, Rev. Joseph Jacobs, Messrs. P. Rudolph Barr, J. Duncan Pearson, Jan de Graaff, Herbert Smith, E. M. Crosfield, F. Barchard, Christopher Bourne, C. Lemesle Adams, Harold A. Denison, W. W. Fowler, Wm. Poupart, Charles T. Digby, R. W. Wallace, F. Herbert Chapman, W. Goldring, A. D. Hall, C. Scrase Dickens, and Chas. H. Curtis (hon. sec.).

AWARDS.

FIRST-CLASS CERTIFICATES

Tulip Siren.—This is a Cottage Tulip of the retroflexa type, but the flowers open widely, disclosing the white base to the bright pink segments. The flowers on view were all slightly drooping, in consequence, probably, of their long journey; but if they naturally remain erect after

FIG. 142.—*BULBOPHYLLUM FLETCHERIANUM*: A NEW SPECIES FROM NEW GUINEA.

(See *Orchid Awards*, p. 320.)

rosy-mauve flower with purplish tips to the petals and purplish front to the lip.

R. G. THWAITES, Esq., Chessington, Streatham, showed the clear white *Odontoglossum* *Pescatorei* virginale Thwaites' variety, *Cattleya* *Dusseldorfei* Undine and *Laelio-Cattleya* *Pizarro*.

M. M. MERTENS, Ghent, showed *Miltonia* *vexillaria* *Memoria* G. D. Owen and three hybrids from this.

THE CHELSEA SHOW.

The Chairman called attention to the rule relating to entries for plants to go before the Committee at the Chelsea Show. These must be strictly adhered to, unless in the case of foreign exhibits, the owners of which might not know the rule, which runs:—"Single plants, etc., for Certificates may be entered as late as (entries posted) Thursday, May 14, but no plants can under any circumstances be entered on the day of the show."

being cut this will prove to be a valuable decorative variety. (Shown by Messrs. E. H. KRELAGE AND SON, Haarlem.)

T. Grenadier.—The largest of the Cottage Tulips, which holds itself erect, and is exceedingly decorative. The colour is vermilion-scarlet with a sheen of cerise on the outside of the segments. (Shown by Messrs. H. D. PHILLIPS, LTD., Olton.)

GENERAL EXHIBITS.

Messrs. BARR AND SONS, Covent Garden, London, had a representative collection of excellent Tulips. Besides the standard varieties of Darwin, Cottage, Rembrandt, and Old English Tulip, there were several vases of Tulipa species, such as *T. vividiflora* *praecox* and *T. retroflexa*. The chief Darwins were Bacchus, Negro, and Clara Butt. Of the Cottage varieties, Golden Bronze, Jaune d'Œuf, and Moonlight were good.

Among the English Tulips were especially noted Talsman (bybloemen feathered) and Dr. Hutcheon (bizarre feathered). This group of considerably over one hundred varieties was exceedingly interesting, and showed the different types of Tulip in good form. (Gold Medal.)

The exhibit of Mr. W. A. WATTS, St. Asaph, was magnificent. He displayed a large quantity of bloom in masses of rich, clear colour, harmoniously arranged; seldom has a more imposing display of cut blooms been seen in the Hall. So fine was his group that some of the visitors were of the opinion that it was worthy of a higher award, but they overlooked the important fact that relatively few varieties were shown, and that the group was not representative of the different types of Tulip. As a spectacular display, however, it was worthy of the highest praise. The yellow sorts (Moonlight, Bouton d'Or, and T. Gesneriana lutea) were especially prominent, and enhanced the beauty of the group. (Silver-gilt Flora Medal.)

MESSRS. CARTWRIGHT AND GOODWIN, Kidderminster, had many attractive Cottage varieties in their exhibit of Tulips. Grenadier (the variety which received a First-class Certificate), Scarlet Emperor, William Pitt, and Moonlight were excellent. Besides many Darwins of more than average quality, there were vases of T. Gesneriana lutea pallida and T. retroflexa. (Silver Flora Medal.)

MESSRS. R. AND G. CUTHBERT, Southgate, arranged a display of Darwin and other varieties in vases, interspersed with pots of Maidenhair Fern. Chief amongst the Darwin Tulips were Nauticus, Fairy, Bartigon, Clara Butt and Enrope. Of the May-flowering sorts, Fairy Queen, Mrs. Moon, and Louis XIV. were well represented.

MESSRS. R. WALLACE AND Co., Colchester, specialised with Darwin Tulips of mauve shades. Of these, Erguste, Corot and Dream were noticeable. (Silver Flora Medal.)

MESSRS. ALEX. DICKSON AND SONS, Newtownards, Ireland, showed Bamboo stands, lightly filled with such varieties as Dora, Fen Brilliant, Clara Butt, and Flora's Ornament. (Silver Flora Medal.)

MESSRS. JAMES CARTER AND Co., Raynes Park, constructed a spring garden, bounded by trees and shrubs at the back, and in front by a low wall. The chief feature of the garden was the colour-scheme, composed of Tulips such as Clara Butt, Enrope, G. de Cardous and Sieraad van Flora. (Silver Flora Medal.)

MESSRS. SUTTON AND SONS, Reading, arranged, on a broad, velvet-covered stand, a splendid collection of bright and showy Tulips. The central place was occupied by a large group of Clara Butt, and on either side were tall stands of Moonlight, Mr. Farncombe Sanders, and Sieraad van Flora. (Silver-gilt Banksian Medal.)

MESSRS. DOBBIE AND Co., Edinburgh, showed a collection of Tulips, which bore very fine flowers. The massed blooms of Golden Crown, Pride of Haarlem, Inglescombe Pink, and other varieties made a noteworthy display. (Silver-gilt Banksian Medal.)

MESSRS. ROBERT SYDENHAM, LTD., Birmingham, showed May-flowering Tulips. (Silver Banksian Medal.)

MESSRS. HOGG AND ROBERTSON, Dublin, arranged a collection of Irish-grown Tulips, which gave evidence of suitability of soil and skilful cultivation. Yellow Queen, Psyche, and Gipsy Queen were remarkably fine.

Mr. C. BOURNE, Simpson, Bletchley, had a dainty arrangement of cut Tulips in bright colours.

MESSRS. JOHN WATERER, SON, AND CRISP, Liverpool Street Arcade, London, included many Cottage varieties in their exhibit of Tulips. Of these, Ellen Willmott, Acuminata, Orange King and Yellow Queen were attractive.

MESSRS. WM. CUTBUSH AND SON, Highgate, had a long range of Tulips of most of the standard sorts, making a very attractive display. (Silver Banksian Medal.)

MESSRS. R. H. BATH, LTD., Wisbech, and Mr. A. DAWKINS, King's Road, Chelsea, also showed many fine varieties.

Half a dozen classes were arranged by the National Tulip Society, and the exhibits were displayed in an annexe. The competition generally was poor, and the flowers of Darwin and Cottage Tulips were inferior to those in the Hall.

In every class five blooms of each variety were shown.

Darwin Tulips, twelve varieties.—Mr. C. BOURNE, Simpson, Bletchley, was placed 1st in this class. He showed fresh blooms of good size and form of such varieties as Leonardo da Vinci, Louise de la Vallière, Velvet King, and Mr. Farncombe Sanders. The best blooms in the 2nd prize collection of the Rev. Canon FOWLER, Earley, Reading, were of Isis, Duke of Westminster and Anthony Roozen. Mr. W. O'SULLIVAN, Streatham, was placed 3rd.

Darwin Tulips, six varieties.—The only exhibitor, Mr. H. J. BARTLETT, Shooters Hill, was awarded the 2nd prize for a moderate collection in which the best varieties were Enrope and King George.

Rembrandt or "Broken" Darwin Tulips, three varieties.—The Rev. Canon FOWLER was the only exhibitor, but his blooms of L'Ingénue and Mr. Farncombe Sanders were very good.

Cottage Tulips, twelve varieties.—Mr. C. BOURNE won the 1st prize with a collection rich in yellows (Moonlight, Avis Kennicott, and Mrs. Keightley); Goudrink and Louis XIV. were also good. The 2nd prize was awarded to the Rev. Canon FOWLER, who had attractive blooms of Jaune d'Oeuf, Apricot, and Dom Pedro.

Cottage Tulips, selfs or breeders, six varieties.—The 1st prize was awarded to Mr. O'SULLIVAN, in whose exhibit the best blooms were of Scarlet Emperor, Turenne, and John Ruskin. Mr. A. D. HALL was 2nd; he showed a good Rose seedling named Gloriana.

Cottage Tulips, variegated or broken, six varieties.—The flowers in Mr. A. D. HALL'S 1st prize collection were the best formed; those of the other exhibitors were generally too long in the petals. His varieties were Sam Barlow, Masterpiece, George Edward, Stockport, Sir Joseph Paxton, and Mrs. Collier. 2nd, Rev. Canon FOWLER; 3rd, Mr. H. J. BARTLETT.

Fruit and Vegetable Committee.

Present: Jas. Cheal, Esq. (in the chair), F. Perkins, W. Bates, J. Willard, Wm. J. Jefferies, Edwin Beckett, Horace J. Wright, H. Somers Rivers, A. Grubb, J. Jaques and C. G. A. Nix.

Mrs. E. H. DENNISON, Little Gaddesden, Berkhamstead (gr. Mr. A. G. Gentle), showed large, well-kept bulbs of Ailsa Craig Onions.

AWARD OF MERIT.

Apple Sandlin Duchess.—This late variety is heavily flushed with red on a yellow ground, has a short, thick stalk, and small, shallow eye. It is of medium size, round in shape, and possesses excellent qualities, both for dessert and cooking. The fruits were from an old tree, which will be inspected by members of the committee before the award is made absolute. Shown by Mr. W. CRUMP, Madresfield Court Gardens.

Scientific Committee.

APRIL 21, 1914.—**Present:** Mr. E. A. Bowles, M.A. (in the chair), Dr. A. B. Rendle, Messrs. W. E. Ledger, J. Fraser, C. E. Shea, R. H. Pearson, J. T. Bennett-Poë, W. Fawcett, A. Worsley, W. C. Worsdell, W. Hales, J. Hudson, and F. J. Chittenden (hon. sec.).

Salix showed carpellody of stamens.—Mr. W. C. WORSDELL reported as follows on the curious *Salix cinerea* (not *S. Caprea*, as was at first thought), sent from Bognor by W. B. FLETCHER, Esq., to the last meeting:—

"On a male plant some catkins were normal; most of them had all the flowers female, due to transformation of the two stamens into two carpels, which were quite separate, long-stalked, and contained rudimentary ovules. In a minority of catkins every flower contained two structures transitional between carpels and stamens; each exhibited a terminal stigma, and bore 2-4 pollen-sacs, which contained pollen. The ovuliferous part of the capel is homologous with the anther of the stamen, and the stalk of the carpel with the filament of the stamen."

Mr. FLETCHER also sent *Salix alba vitellina*, with aberrant catkins, upon which Mr. WORSDELL reported:—

"An apparently male plant originally. The catkins contain for the most part normally-constructed male and female flowers intermingled throughout. Here and there was a flower consisting of two organs transitional between carpels and stamens. In one such flower observed, one

of the stamens had become completely transformed into a sessile carpel, while the other was normal save for the presence of a stigma topping the anther!"

Grapes sporting.—Mr. J. HUDSON exhibited a bunch of Grapes said to be of the variety "Hemnapoot," from the Cape, and sent to him by Mr. Lees, of Watford, with two green berries about twice the size of the normal purple ones at the shoulder of the bunch.

Tasmanian Orchid.—Mr. J. W. ODELL showed flowers of the terrestrial Orchid, *Pterostylis curta*, flowering from plants given him by the late Mr. Andrew Kingsmill. Dr. RENDLE kindly verified the name.

Yarrow galls.—Mr. ALEX. MORTIMER, of The Downs, Wimbledon, sent Yarrow (*Achillea millefolium*) with numerous blackish, round galls upon its creeping stems. The sender had not found these in previous years, though the plants had been examined in weeding. The galls were apparently the work of the gall fly, *Trypeta guttularis*.

Virescent Wallflowers.—Mr. CHITTENDEN showed specimens of Wallflowers which had been grown at Wisley, the second generation from the cross of a virescent with a normal Wallflower. In the first generation all the plants were normal, in F_2 segregation into the two parent forms had occurred in the proportion of 101 normal to 42 virescent. There were no intermediates among the plants. The only variation found was in the number of supernumerary carpels—usually six, but sometimes only four. The numbers approximate to the 3 to 1 ratio of Mendel's laws, where the expectation would be 107 to 36.

Abnormal Dendrobium Wardianum.—Mr. CHITTENDEN showed an abnormal flower of *D. Wardianum* from Wisley, which Mr. WORSDELL examined and reported upon as follows:—

"Dimerous flower; two lateral sepals fused into one, which occupies place of labellum, causing the latter to disappear. Lateral petals displaced into a position at right angles to the fore and aft sepals. Column normal."

Gall on Daphne Mezereum.—Mr. W. E. LEDGER showed a shoot of *Daphne Mezereum* with numerous gall-like excrescences at the bases of the lateral shoots. Dr. RENDLE took them for further examination.

Albino seedlings of Crinum Moorei.—Mr. H. W. B. BRADLEY, of Sydney, N.S. Wales, sent two dark and two white seeds of *Crinum Moorei*. He stated that the latter, if sown at once, "will develop ivory-white foliage, but seem to have so little vitality that they die out at the end of the first season. . . . Every year a few albino seeds come without any apparent reason. Generally speaking, all the seeds in a fruit are either albino or normal. Last year, in the same fruit, I had two seeds, one normal, the other albino. Both grew. The normal seed developed a normal plant, with green foliage, which is still alive; the albino seed an albino plant, now dead. This year seedling of *Moorei* has not been at all free, and I have nearly, if not quite, as many albino as normal seeds; last season there were very few albinos."

"In 1912 we had very little rain until March, and we then had a superabundance of rain until August, then no rain to be of any service until after *Crinum Moorei* had finished flowering. . . . The season immediately preceding the flowering in 1913 and 1914 was very similar, and could have had no effect on the matter, as there were very few albinos in 1913 and more than usual in 1914."

Cuscuta on Ramondia.—The manager of the Burton Hardy Plant Nurseries, Christchurch, sent a plant of *Ramondia pyrenaica*, with a *Cuscuta* on its foliage, not identifiable further, however, on account of the absence of flowers.

NORTH OF ENGLAND HORTICULTURAL.

APRIL 29 AND 30.—The spring exhibition of this society was held in the Corn Exchange, Leeds. The exhibits were composed chiefly of hardy plants, many of them of considerable merit. *Narcissus* and Tulips were well shown.

Messrs. R. H. BATH, of Wisbech, showed a large collection of Darwin Tulips, all in good condition and admirably arranged. Clara Butt

was one of the best varieties; the colour is a soft, salmon-pink. Faust, a large, bold flower of maroon-purple, and Flambeau, bright scarlet, were striking and attractive. (Gold Medal.)

Mr. G. W. MILLER, of Wisbech, showed hardy flowers in good condition. An attractive seedling in this exhibit was *Viola cornuta* The Clarkson, a new variety considerably darker than the species, with a distinct Violet scent, to which a 1st Class Diploma was awarded.

Mr. J. MALLENDER, of Bawtry, Yorks, showed *Narcissus* well displayed on a sloping stand. An interesting seedling *Narcissus*, Sybil Forster, to which a 1st Class Diploma was awarded, formed a feature in the display. (Silver-gilt Medal.)

Messrs. ARTINDALE AND SON, of Sheffield, won a large Silver Medal for their display of Alpines and hardy plants. A new pink seedling *Arabis* (*A. Holboellii*) was comprised in this group, to which a 1st Class Diploma was awarded.

A large Silver Medal was awarded to the group shown by Messrs. ROBERT KER AND SONS, of Liverpool, which comprised forced shrubs and greenhouse plants of various kinds. Their *Calceolarias* were well flowered, and *Rhododendron* Pink Pearl carried large heads of delicate blossoms.

Messrs. G. GIBSON AND SONS, Bedale, showed Alpine plants, for which a Silver Medal was awarded.

Mr. J. WOOD, of Boston Spa, showed an interesting collection of Alpines in pans, to which a large Bronze Medal was allotted. Mr. A. AKERS, of Ilkley, was awarded a large Bronze Medal for varieties of florists' *Auriculas*, including the variety Griffith Jones, for which he was awarded a 2nd Class Diploma.

Messrs. MANSELL AND HATCHER, of Rawdon, showed a small collection of Orchids, arranged with their new Fern, *Asparagus Hatcheri* (to which was awarded a 1st Class Diploma). The group included good examples of *Miltonia vexillaria*, *Cattleya Mossiae*, and *Cymbidium Lowianum*, besides a number of other kinds. The group was awarded a Silver Medal.

Mr. T. H. GAUNT, of Farsley, showed a small rock-garden, the stone consisting of water-worn limestone. Saxifrages were grouped about the foundation in bold masses, the effect being very pleasing; varieties of *Aubrietia* were also arranged in clumps. A Silver Medal was awarded to the exhibit.

SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.

MAY 2.—The annual dinner of this society, held at the Café Royal on the 2nd inst., celebrated the twenty-fifth anniversary of the Association. A large and influential company assembled under the presidency of Mr. Harold Beale (of Messrs. James Carter and Co., Raynes Park).

Covers were laid for over 130 guests, and with few exceptions the places were filled. The function was one of the most brilliant in the annals of the society. The tables were beautifully decorated with Tulips and Roses, arranged with the greatest taste by M. Ripard.

The chairman was supported on his left by Sir Geo. Wyatt Truscott, Bart., on his right by M. George Schneider, founder and president of the society. Among other guests were Messrs. J. Mc Kerchar, W. Cutbush, Rudolph Barr, Lelasseur, N. N. Sherwood, Professor Keeble, S. T. Wright, E. A. Bunyard, Guilloud, Ripard, F. Reader, J. F. McLeod, G. J. Ingram, Harman Payne, G. Prickett, F. Gardiner, Reg. Beale, J. Hiehle, senr. and junr., D. Ingamells, T. Stevenson, T. Bevan, W. Howe, R. J. Frogbrook, and Ed. Sherwood.

The toasts of "The King" and "The President of the French Republic" were duly honoured. In proposing the latter toast the chairman referred to his stay in Paris, and his experience elsewhere in France, humorously observing that he had learnt much from that country. He referred to the recent visit of King George to Paris, and said that the warm welcome received by His Majesty had sunk deeply into our hearts.

The next toast was "Success to the French Horticultural Society of London," proposed by the chairman, who opened his speech in excel-

lent French, to the delight of the Frenchmen present. He reminded them of the objects of the society and of its many supporters, among whom he specially mentioned M. Philippe de Vilmorin, Sir Harry Veitch, Mr. N. N. Sherwood, Mr. Harman Payne, Sir Albert Rollit, and Mr. Rudolph Barr, who had each presided over their annual banquet. He was much gratified at the presence and support of Sir Geo. Wyatt Truscott, whose father had been the Chief Magistrate of London. After referring to the early days of the society, and the vast amount of labour expended upon it by their excellent friend M. Schneider, he was glad to say that as he grew older so the work grew lighter. The friendliness now existing between the two great nations was a fact at which they all rejoiced, and this society had done much towards bringing about this excellent result. As there was a long and interesting musical entertainment he would not detain them further. He asked them to drink to the continued prosperity of La Société Française d'Horticulture de Londres, with which toast he coupled the name of their honoured and devoted president, M. Geo. Schneider.

M. Schneider replied. After the kind words of their chairman he would not trouble them with details concerning the society. The suc-

MR. HAROLD BEALE, WHO PRESIDED AT THE ANNUAL DINNER OF THE FRENCH GARDENERS IN LONDON.

cess of the meeting was due entirely to their chairman, whose interest in the society they all appreciated, and to whose generosity they owed an excellent musical programme. He could not refrain from wondering what the early members of the society would have thought twenty-five years ago if they could have seen the present meeting. Little by little the society has made its way until it counts amongst its members the most eminent persons in this country and abroad in the horticultural profession. He was glad to welcome that evening so many of their English friends and supporters, for although they placed young Englishmen in situations abroad, it was to English nurserymen that their thanks were due for receiving young Frenchmen who came here to learn English and improve their knowledge of horticulture. He asked them to drink to the success of English horticulture, to which Sir Harry Veitch would have replied, but as he was too unwell to attend he would ask Mr. N. N. Sherwood to take his place.

At this juncture M. Schneider read telegrams from friends wishing the meeting every success, and from others regretting unavoidable absence. Among the latter were Sir Harry Veitch, Sir Albert Rollit, Mr. Hooper Pearson, and others.

Mr. Sherwood replied, saying he hardly felt qualified to respond to such a toast as English horticulture. He was a seedsman, but he fully appreciated the work the society was doing. He was pleased to do what he could for the society, and hoped the members would pay him a visit during the ensuing year. He proposed the health of the officers of the society.

M. Schneider, on behalf of the society, returned thanks; they would have been pleased to accept the invitation which was given two years ago but for circumstances beyond their control.

M. Sausy responded to Mr. Sherwood's toast of the officers. He was sure that his colleagues were deeply grateful for the help afforded them by the English nurserymen, and also to their past chairman for presiding over their meetings. He asked them to drink the health of the past chairman, coupled with the name of Mr. Harman Payne.

Mr. Payne responded, regretting that he was unexpectedly called upon to supply the place of Sir Albert Rollit.

Sir Geo. Truscott proposed the chairman's health in a very complimentary speech, in which he paid a tribute to the chairman personally and to the eminent firm of which he was a member. He was sure that under such guidance the house of James Carter and Co. would long continue to flourish.

The evening's entertainment was brought to a close by the singing of "Auld lang syne," prior to which M. Legrance, in the name of the young Frenchmen, presented to M. Geo. Schneider a testimonial in recognition of their esteem for his labours on their behalf.

ROYAL CALEDONIAN HORTICULTURAL SPRING SHOW.

APRIL 29 and 30.—The spring show of this society was held in the Waverley Market, Edinburgh, on these dates. The exhibits numbered about 50 in excess of those of last year's spring show, and there was an excellent display of non-competitive exhibits. Favoured by summer-like weather for more than a fortnight, everything seemed in the pink of condition, and taken all round it was generally conceded that, from the point of view of quality, it was one of the best spring exhibitions of recent years, although the competitive exhibits suffered somewhat by the absence of entrants in the leading class—the group of Orchids. The show was opened by the President, and there was a satisfactory attendance of visitors.

GARDENERS' AND AMATEURS' PLANTS.

There were four competitors in the class for four stove or greenhouse plants in flower, and Mr. BALLANTYNE, The Neuk, Peebles (gr. Mr. Allan Smith) was placed 1st, the Earl of HOME, Douglas Castle (gr. Mr. A. McMillan), 2nd, and Sir R. USHER, Bt., Norton, Midlothian (gr. G. McKinna), 3rd. Mr. BALLANTYNE's plants were *Cymbidium Lowianum*, *Anthurium Wardii*, *Rhododendron* var., and *Clivia* var. Sir R. USHER was awarded the 1st prize for six plants in bloom; 2nd, the Earl of HOME; 3rd, J. MCKELVIE, Esq., Halton House, Midlothian (gr. Mr. F. R. Findlay).

Sir R. USHER was the only entrant for four hardy *Rhododendrons*, and he was awarded the 1st prize. This gentleman was also placed 1st for four plants of *Rhododendron* (*Azalea indica*). Col. MORE NISBET, The Drum, Midlothian (gr. Mr. R. Wharrel) was 1st for two specimens, and J. MCKELVIE, Esq., 1st for six hardy *Azaleas*.

Sir A. B. MILNE, Bt., Inveresk Gate, Musselburgh (gr. Mr. R. McAndie) excelled in the class for four Orchids; and the same competitor and R. HINDLE, Esq., Edinburgh (gr. Mr. A. Jeffs) were placed equal 1st for one Orchid.

Mrs. HUTCHESON, Carlowie, Kirkliston (gr. Mr. J. Thom), excelled for four foliage plants, for six foliage plants, for three *Dracaenas*, and three *Codiaeums* (*Croton*). Wm. BARR, Esq., Elie House, Fife (gr. Mr. A. A. Law) won the 1st prize in the class for six table plants.

The Earl of HOME excelled in all the Palm classes, being first for four and six specimens and one plant respectively.

Mrs. HUTCHESON showed the best group of twelve Roses in pots, the best six II P. Roses,

and the best six H.T. Roses. Mrs. DEWAR, Drylaw House, Midlothian (gr. Mr. W. T. Galloway) excelled for two climbing Roses.

Sir R. USHER took 1st place for the following:—Four Ivy-leaved Pelargoniums, four Zonal Pelargoniums, two Deutzias, three Guelder Roses, and three Lilacs. Mrs. HOG, Gogar Burn, Midlothian (gr. Mr. Wm. Brow), excelled in the classes for four show Pelargoniums, six Cinerarias, and six *Cineraria stellata*.

J. McKELVIE, Esq., was awarded the 1st prize for three exotic Ferns and three Adiantums respectively, and Mr. ALEX. BRYSON, Edinburgh, for six dwarf hardy British Ferns.

Mrs. HUTCHESON, Carlowie, was placed 1st for three plants introduced since 1909, with *Dracaena Doucettii* Prince Albert, *Dracaena Warneckii*, and *Adiantum farleyense gloriosum*.

Mrs. HOG excelled for six plants of *Primula obconica* and six distinct species of *Primula*: Sir R. C. MUNRO FERGUSON (gr. Mr. D. McLean) for six *Polyanthus*; Mrs. DEWAR, Drylaw House, for six *Primula Sieboldii*; and Miss WATSON, Edinburgh (gr. Mr. D. Dickson) for six *P. japonica*. Miss BALFOUR-MELVILLE, Pilrig House, Edinburgh, exhibited the best six Alpine *Auriculas*, three Alpine *Auriculas*, six stage *Auriculas*, one white-edge *Auricula*, one grey-edge *Auricula*, and one self *Auricula* respectively, whilst C. W. COWAN, Esq., Dalhousie Castle, Midlothian, excelled for twenty-four and six Alpine *Auriculas* respectively.

CUT FLOWERS.

Mr. L. BRYDON, Innerleithen, was awarded the 1st prize for twelve bunches of *Narcissi*. Mrs. DENNISTOUN, Rosslea, Row (gr. Mr. W. Parlane) excelled for twenty-four Roses, twelve *Roses*, twelve *Maréchal Niel* Roses, twelve *Roses* other than *Gloire de Dijon* and *Maréchal Niel*, and G. D. MACKAY, Esq., Inverlmond, Cramond (gr. Mr. J. A. Sword) for twelve *Gloire de Dijon* Roses.

Lord STRATHEDEN AND CAMPBELL, Hartrigge, Jedburgh (gr. Mr. A. Williams), showed best in the class for three vases of *Souvenir de la Malmaison* Carnations and four vases of other Carnations.

Lord ELPHINSTONE (gr. Mr. D. Kidd) exhibited the best decorated dinner table: 2nd, the Earl of DALHOUSIE, Panmure, Carnoustie (gr. Mr. J. Simpson).

FRUIT AND VEGETABLES.

Lord ELPHINSTONE excelled for Strawberries, and Mrs. HAMILTON-OGILVIE, Biel, East Lothian (gr. Mr. Thos. McPhail), for bottled fruits.

Lord ELPHINSTONE was also placed 1st for a collection of vegetables, arranged in a space 4 feet by 3 feet; 2nd, the Marquis of TWEEDDALE, Yester, East Lothian (gr. Mr. Wm. Hunter).

The competition for garden plants, open only to under-gardeners, resulted as follows:—1st, A. CARD, Milton Abbey, Blandford, Dorsetshire; 2nd, H. G. OLIVER, Royal Botanic Garden, Edinburgh; 3rd, A. MACEY, Chirk Castle, Whitehurst, Wales.

AWARDS.

FIRST-CLASS CERTIFICATE.

Primula Leddy Pilrig (*P. Bulleyana* × *P. Beesiana*), exhibited by Miss BALFOUR-MELVILLE, Edinburgh (gr. Mr. W. Robertson).

AWARDS OF MERIT.

Primula Bon Accord King, *P. Bon Accord Prince*, *P. Bon Accord elegans*, *P. Bon Accord Jack*, exhibited by Messrs. JAMES COCKER AND SONS, Aberdeen.

CULTURAL CERTIFICATE.

Calceolaria Olibranii, exhibited by Sir W. H. HOULDSWORTH, Coodham, Kilmarnock (gr. Mr. McGran).

NON-COMPETITIVE EXHIBITS.

Messrs. SUTTON AND SONS, Reading, showed a large collection of Potatos, with examples of the various Potato diseases. (Gold Medal.)

Messrs. DICKSONS AND Co., Edinburgh, exhibited a fine group of seedling *Amaryllis*, and a large group of *Pink Pearl* and other *Rhododendrons*. (Gold Medal.)

Messrs. DOBBIE AND Co., Edinburgh, showed Rambler Roses, Tulips, Potatos and, for the first time at a spring show in Edinburgh, Sweet Peas. (Gold Medal.)

Mr. DAVID KING, Murrayfield, had an artistic exhibit of spring-flowering subjects, backed by

Palms, which formed a conspicuous object at the end of the hall. (Gold Medal.)

Messrs. CUNNINGHAM, FRASER AND Co., Edinburgh, showed a general collection of Alpines. (Gold Medal.)

Mr. JOHN DOWNIE, Edinburgh, exhibited *Pelargoniums*. (Silver-gilt Medal.)

Messrs. HOGG AND ROBERTSON, Dublin, staged a collection of Tulips and St. Brigid Anemones. (Silver-gilt Medal.)

Mr. H. N. ELLISON, West Bromwich, showed a collection of small Cacti. (Silver-gilt Medal.)

Messrs. MANSELL AND HATCHER, LTD., Rawdon, exhibited a collection of Orchids. (Silver-gilt Medal.)

Messrs. STORRIE AND STORRIE, Glencarse, Perthshire, had a fine collection of seedling *Primulas* and *Polyanthus*. (Silver Medal.)

Messrs. SANDER AND SON, St. Albans, showed Orchids. (Silver Medal.)

Mr. D. McLEOD, Manchester, showed seedling Orchids. (Silver Medal.)

Silver Medals were awarded to Messrs. THYNE AND SON, Dundee, for Alpines; Messrs. PIPERS, London; Messrs. WM. CUTBUSH AND SON, London, for perpetual-flowering Carnations and Alpines; Mr. D. W. THOMSON, Edinburgh, for Tulips; and Messrs. JAS. COCKER AND SONS, Aberdeen, for *Primulas*.

Messrs. JOHN FORBES (HAWICK), LTD., had herbaceous and Alpine plants. (Bronze Medal.)

Mushrooms were shown by the EDINBURGH MUSHROOM COMPANY.

ABNORMAL CARNATIONS: W. S. R. The trouble is due to an excess of vigour. They present the following phenomena: 1, Kind of fasciation or internal branching of the flower, in which the place of the petals seems to be occupied by numbers of very small subsidiary flowers, each of which produces nothing but a great number of petals; 2, Ovary much enlarged, and has assumed the consistence, size, and functions of a calyx for the secondary flower formed by proliferation within the primary one. In the same way the ovary of the secondary flower acts as calyx for the tertiary flower, which, however, is rudimentary. The ovules of the ovary of the primary flowers are rudimentary and few in number, and parietally situated.

CARNATIONS: R. H. The plants are perfectly normal, and the spikes not blind as you suggest. Exercise patience and you should have a good show of flowers.

EVERGREEN FLOWERING SHRUBS FOR A HEDGE: *Nimrod*. As you require an evergreen flowering hedge the choice is restricted to a very few subjects, the two most suitable for your purpose being *Berberis Darwinii* and *Rhododendron ponticum*. The former makes a capital hedge up to 4 feet in height, bearing bright, orange-coloured flowers in April, followed by blue-black berries in August. The leaves are small and neat, and a hedge of this plant can easily be kept in shape by an occasional trimming. If you decide to use this *Berberis* select plants about 2 feet high, which are as large as can be transplanted with safety. It is a somewhat difficult subject to move, and you should insist on the nurseryman supplying one-year transplanted plants. *Rhododendron ponticum* bears lilac-purple flowers about the end of May, but you would not get much bloom from a hedge restricted to 4 feet in height, as the flowers are produced terminally, and in topping the plants you would cut away the flowering wood. This *Rhododendron* may be transplanted at any size.

GOLDEN CURRANT: *Thos. Winkworth*. The *Ribes sanguineum* *Brocklebankii* with yellow young foliage appears to be a very good shrub of its type. We have not seen it before.

NAMES OF PLANTS: *Chas. Palmer*. *Ulmus montana*.—W. S. Plant with largest double white flowers. *Prunus japonica* flore pleno; plant with small double white flowers, *Spiraea prunifolia* flore pleno; evergreen plant, *Choisya*

ternata; tree with white flowers, *Prunus Padus*; bulbs, *Leucoium vernum*; other too shrivelled for identification.—*P. Olearia stellulata*.—W. H. W. 1, *Staphylea pinnata*; 2, *Leycesteria formosa*; 3, *Symphoricarpos racemosus*; 4, *Amelanchier canadensis*; 5, *Pyrus* sp. (send in flower); 6, *Viburnum Opulus*.—T. T. 1, *Berberis Thunbergii*; 2, *Spiraea prunifolia flore pleno*; 3, *Pulmonaria rubra*; 4, *Phlox stellaria lilacina*; 5, *Brodiaea uniflora*; 6, *Saxifraga Wallacei*; 7, S. "Guildford seedling"; 8, S. seedling (unnamed); 9, *Sedum maximum*; 10, *Tiarella cordifolia*; 11, *Saxifraga rotundifolia*; 12, *Arenaria balearica*.—A. H. P. *Corydalis thalictrifolia*.—H. F. Z. 1, *Prunus triloba*; 2, *Cypripedium Calypso*; 3, *Cattleya Schröderae*; 4, *Dendrobium Pierardii*; 5, *Pulmonaria saccharata*; 6, *P. officinalis*; 7, *Tritonia erocata*; 8, *Saxifraga caespitosa* var.; 9, *Saxifraga "Rhei"*.—J. M. S. *Prunus Padus*, Bird Cherry.—J. H. B. *Mackaya bella*.—B. H. *Chrysosplenium oppositifolium*.—*Cestrian*. 1, *Cheiranthus Cheiri flore pleno*; 2, *Gerbera nivea*; 3, *Carex alba*; 4, *Louicera tatarica*.—F. B. *Rhipsalis salicornioides*.—O. R. C. 1, *Masdevallia simula*; 2, *Masdevallia Schröderiana*; 3, *Masdevallia cuniculata*; 4, *Stelis ophroglossoides*; 5, *Oncidium flexuosum*; 6, *Odontoglossum constrictum*.—G. R. H. *Prunus Padus*.—C. S., Surrey. 1, *Cercis Siliquastrum*, Judas Tree; 2, *Pyrus japonica*; 3, *Spiraea confusa*; 4, *Prunus Padus*.—W. R. 1, *Brassavola cordata*; 2, *Thunia alba*; 3, *Cymbidium pendulum*; 4, *Cypripedium vernixium* (*Argus* × *villosum*).—F. J. 1, *Amelanchier canadensis*; 2, *Dielytra eximia*; 3, *Symphytum rubrum*; 4, *Tiarella cordifolia*.

PEACH LEAVES: H. B. The injury to the leaves of the Peach is due to a disease commonly known as "leaf blister" or "leaf curl" (*Exoascus deformans*). In order to prevent attacks the trees should be sheltered from cold winds, preferably by a wall. When an attack has already taken place all diseased leaves should be burned and the shoots cut back beyond the point of infection. Spraying with dilute ammoniacal solution of copper sulphate when the leaf-buds are beginning to expand, and again after a period of three weeks, would prove a safeguard against inoculation by spores borne by the wind.

POTATOS TURNING BLACK: E. T. It is difficult to give a definite reason for your Potatos turning black. In some cases the soil is at fault, but they are sometimes known to become black without any apparent reason. It has, however, been found by experience that when Potatos such as you describe are steamed, instead of boiled, they are a better colour when cooked.

VINES CUT BACK IN JANUARY: S. H. We have known vines succeed, after a loss of one or two seasons, when the old spurs have been cut off close to the rods, but January is too late to perform such an operation, the end of November being a more suitable time. However, the vines may break satisfactorily, and you need not be alarmed about the sap exuding through the bark.

VINE LEAVES SPOTTED: *Bristol*. Besides the spots on the surface of the leaves, the tips of the serratures have a seared appearance. This is called scorching, but is in reality the result of a chill. The mornings up to the last day of April were unusually bright and followed cold, often frosty nights. Vineries under such conditions have required a little ventilation very early, those with an eastern aspect as early as 6 a.m. One with a southern aspect would not need it so soon, but it should be attended to before the temperature rises more than a degree or two, otherwise an abundance of moisture collects on the cold surfaces, and when air is admitted, especially with such a dry atmosphere prevailing outside, this moisture is evaporated too quickly and causes a chill. Black Alicante is one of the first varieties to show the effects of such faulty treatment.

NEW FACTS CONCERNING AMERICAN GOOSEBERRY MILDEW AND ITS CURE.

THE purposes of this article are to describe the results obtained by the author in a series of spraying experiments carried out in 1913, and to draw attention to some fresh facts which have been discovered in the life-history of this mildew.* Both matters are likely to prove of importance to the gardener and fruit-grower. It is satisfactory to note that while, unfortunately, the official legislative measures which were adopted on the importation of this new pest have not prevented its spread far and wide over the country, the attention which has been directed to this mildew is resulting in the acquisition of a better knowledge both of the details of its life-history and of the means of checking its ravages. As will be seen from the facts mentioned below, there is now reason to believe that gardeners, and fruit-growers of a small acreage of Gooseberries, will be able, if attention is paid to certain all-important points, to prevent epidemic outbreaks of the mildew, and save the crop and bushes from serious injury.

In the spraying experiments carried

out with the assistance of Mr. R. G. Hatton, plots comprising several hundred bushes of a number of different varieties, situated on commercial fruit-farms at three centres in Kent (Rodmersham, Mereworth, and Boughton-under-Blean) were sprayed with either the lime-sulphur wash or with a solution of liver of sulphur. The results obtained show clearly the superiority of lime-sulphur over liver of sulphur for preventing the spread of the mildew in its white powdery "summer stage." In one experiment bushes previously quite free from mildew were observed to show a slight trace of it on June 6. The bushes were immediately drenched with the liver of sulphur solution at the strength of two ounces to three gallons of water—clearly the strongest solution advisable, since at this strength the tips of the youngest shoots are turned brown and killed, and the edges of the young leaves are scorched and shrivelled. Another drenching with the same wash was given on June 12—less than a week after; yet an examination on June 23 showed that the disease had not been appreciably checked, many of the shoots and berries being smothered with mildew. Similar results were obtained in other sprayings, while in most cases the use of the lime-sulphur wash greatly checked the spread of the disease.

The lime-sulphur spray at full strength (1.01 sp. gr.) can be used during the early part of the season, April to June, and probably during July in most years, on the varieties named below, without causing any serious injury, even when applied several times successively to the same bushes. The bushes which may be thus treated are:—Whinham's Industry, Rifleman, Warrington, May Duke, Howard's Lancer, Gunner's Seedling, and Cousin's Seedling (Sandwich Yellow), and, when growing in a shaded position, Berry's Early and Lancashire Lad. The varieties named below are liable to be injured if the bushes are sprayed many times successively, or if they are situated in a sunny position:—Berry's Early, Freedom, Lancashire Lad, and Crown Bob, and it is, therefore, advisable to use the half-strength lime-sulphur wash (1.005 sp. gr.) on these varieties, and to avoid spraying late in the season. The varieties Yellow Rough (Golden Drop) and Valentine's Seedling show so great a susceptibility to injury by lime-sulphur and other sulphur-containing fungicides that they cannot be treated.

In early seasons—such as the present season, when the mildew made its appearance so soon as April 6—spraying should be commenced as a general rule in mid-April in all plantations where the disease occurred in the previous season: in other circumstances the first week in May is early enough. The spraying with lime-sulphur should be continued at intervals of about a fortnight to within about a month of the picking of the berries, when the liver-of-sulphur solution or flowers of sulphur should be tried for the purpose of stopping the spread of the mildew to the fruit. By these means it

should be possible to grow a clean crop of berries. After the crop has been gathered a good final spraying with lime-sulphur should be given.

The advantages of the lime-sulphur wash are its cheapness, ease of application, and adhesiveness when dry; a slight disadvantage consists of its sediment marking the berries. The wash is best purchased from firms of repute, who now place on the market lime-sulphur in a concentrated form, with a guaranteed specific gravity of 1.3. Lime-sulphur washes of unknown specific gravity should always be avoided. One gallon of the concentrated wash of 1.3 sp. gr. requires making up with water to 30 gallons in order to obtain the full strength wash of 1.01 sp. gr. suitable for spraying most varieties of Gooseberries; for the half-strength wash of 1.005 sp. gr. one gallon must be made up with water to 60 gallons. The wash is best applied by a knapsack pump, which must be fitted with a nozzle which gives a fine misty spray, such as is supplied with the Vermorel "Eclair" knapsack pump.

The spray, when dry, is so remarkably adherent that even heavy rains do not wash it off; consequently, if there are berries on the bush they become much marked by the whitish sediment. The handling of the berries in the operation of picking removes a good deal of the sediment, and should any appreciable amount still remain, and this be objected to, the berries can be cleaned by a vigorous rinsing in water. It is pointed out—and this is a matter which will need emphasising now that the use of lime-sulphur is becoming so common—that there can be no danger to health in the use of berries with lime-sulphur sediment on them; sulphur is not a poison, and the very small quantities present on berries could not possibly cause any disagreeable effects. As a matter of experiment, I took some berries, which had been specially heavily sprayed with lime-sulphur, with the result that when dry, they were well covered with the whitish sediment, and boiled them with sugar as in ordinary domestic cookery; it was found that no objectionable smell was given off during the cooking, and that the berries when eaten had no objectionable taste or unpleasant after-effects.

While, however, spraying with lime-sulphur is very often successful in keeping the mildew from attacking the berries, I find that in cases where the soil under or round the bushes has become infested with the "winter spores," the berries become badly mildewed in spite of frequent and thorough sprayings. In order to understand how this happens a brief review of the main facts in the life-history of the mildew is necessary. As shown in the coloured illustrations published in *Gard. Chron.*, Dec. 7, 1912, the American Gooseberry mildew passes through two distinct stages in its life-cycle every year: in its "summer stage" it is white and powdery and extremely infectious, the "powder" consisting of myriads of minute "summer spores" (conidia), very light and easily carried by the wind. These spores:

* See *Journal of the Board of Agriculture*, March, 1914.

convey the disease to the leaves, shoots, and berries, and in this stage the disease can be checked by spraying. In the second stage—called the “winter stage,” because, although formed during the summer, it carries on the life of the mildew through the winter—the fungus becomes dense and scurf-like, and produces hundreds of minute blackish fruit-bodies (perithecia), inside each of which is found a little sac (ascus) containing eight “winter spores” (ascospores). No spraying is of any use against this winter stage, because, the walls of the fruit-body being of a corky nature, no chemical is able to penetrate them and reach the “winter spores” inside; consequently, the only way of dealing with the winter stage is to remove and burn it. From personal observations I am able to describe the mode of opening of the perithecia. When moistened with water, a perfectly ripe fruit-body soon cracks open by a slit at the top, and the contained sac begins to swell and protrude through the opening. In about five minutes the sac has swollen enormously, and has become about eight times as large as it was when inside the fruit-body. The wall of the sac becomes thinner and thinner in consequence of the increase in size—just as in the case of a bladder or soap-bubble when blown out—until in a short time it splits and the eight “winter spores” are forcibly ejected into the air to a distance of about 1 inch. Carried about by currents of air, these ascospores reach the leaf-stem or berry and give rise in a few days to fresh patches of mildew in its white, powdery, infectious “summer stage.”

Now, these fruit-bodies are at first firmly attached to the brown patches of “spawn” on the shoots; but as these patches begin to be affected by weather conditions in winter they become loose and drop to the ground. There they remain during the winter, burst open in the spring, and discharge their “winter spores,” which give rise to the fresh spring and early summer outbreaks. This fact has been known for some time, and on this account the removal and burning of all diseased tips of shoots in the early autumn—about October—has been enforced (so far as possible) by the authorities. I have discovered, however, that this soil infestation may take place much earlier. Thus, in August the fruit-bodies formed in the “winter stage” on infested berries have become free; when such a mildewed berry is gently tapped over a piece of white paper hundreds of just visible black “specks” may be observed; these are ripe fruit-bodies containing mature “winter spores.”

In the light of this fresh fact, it is a matter of great practical importance in fighting the mildew not to allow berries with any brown “winter stage” on them to remain on the bush, as there will always be the serious danger of the soil under the bushes becoming heavily infested, in which case spraying in the next season would probably be of little avail in keeping off the mildew from the berries. It was observed that last season this infestation of the soil occurred in August in many plantations in Kent, where late dessert varieties of Gooseberries are grown.

Another fact of equal practical importance is the frequent occurrence of the “winter stage” of the mildew on the leaf of the Gooseberry. In cases where the shoot is severely attacked the young leaves become arrested in growth, and finally covered with the brown “winter stage.” In other cases the leaf itself is not affected in size or shape, and the mildew is confined to the lower part of the leaf-stalk, where a small brown patch of the winter stage is formed. In either case, if such diseased leaves are allowed to fall to the ground they inevitably infest the soil, with the result that next spring the “winter spores” cause fresh outbreaks of mildew. To prevent such soil infestation, “tipping” in August before the leaves fall must be resorted to.

Taking everything into consideration, “tipping” in August or early in September before the leaves have fallen is to be strongly recommended. In some seasons and with bushes of a certain age no further growth of the shoots will take place after this tipping is done; and if all the mildew has been cut off the bush is freed from the parasites, since the disease is always confined to the young wood. If, as will probably occur in some seasons, a little fresh growth is made and this becomes infected with mildew, the grower will still be in a better position, since there will certainly be much less disease to be removed before the “fruit-bodies” fall to the ground.

The following conditions of culture help bushes to withstand attacks of mildew:—(1) An open

FIG. 143.—ONCIDIODA MAURICII: SEPALS AND PETALS DULL PURPLE, FRONT OF LIP PRIMROSE YELLOW

(R.H.S. Award of Merit, May 5, 1914.)

situation. (2) Not too close planting. (3) A natural unforced growth; such is obtained naturally in a good soil or by well-balanced manuring. Excessive nitrogenous manuring—e.g., heavy dressings of organic manures—causes the bushes to produce sappy shoots, which are liable to become virulently attacked by mildew.

In conclusion, it may be pointed out that it is clear that, with the new facts now brought forward, the combat against the American Gooseberry mildew has entered on a fresh stage. If we may conclude, as there seems ground for doing, that the lime-sulphur spray will keep the “summer stage” from doing serious injury, and

that “tipping” in August or September will prevent soil infestation, then all growers of Gooseberries on a small scale should not find it too difficult a task to grow a healthy crop of Gooseberries in spite of the introduction into this country (and doubtless the permanent establishment) of this most serious pest of the Gooseberry. E. S. Salmon.

NEW OR NOTEWORTHY PLANTS.

CYPRIPEDIUM PEREIRAE.

THE subject of this note is a remarkable *Cypripedium*, of which a specimen in formalin and a coloured drawing were sent to me by Mr. J. D. Pereira, Singapore. The plant which he has for sale was obtained on one of the islands near the Laukawi group north of Penang, the home of *Cypripedium niveum*. He suggests that it may be a natural hybrid between *C. niveum* and *C. exul*, although, so far as we know, the latter species has not yet been met with in this region. It certainly has the appearance of being a hybrid of *C. niveum*, with some other species at least allied to, if not actually, *C. exul*. The leaves are linear, rounded, and unequally lobed at the tip, 15 cm. long, green, faintly mottled; the peduncle is 12 cm. or more long, the bract lanceolate, much longer than *C. niveum*, but shorter than *C. exul*, shorter than the ovary. The flower is white, with pink spots on the bases of the upper sepal and the petals. The upper sepal is ovate, pubescent, obtuse, 12-nerved, 3 cm. long, broad-based, and as wide and less orbicular in outline than in *C. niveum*. The lower connate sepals are lanceolate, ovate, obtuse, 3 cm. long and 2.5 cm. wide, shorter than the lip. The petals are oblong, undulate, slightly twisted at the tip, pubescent all over, 4 cm. long and 1.5 cm. across, utterly unlike those of *C. niveum* and its allies. The lip is glabrous, a little longer than the sepals, longer in proportion to its width than in *C. niveum*, with the basal lobes well developed and strongly incurved, as in *C. exul*. The column is thick and hairy, the shield obovate, pubescent, broad, with a short terminal median tooth, but no central base (as there is in *C. exul*), nor is it cordate at the base.

No artificial hybrid of these two species appears to have been made as yet, but a study of the peculiarities of the different organs seems to suggest that Mr. Pereira's theory is correct, and that it is a natural hybrid between the two species. I gather from his letter that only one clump of four plants has been found. It seems to be quite a handsome plant, the nearly pure white flower standing up well on its tall stalk. H. W. Ridley.

ORCHID NOTES AND CLEANINGS.

ONCIDIODA MAURICII.

OUR illustration (fig. 143) represents this interesting cross between *Oncidium tigrinum* and *Cochlioda vulcanica*, for which Monsieur H. Graire, Amiens, received an Award of Merit at the Royal Horticultural Society's meeting on May 5. The sepals and petals are dull purple and the lip primrose yellow. The hybrid is a very interesting one, in that the colouring of the outer segments is like the *Cochlioda*, whilst the lip resembles the *Oncidium*.

CLASSIFICATION OF HYBRID ORCHIDS.

MR. J. GURNEY FOWLER, chairman of the Orchid Committee of the Royal Horticultural Society, submitted at the last meeting of the Orchid Committee, for the consideration of the

Nomenclature Sub-committee a scheme for classifying hybrid Orchids in sections, each under the heading of the species directly or indirectly present in the hybrids.

From notes supplied by the chairman the honorary secretary had ready pictures of thirteen sets of hybrids for comparison. They disclosed interesting facts concerning the variation of plants of the same cross and the resemblance of hybrids of different crosses of the same species.

The subject is under consideration and will be reported on more fully. It has been referred to in these pages on several occasions, and it is well worth following up.

An interesting point in hybrid Orchids is the extreme variation which in some cases appears in the same batch of seedlings. The proposed classification would render the study of these variations interesting and instructive. It is probable that latent features in the so-called species used in making a cross may assert themselves in varying degrees in hybrids.

THREE CANADIAN CYPRIPEDIUMS.

THE glory of many a forest creek and grassy thicket in Canada is the Moccasin flower (*Cypripedium spectabile*), and when first seen in profusion, far from the haunts of man, it evokes a picture of wild flower life that will never fade from memory. The illustration in fig. 144 depicts the purplish form in rich luxuriance in a swampy retreat in Ontario. I shall not mention the exact spot for a reason that all botanists will appreciate. There are two forms, the purplish and the pink, which differ from one another in the matter of environment, the latter seeking rather drier lands in grassy places on the fringe of wood and forest; but the surroundings only accentuate the fresh beauty of the flowers, which are borne on strong, leafy stems about eighteen inches or two feet high. Sometimes three or four flowers appear on each stem. It is unnecessary to describe this beautiful Lady's Slipper, but when found wild in such rich profusion as here depicted, some general reference to it may be opportune.

C. pubescens, a *Cypripedium* of mountain heights, is found under conditions dissimilar from those that surround *C. spectabile*. Near the sun-baked forests this species flowers abundantly, and in the wild plants the colouring is purer and more fascinating than in those under cultivation. The stem, as hardy plant enthusiasts are aware, is strong and sheathed with light green foliage, the flowers sometimes solitary, sometimes three in number, the lip with ruby-red stripes and spots on a golden-yellow ground, and the sepals and petals twisted and coloured into shades of fawn. It is a lovely *Cypripedium* at all times, but in the cool light of its Canadian home seems to have a most alluring beauty.

C. parviflorum enjoys a similar environment to *C. spectabile*—marshy meadows and swampy woods, and there the graceful plant is seen in its wildest beauty. During the day a sweet scent comes from the flowers. *E. T. Cook, Toronto, Canada.*

FUCHSIAS FOR SUMMER BEDDING.

THERE is a greater tendency to employ taller growing plants for summer bedding than was at one time the case. This is perhaps the reason that Fuchsias are now used for this purpose more than ever, for large examples, whether in a bed by themselves or grouped with other subjects, are very satisfactory. Tall, well furnished specimens sunk in the turf, such as may be seen in Regent's Park during the season, are also very effective. To be seen at their best these should be placed at such a distance from

each other that each plant may be distinctly seen, and yet near enough to form one harmonious whole. When associated with other subjects Fuchsias are shown to considerable advantage if thinly disposed over some low-growing plants. In this way the graceful manner in which their pendulous blossoms are borne can be well seen. One advantage that Fuchsias possess over some other bedding plants is that a wet summer, such as we sometimes experience, does not affect them as it does many others; indeed, it suits them better than a hot and dry season. This is to be accounted for by the fact that in the Andean region of South America—the home of the species of Fuchsia—there is a good deal of atmospheric moisture. Many of the newer varieties of Fuchsia are selected by reason of the large size of the blossoms, but this is a feature which detracts greatly from their value for outdoor work. These large flowers are heavy, and much fewer in number than the smaller ones, so that they are liable to break off in strong winds, and each flower leaves a

makes a delightful dot plant. The truly hardy varieties must on no account be passed over. Of them the old varieties *Corallina*, *globosa*, *gracilis* and *Riccartonii* are hardier than some of the newer kinds that have been distributed under this head. These hardy Fuchsias are excellent for a variety of purposes; they are effective in the hardy flower border, in the foreground of shrubberies, and in beds on lawns. *W. T.*

THE CULTIVATION OF RHUBARB FOR MEDICINAL PURPOSES.

THE cultivation of medicinal plants has recently attracted public attention, both in this country and abroad, especially in the United States, Germany and Austria, each country being desirous of producing as far as possible the amount required for home consumption. The cultivation of Rhubarb for its roots has hitherto

FIG. 144.—CYPRIPEDIUM SPECTABILE GROWING WILD IN THE NEIGHBOURHOOD OF TORONTO, CANADA.

vacant space. This accounts for the fact that so many of the older kinds are very generally employed. Some of the best varieties for the purpose are, of the light-flowered section: Amy Lye, Lady Heytesbury, Mrs. Marshall, Idra and Rose of Castile. Of dark flowers: Abel Carrière, Charming, Marinka, Scarcity, Wave of Life, and Valiant. With white corollas: Flocon de Neige and Cadmus. All of the above have single flowers. A few of the best doubles for the purpose are, dark: Auguste Hardy, Comte Léon Tolstoi, Avalanche, La France, and Phenomenal. With white corollas: Duchess of Edinburgh, Madame Jules Chrétien, Molesworth, and Mrs. E. G. Hill. Madame Cornillon, the oldest and most popular of all, has semi-double blossoms. Two dwarf-growing kinds, much used as an undergrowth to the taller ones, are Alice Hoffmann, with a white corolla, and Mrs. Ida Noack, dark coloured. The tinted-leaved kinds, which are often pegged down as an edging, include Cloth of Gold, Meteor, and Regalia; while the tri-colour-leaved Sunray is very pretty, a remark that also applies to *F. gracilis variegata*, which

been confined chiefly to England, France and Austria.

Medicinal Rhubarb has been cultivated at Banbury since 1777, when an apothecary named Hayward won a silver medal from the Society of Arts, and in 1794 a gold medal, for the excellent Rhubarb root that he produced. The species then cultivated was *Rheum Rhaponticum*, although in 1877 most of the plants under cultivation appear to have been hybrids between *R. undulatum* and *R. Rhaponticum*. There were also other growers in Somersetshire, Yorkshire and Middlesex who cultivated *Rheum palmatum*, and to whom medals were also awarded in 1783-1795. In 1873 Mr. Usher, of Bodicott, near Banbury, who was at that time the chief grower in this country of *Rheum Rhaponticum* for the root, undertook, at the instigation of Mr. Daniel Hanbury, the cultivation of *Rheum officinale*, a large and handsome plant then not long introduced from China, and reported to be the source of the Chinese Rhubarb root. At the present date these two species, as well as a little *Rheum palmatum* var. *taughtonii*, are the species cultivated in this country, formerly near

Amphill, in Bedfordshire, but now at Long Melford, in Suffolk, by Messrs. Stafford Allen and Sons. Neither of these possess the exact characters of the best Chinese Rhubarb, nor can they entirely replace it. In France the cultivation commenced in the latter half of the eighteenth century, and the species grown were *R. Rhaponticum*, *R. compactum*, *R. undulatum* and *R. palmatum*, L. In Hungary and Austria *R. Rhaponticum* is the species used, and in Silesia *R. Emodi*. At one time *R. undulatum* was cultivated in Southern Siberia by orders of the Russian Government, but the industry was not long continued.

The root of *R. Rhaponticum* is considered to be less active than the true Chinese Rhubarb, but it yields a powder of a much brighter yellow colour, and on this account is preferred by those who buy cheap drugs. That of *R. officinale* is asserted by those who have tried it to be quite equal in efficacy to the Chinese root.

R. officinale produces roots larger than those of *R. Rhaponticum*, quite equal in size to the finest

field, except in the case of *Rheum officinale*, the inflorescence of which has hitherto been allowed to remain.

The leaf-stalks are never gathered for food because doing so lessens the size and quality of the root. In about eight or nine years the soil becomes exhausted and rotation of crops is necessary; the Rhubarb is planted out in fresh ground, the young plants being set out about 5 feet apart. The root is collected when the plants are four years old, but it improves in quality and size up to nine or ten years of age. Plants of different ages are cultivated in separate fields, so as to ensure a succession of harvests each year.

Plants four years old yield $1\frac{1}{2}$ to 2 tons of dried root per acre, but full-grown plants at ten years old will yield about 5 tons per acre.

The roots are dug up in July, or, if the weather be fine, at any time up to October, and for the first fortnight are exposed to a current of air in wicker baskets in a covered shed, and are then removed to a drying-room, where they

was always sound, having been examined at Kiachta by agents of the Russian Government, and the inferior pieces rejected; but this quality of Rhubarb has not been imported into this country since 1863. Occasionally pieces of Chinese Rhubarb are found brown and rotten at the core, through too quick drying, although the outer surface may be quite sound; and it was to ascertain if the pieces were sound at the core, that the Russians always enlarged the holes made by the Chinese to insert string for hanging the roots up to dry. For the same reason, at the drug sales in this country a number of pieces in each chest of Chinese Rhubarb are chopped transversely, so as to show if they are sound internally.

There is no doubt that the Chinese cultivate different species of Rhubarb in different provinces on the borders of Thibet. *Rheum officinale* is said to be used in Szechuan and *R. palmatum* var. *tanghusicum* in the neighbourhood of Tangut. *Rheum Collinianum* is also stated to yield some of the root, but the species

FIG. 145.—RHEUM OFFICINALE IN FLOWER: CULTIVATED BY MESSRS. STAFFORD ALLEN AND SONS, LONG MELFORD, SUFFOLK.

Chinese Rhubarb, but does not give such a bright yellow powder as *R. Rhaponticum*. It has not hitherto been so carefully dried and does not present so good an appearance as the Chinese root, and has therefore not been able to compete with it.

The successful cultivation of medicinal Rhubarb depends upon a well-drained, but not dry, soil containing a sufficiency of lime. At Bodicott the soil is a rich, red, friable loam, but in spots where the soil remains damp the root is apt to decay internally and ultimately to disappear.

The plant is always propagated from off-sets or lateral shoots. The large central root is more correctly a root-stock, the upper portion having the characteristics of a stem and producing lateral buds which, when the plants are about four years old, are of sufficient size to be detached and made to form new plants. This is done partly because time is saved, and also for the reason that after a few years' cultivation and the cutting off of the inflorescence, so as to prevent the root becoming exhausted, the plant ceases to flower or produce seed, so that it is quite exceptional to see many flower-stalks in a

field, except in the case of *Rheum officinale*, the inflorescence of which has hitherto been allowed to remain.

The central root-stock is either divided transversely or longitudinally, according to size, the longitudinal sections being known as "flats" and the transverse sections as "rounds." The large pieces find a principal market in the United States.

The lateral or true roots are cut transversely only and are known as "small rounds," and are usually supplied in this country when English Rhubarb is asked for; the tapering ends, about the size of a large forefinger, are sold as "stick Rhubarb," and, being cheaper, are chiefly used by herbalists. The pieces, when dried, are trimmed so as to give them a better appearance, and the trimmings ground into powdered Rhubarb. In some cases the larger pieces are bored with a rat's-tail file to imitate the holes which are found in the finest Chinese Rhubarb. This used to come through Russia, and every piece of it

that yields the best Shensi Rhubarb has not yet been identified.

The species used in China appear, however, mostly to belong to plants with more or less palmately-divided leaves. The elegant network of white lines that characterises the Shensi Rhubarb root is well shown in Goebel and Kunze's work on *Materia Medica*, part II., tab. 1, figs. 2b and 3a. No root that has yet been cultivated in Europe shows this remarkable veining. But so far as the medicinal activity of the root is concerned there is no doubt that the root of *R. officinale* prepared in this country answers every purpose. That it could be dried quite as well as the Chinese Rhubarb by means of the machinery now used for drying Hops in a rapid current of hot air is certain. There is one difference between the English dried root and the Chinese, in that in the latter the bark of the root is removed. This has not yet been done in this country, and it is thus possible to distinguish the two. Attention to this matter would remove the shrunken appearance which also characterises English Rhubarb as distinct from the Chinese drug. *E. M. Holmes.*

NOTES ON FRENCH HORTICULTURE.

TREATMENT OF PLANTS DESTINED FOR FORCING.

THE results of comparative experiments on etherisation and on the "warm bath" treatment of plants, communicated by M. Bullet to the scientific section of the National Society of Horticulture show that the treated plants flower earlier and more freely than untreated plants, and give a larger yield of fruit. The trials were carried out with Strawberries, and extended over two years. In last year's experiments 200 plants, subjected for forty-eight hours to ether vapour, were brought into the forcing-house on December 17. Of these plants, 84 were in flower on January 12, 47 on the 14th, and 19 on the 26th.

Another lot of 200 plants immersed in warm water at a temperature of 35° C. (95° F.) for seven hours and brought into the forcing-house on the same date (December 17), flowered as follows:—52 plants on January 12, 67 on the 14th, and 44 on the 26th. An untreated lot of 100 plants was forced at the same time—commencing on December 17. Of these, 5 plants only were in flower on January 14, and 33 on the 26th. Moreover, of 140 etherised plants which were grown on, 56 were bearing ripening (red) fruits on February 25; of 150 plants which had been immersed in the warm bath 55 had ripening fruits on February 25; whereas of 61 untreated plants none bore ripening fruits on that date. The results show that both processes are efficacious for the Strawberry, and to an approximately equal degree.

The method used for immersing the pot plants is as follows: A small plug of straw or hay is wrapped round the collar of the plant to keep the soil of the pot in place, and the pot, resting on two supports, is inverted, so that all the foliage of the Strawberry is immersed in the warm water.

LIST OF CHRYSANTHEMUM SPORTS.*

The *Journal* of the National Society of Horticulture has published (March, 1914, p. 172) a list of Chrysanthemum sports with notes on the colours and the variety from which the sports have severally arisen. Unfortunately, the list does not give the colour of the sporting varieties. Hence, on those who wish to use the list a certain amount of research is imposed. I have succeeded in 118 cases out of 187 in determining the colour. The results of a comparison between the sporting variety and the sport are as follows:—

1. White or white flushed sports have arisen from red, rose, magenta, blue, violet or mauve; but never from yellow.

2. Yellows, with a yellow or chamois ground, constitute the most numerous sports (44). They have arisen from white, and from various colour-forms, such as rose, magenta, red, orange, etc., but especially from whites (14 cases), and rose-lilacs (10 cases). Yellows appear never to have arisen from plants with violet, lilac or mauve coloured flowers. These latter give only red (in three cases), rose (5), and white (3).

3. Yellows rarely throw coloured sports, and even when they do the colour of the sport is similar, though of different shade from that of the variety which yields it. Thus in three sports from yellows the colour is darker, and in two cases the shade is slightly different—e.g., bronze.

4. Apart from the production of white or rose sports, the colour of the sport is generally darker than that of the variety which produced it. Certain varieties have produced large numbers of sports. For example, *Baronne de Vinols*, a magenta, has thrown no fewer than sixteen named sports of yellow, red, rose, purple, and white colours. Next in sporting proclivity comes *Vivian Morel* with 8 and *Mrs. Ch. Harman Payne* with 6. A. M.

NOTICES OF BOOKS.

HARDY CONIFERAE.*

THIS richly-illustrated compendium of Gymnosperms (Pinaceae, Taxaceae, Gnetaceae) hardy in Central Europe is by far the best and most comprehensive book of its kind yet issued. It is the joint work of a number of specialists, edited by Count Silva Tarouca, and the illustrations, original and reproduced from the best sources, comprise every phase of the plant's life from the seed to the fully-developed tree. The editor himself treats of Conifers in landscape, Camille Schneider of architectural associations, Mr. E. H. Wilson of Chinese Conifers, illustrated by photographs of his own selection, and Mr. A. Rehder of American Conifers, also with original illustrations. The illustrations of external morphology are excellent, and in many instances contain from twenty to thirty figures. There is a chapter on injurious insects and fungi, not illustrated. A very large section of the book is devoted to selections for various purposes, especially in relation to soils, situations, climate, etc. The illustrations of specimen in-

insects that visit Primroses, as recorded in his book on pollination, are not mentioned in the essay on the fertilisation of that flower. Again, but few observers of British butterflies can have seen *Camberwell Beauties* "wrestle on high, like gladiators." It seems strange, too, to find it stated that the gorgeous colours of the underwings of moths "seem to serve no useful purpose." One has but to disturb a Red Underwing in the daytime from a Willow trunk, where its mottled upper wings rendered it almost invisible, to find out how eagerly some swallow or sparrow will hunt the bright red flying insect as it zigzags to and fro over the river. I have often laughed at the perplexity of the bird, and the way it has flown hurriedly round to the further side of the Willow on which the moth at last settled, for immediately it closes its wings, hiding the scarlet underwings, it vanishes from its pursuer's sight. The bird still looks for a scarlet moth, and ignores the triangular patch of mottled grey on the Willow bark.

But throughout the book one can find little pictures in words that recall the traits of living things such as the little V-shaped wave running

FIG. 146.—HOLLY HILL: FLAGSTONE PATH LEADING TO THE ROCKERY.

(See p. 334.)

dividuals are almost exclusively Continental, and new to English readers. W. B. H.

THE SEASONS.†

THE seventy-eight short essays collected in this volume range in subject through most branches of the animal and vegetable kingdoms. A glance at their titles suggests that the proverb about Jack of all trades being master of none should be applicable here; but as one turns from zoology to botany, from birds' eggs to toadstools, from the peak of Snowdon to the levels of the Norfolk Broads, it is to find fresh instances of the accuracy as well as the versatility of the writer's powers of observation. It is true that experts in some of these branches of science may find traces of incomplete knowledge of the literature of their special subject. Thus, Knuth's records of the

rapidly towards the shore and then out again, caused by a perch on the feed; or of the robin. "It is his garden. He sits in it where he will. His man dug it while he watched." Again, "When every blade of grass in this lane holds a dewdrop none holds them half so prettily as the half-closed blossoms of the Wood Sorrel."

Somehow the tone of the essays has an undercurrent of sadness, and a realisation of the fleeting nature of the year's pageant pervades most of the records of its joys. The writer has rather an elderly way of looking at things, perhaps explained by a note in the preface that the book embodies the impressions of a City-born man now and then renewing former pleasures among the birds and flowers. It is full, however, of quiet charm, and should help many to seek or recall the pleasures of country walks, the main objective of which is to learn what is going on through the roll of the seasons. Most of the twelve colour plates are landscapes, reproduced from water colours, and pleasantly soft in colouring; but two plates of butterflies and one of birds' eggs, with many varieties shown on each, look rather as though they had strayed from text-books for the young. E. A. B.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

SUMMER-FLOWERING CYPRIPEDIUMS.—*Cypripedium barbatum*, *C. Curtisii*, *C. callosum*, *C. ciliolare*, *C. Lawrenceanum* and their derivatives are on the point of flowering. In the majority of cases the blooms are exceedingly durable, remaining for a long time in a good condition, but the spikes should be removed after the blooms have been expanded for a reasonable time. The albino or green forms of the coloured species are the most liable to suffer exhaustion from this cause, as in the majority of cases they are less vigorous in constitution. The potting of these plants is best done either when new growth develops or just at the time when growth is completing and before there are any signs of flowers. The plants are all shallow rooting and do not require so much potting compost as those of the winter-flowering section. The pots should be filled to about one-half their depth with clean, broken crocks. The compost suitable for most of the tessellate-leaved kinds consists of two parts fibrous peat to one of finely-chopped Sphagnum-moss, with sufficient sand and broken crocks added to render the compost porous. Almost all these *Cypripediums* make continuous growth on a single rhizome. Back growths are rarely produced, and as living roots are rarely attached to them, these growths gain sustenance from the front portion of the plant. It is a good plan to examine the plants a few weeks before potting, and to sever the rhizome. This will induce the old growths to produce new breaks, and the stock may thus be increased or the specimen made larger. *Cypripedium niveum* is one of the most admired among the summer-flowering varieties. The plants grow best in a situation of about 2 feet from the roof-glass, in a structure where the normal temperature ranges from 65° to 70° throughout the year. They are potted in a compost of turfy loam mixed with plenty of lime rubble. The drainage should consist of old lime broken into small pieces. Very little potting compost is necessary, as the roots mat together near the surface. The compost is made moderately firm when the plants are repotted. It is not desirable to disturb the plants for repotting unless the compost is in an advanced state of decomposition or the drainage becomes deficient. During the active growing season water is given by dipping the plants. Care must be taken to prevent the water from reaching above the base of the growth. In the winter season they require no more root moisture than is sufficient to keep the foliage in a plump state.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

SPRING BEDDING.—It is time to consider the clearing of the beds in the formal garden, with their spring occupants, and a beginning must be made with those of which the beauty shows signs of vanishing. Polyanthus, Aubrietias, and Daisies used as carpet plants should be pulled to pieces, varieties selected to colour, and replanted in the reserve garden for next spring's supplies. Wallflowers, Forget-me-nots (*Myosotis*) and *Alyssum saxatile* are best grown annually from seeds, a suitable place being the frames which are at present sheltering the summer bedders. Here they may be shaded and watered during their infancy. Always sow thinly and the plants will become hardier than those from thick, crowded sowings. Hyacinths, Tulips and other bulbs may now be taken up (with roots as intact as possible), labelled and laid in a sunny position in the reserve garden to ripen. Give one watering and Nature will do the remainder. In June or July the bulbs should be taken up and sorted into sizes, and

the largest bulbs placed in bags in a cool store room, in readiness for woodland or copse planting next autumn. It is very seldom that bulbs, however well treated after being removed from spring beds, can be depended upon for a second year's results, and new bulbs can be purchased in large quantities at fairly cheap rates.

CLIMBERS.—Clematis and other climbers should have frequent attention as to training. Give all possible room for extension to the *C. montana* section before the plants become entwined in their young growths. Jasmynes, Wistarias, *Solanums* and *Ceanothus* will require constant attention.

BEDDING OUT.—It will now be safe to bed out Pentstemons, Carnations, *Lebelia cardinalis*, Marguerites, *Alyssums*, *Geraniums*, *Salvias*, *Calceolarias* (*C. anplexicaulis* excepted, being somewhat tender), and Tree Carnations, especially if the plants are properly hardened off already by full exposure to the atmosphere. Everyone should try a few beds or groups of Tree Carnations, struck and grown specially for bedding out. This section will probably in course of time supersede the old border varieties by reason of its long continued period of flowering. On the other hand the border varieties grown in pots under the usual Tree Carnation treatment are superior to those grown under border treatment.

HELENIUM PUMILUM.—Where yellow *Calceolarias* will not grow this plant makes a really good substitute, and keeps up a long summer succession of bright yellow flowers. It may be divided in the autumn and grown in the reserve garden, but is also successful when divided in the spring, using only the best outside portions of the plant and sheltering them from bright, hot sun and drying winds by the insertion of a few Portugal Laurel or other evergreen branches.

BAMBOOS of all sections should be divided, as a small stock of reserve plants is desirable to replace old plants. Bamboos flourish in light, rich loam, with plenty of leaf-soil or humus. Half a barrowful of well-rotted dung placed deep down in the bottom of the hole before planting is good for the plants. Give established plants liberal annual top-dressings of rotten manure, and in hot weather occasional soakings of manure water.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

VINES.—Vineries in which the Grapes are ripe should be ventilated freely both by night and day, and the bunches examined occasionally for the removal of faulty or decaying berries. Be on the watch for the presence of red spider, for if remedial measures are taken in time much trouble and damage will be saved. If pure, soft water is to be had syringing with this is preferable to the common practice of applying sulphur to the hot-water pipes. The spraying should be done during the evening or in the early morning. If needs be the few leaves above the bunches can be sponged by hand. Maintain the requisite temperature and proper amount of atmospheric moisture in successional houses where the berries are swelling towards maturity. See that the lateral growths are not crowded and attend to the work of stopping, tying, and thinning the shoots of vines in later houses. Examine the borders frequently, and afford water copiously when moisture is needed. Encourage pot vines that are intended to fruit in 11 or 12-inch pots next season to grow vigorously. When the rods have grown 7 or 8 feet long stop them, and aim at a gradual ripening of the wood or the results will be unsatisfactory. Young vines that have been planted recently should be encouraged to grow freely in a moist, brisk atmosphere. Keep the roots regularly supplied with moisture. Allow all lateral growth to develop freely, as the root action will be in relation with the top growths.

MELONS that are nearing the ripening stage need careful management; the ventilation of the house is a matter that calls for good judgment. Carefully preserve the leaves from injury of

any kind, and see that they are exposed fully to the sunlight, for this is an important detail in ensuring good fruit. Successional plants require daily attention in the work of stopping and training the shoots, remembering always to allow the growths plenty of room. Red spider and thrips must be destroyed as soon as their presence is detected; the foliage immediately above or near to the hot-water pipes will be the first to become infested with these pests. Water plants that are growing in frames with great care, and keep up the heat of the bed by renewing the linings occasionally. Should there be any danger of the plants "going off" at the collar, heap fine charcoal around the base of the stems, and do not let the water-can reach this part.

CHERRIES.—With the rapid development of the fruit, careful attention must be paid to the watering of the roots, especially of pot trees. When the stoning stage is passed the night temperature may be increased, provided a little ventilation is given. As soon as the fruit shows signs of colouring cease syringing or the fruits will split. The roots also may receive less water, but not to the degree that will cause the foliage to flag, or the fruit would shrivel.

FIGS.—The fruits of the Brown Turkey variety are ripening fast, therefore the roots should receive less moisture, and syringing should be almost discontinued. The top ventilators should not be closed entirely at any time during the ripening period, but a circulation of warm, dry air permitted both by day and night. An occasional damping of the paths and staging will afford, for the time being, all the moisture necessary.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of Derby,
Knowsley Hall, Lancashire.

CHRYSANTHEMUMS.—The main batch of plants should be shifted into 6-inch pots before growth is checked through the roots being pot-bound. Use a similar compost to that recommended earlier in the season, with the addition of a little bone-meal. Pot firmly and secure each plant to a stake. Stand the plants almost pot thick on an ash bottom previously dusted with soot and spray them daily, keeping the atmosphere rather close for a few days. If the soil about the roots is moist, root-waterings will not be necessary for some days. Dust the points of young shoots with an insecticide as a preventive of green and black fly.

FUCHSIAS.—Plants growing in greenhouse borders with shoots suspended from the rafters should be top-dressed occasionally. Regulate the growths to produce a natural appearance. Specimen plants should be placed in larger pots, the soil to consist of two parts loam, one part rotted manure and a little leaf-mould and sand. Pinch out the points of the shoots to make shapely specimens. Plants raised from cuttings last autumn are ready for transfer to 7-inch pots. Those intended for growing as standards should have the side shoots removed, whilst for pyramids secure the main shoot to a stake and pinch out the points of the side shoots beyond the first pair of leaves.

CLIMBERS.—Such plants as *Allamandas*, *Cissus discolor*, *Dipladenias*, *Gloriosas*, *Stephanotis* and *Hibiscus* must receive close attention as regards tying and thinning out weakly growths. Avoid tying up climbers too stiffly or the natural effect will be lost. A very light shading provided by tiffany could be used during the brightest part of the day and removed shortly after closing the house, according to the strength of the sun. For the next two months the night temperature should be 68° to 70°, rising during the day to 80° and 85° with sun heat. Repot *Justicia*, *Scutellaria Mocciniana*, *Acalypha Sanderiana*, *Clerodendron fallax*, etc., before they become pot-bound.

HARDWOOD PLANTS.—Camellias and Azaleas which have made their shoots should now receive a little ventilation, to prepare them for standing outside at the end of next month to ripen their wood. All growing plants, especially hardwoods, must be regularly stopped. Specimens coming into bloom may have a light

shading. Tie the shoots of Hydrangeas, and feed the plants twice weekly with a little fertiliser. Cut back all shrubs that are out of shape, and keep them rather close afterwards to get good breaks. Repot those that require it, and inure them gradually to outdoor temperature before standing them outside.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

STRAWBERRIES.—There is every prospect of a good Strawberry crop, for there are plenty of strong trusses of bloom which are already well above the foliage. If litter has not already been placed along the rows this should be done at once. But first sprinkle soot and lime around the plants to ward off slugs and other insect pests, and remove any weeds that are present. A good layer of the litter should be used, sufficient to protect the fruits from being splashed with soil during times of rain. Have ready the nets for protecting the berries from birds so that they may be placed in position directly the fruits show signs of colouring. Wire netting 3 feet wide and of a small mesh should be fixed around the outsides of the bed, the fish-netting fastened on to this, and supported over the beds either by wires stretched from posts or long, thin green poles, called "binders." Nets supported in this manner last much longer than when allowed to rest on damp ground, nor is there any need to remove them until the crop is finished. Simply placing the nets flat over the beds is the least satisfactory way, as then the birds usually work through the meshes, and the nets are liable to become torn by being removed on each occasion that fruit is gathered.

EARLY RUNNERS.—Strawberries planted late last season should not be allowed to fruit, but encouraged to develop early runners. The flower-trusses should be picked off directly they appear in order to throw all the energies of the plant into leaf-growth. Keep the surface soil regularly but not deeply hoed, and do not allow the plants to suffer from drought, as this would give a check to growth.

MORELLO CHERRIES.—The trees have blossomed profusely and, given favourable weather for a little longer, they should bear heavy crops. The Morello Cherry should be disbudded in the manner recommended for Peaches and Nectarines. The cultural requirements are simple, and perhaps because of this the trees are often accorded very indifferent treatment. If the work of disbudding and stopping the shoots is neglected in the spring the trees become a dense mass of shoots, and are not only much more difficult to keep free from insect pests, but the fruit has little chance to develop. But do not disbud too severely at first; if there are more shoots than required when the training is done the superfluous ones may be stopped at the third or fourth leaf to form spurs. The finest fruits are produced on young wood trained in each season to take the place of the old fruiting branches. Allow each shoot sufficient space to develop, for sunshine and air should reach all parts of the tree. Watch for the first appearance of aphids, which is usually found directly after the blooming period. Spray with a solution of Quassia and soft soap, or some other insecticide, and afterwards wash the trees thoroughly with clear water with the garden engine. See that Cherry trees on walls do not suffer from want of water at the roots, especially where the walls have glass copings.

THE KITCHEN GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of Haddington, Tynninghame, East Lothian.

BROAD BEANS.—A sowing of this vegetable for late supplies may be made at once. Bank soil against each side of the earlier crop to steady the plants against high winds. Some of the plants may be cut to within one foot of the ground to succeed those left to crop, whilst the tips may be pinched out of a few others to hasten the crop—but only a few, because those unstoppped will quickly catch them up.

TURNIPS.—To have nice sweet roots, break the soil very finely and leave the surface somewhat loose before sowing. We must expect times of dry weather now, and the drills for the seeds should be fairly moistened with soft water an hour or so before sowing. Though thin seeding is important, it is as well to allow some of the seeds to fall on the sides of the drill as well as in the bottom. This as a precaution against the attacks of fly. A few drills may be sown with Swedes for winter eating, allowing these about 18 inches between the rows and 9 inches between the plants in the rows.

PATIENCE (RUMEX MAGELLANICUS).—I presume this old esculent is now grown in very few gardens, though at one time it was a usual dish at Eastertide. It comes into use much earlier than Sorrel, and the flavour is so like that of Sorrel that when served as a cooked vegetable one cannot be distinguished from the other. Make a sowing for supplies next year. The plant is absolutely hardy and to succeed needs only to be thinned out to foot spaces and kept clean.

RAMPION.—This is another vegetable not frequently found in gardens. Those who have acquired a taste for the roots like to have a supply for winter eating, and seeds for the present year must be sown soon. My practice is to make the ground very fine, stretch a line to mark the rows, pat with the back of a spade into the soil, and scatter the tiny seeds very thinly therein. By drawing the back of the spade along the surface the seeds will be covered sufficiently. If the weather be dry subsequent to sowing, mats laid along the rows will be advantageous to an equal germination. Shade of this kind is much to be preferred to repeatedly moistening the ground. Allow the plants a space of 12 by 9 inches.

THE APIARY.

By CHLORIS.

REMOVING HIVES.—Those who are removing hives to a new position must remember that it is essential to stand them quite level, and for this purpose it is best to use a spirit level. See that the ground under and around the hives is free of all weeds, so that it can be kept perfectly clean all the season.

NUCLEUS SWARMING.—This is by far the best method of securing increase, and those who propose to adopt it should begin their preparations at once. By this method we have a fertilised and fully-matured queen raised under the very best conditions; further, a young and vigorous queen causes the workers to work more industriously, so more honey is gathered and stored.

METHOD OF CHOOSING A COLONY FOR NUCLEUS SWARMING. Choose a strong stock headed by a queen that is two summers old, very prolific, and whose offspring have been noted for vigour, hardiness and industry. These are the qualities transmitted by the queen, while the drone influences the disposition. For drones choose an equally good colony, introduce drone comb into the centre of the brood-chamber and resort to stimulative feeding, for a queen always deposits more drone eggs when there is a good supply of food. This careful selection of colonies will perpetuate the best qualities and prevent inbreeding. When drones are hatching freely insert a clean worker comb in the centre of the brood-nest of the first hive being stimulated. In this new comb the queen will lay eggs, and in three days it should be full. The queen at the end of this time must be removed. She may be utilised in another hive, as she will be too valuable to lose. Then remove all combs containing unsealed larvae, and these may be utilised to strengthen weaker colonies. The bees will be compelled to raise queens from the eggs in the centre comb, and we can assist them by enlarging the mouths of the cells along the edge of the comb with a conically-shaped stick which breaks down the side wall and that below. A strip may be cut off the lower part of the comb, and the lower cells of the upper portion enlarged to form queen-cells. In this way we shall secure from 10 to 30 queen-cells raised from eggs, not larvae. The advantage lies in the fact that the

former are copiously fed from the start, and finer queens result. During the first eight or nine days there should be plenty of nectar and pollen coming in, otherwise artificial feeding must be resorted to. Next take three combs from a populous hive, one containing honey and pollen and the other two brood. They may be placed in an ordinary hive and kept separate by a division board. The adhering bees should be included, but care must be taken not to include a queen. As the old bees will return to the old hive shake off bees from two or three other combs, so as to have not less than one quart of bees. On the centre comb carefully secure a queen-cell in the middle; in doing so do not shake the cells or the queen inside may be injured. Cover the frames with a well-fitting quilt, and reduce the entrances to prevent robbing. In a few days the queen will be hatched, afterwards fertilised by selected drones, and a week later laying. After the queen has hatched add a comb of hatching brood, or the whole of the bees may leave with the queen when she leaves for her mating trip, in which case all the work will be lost.

THE "FRENCH" GARDEN.

By PAUL AQUARIUS.

NURSERY BEDS.—The first batch of Celery and the whole of the Tomatoes have been pricked out, and the plants should receive ventilation whenever the conditions are favourable. Frames must be reserved to transplant the Tomatoes a second time in the last week of April, 100 per light instead of 250 as at the first time. This method results in strong, hardy plants, which do not wither when set outside. Endive sown early in March is pricked out on hot-beds. Where only a few hundred plants are grown this may be done in boxes, which are placed on the Melon beds until the seedlings are well established, after which they are transferred in cold frames to be hardened off previous to planting out. Further sowings are made as required in hot-beds. Kidney Beans are becoming an important summer crop in the "French" garden owing to the irregular supply from the market gardeners. The seeds are sown in 60-sized pots, and germinated in cold frames, where they receive ventilation and light waterings as needed. They are also covered at night with mats. The earliest batch of Lettuces for the summer crop is now sown. This is a very profitable crop in such season as last year and 1911. Grown as a catch crop they occupy small space, especially as only batches of a few hundred plants are given at regular intervals. The Cabbage Lettuce Vauxhall Defiance has given great satisfaction; it hearts and travels well. The favourite Cos Lettuce is Paris White.

MANURE BEDS.—All the frames and lights have been transferred to the Melon quarter, and the crops of Carrots, Cauliflowers and Turnips are growing fast. The plants should be watered freely with the hose. Where plenty of room has been allowed the Carrots may be pulled for market, and the bed cleared as the work proceeds.

CLOCHES ON BEDS.—The cloches have been placed over the Cos Lettuces which were set outside them. Shading must be done very carefully. The plants will be ready for market within 8 or 10 days, and, as in the case of the first crop, a bed should be cleared at the same time. See that the growth of Carrots, sown as a catch crop, does not become drawn. In the plots previously occupied by the first batch of Cos Lettuces, Cauliflower are set from the February sowing; this crop follows those planted in the cold beds late in July.

COLD BEDS.—All the "Passion" Lettuces should be disposed of within the next fortnight, when the outside crop will be ready. The beds previously occupied with the variety "Little Gott" are cleared of all frames and lights, and where Cauliflowers only are grown the ground should be hoed and a good layer of short manure spread over as a mulch. Carrot sown as an inter-crop should be weeded carefully and watered copiously. Remove the cloches from the Cos Lettuces, and see that the soil is kept moist to promote a quick growth.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.
 Editors and Publisher. — Our correspondents would oblige by delaying in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MAY 19—
 Roy. Hort. Soc. Spring Sh. at Roy. Hospital Gardens, Chelsea (3 days).
 WEDNESDAY, MAY 20—
 Roy. Nat. Tulip Soc. Sh. at Roy. Hospital Gardens, Chelsea (2 days).
 THURSDAY, MAY 21—
 B.G.A. (Watford branch). Address by Mr. Cyril Harding.
 FRIDAY, MAY 22—
 Royal Botanic Soc. Lecture by Professor W. B. Tomlinson.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 53.9°.

ACTUAL TEMPERATURES:—
 LONDON, Wednesday, May 13 (6 p.m.). Max. 55°. Min. 44°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, May 14 (10 a.m.): Bar. 29.8; Temp. 65°. Weather—Bright Sunshine.

PROVINCES, Wednesday, May 13: Max. 57°, Aberdeen; Min. 52°, Yarmouth.

SALES FOR THE ENSUING WEEK.

MONDAY—
 70,000 Bedding Plants, at 158, Ravenscroft Road, Beckenham, by Protheroe and Morris, at 12.
 WEDNESDAY—
 Lilioms and other Hardy Bulbs at 12; Palms and Plants, Tree Ferns, etc., at 5. By Protheroe and Morris, 67 and 68, Cheapside, E.C.
 Orchids, by order of Messrs. Sander and Sons, and Mrs. Cookson. By Protheroe and Morris, at 1.
 THURSDAY AND FRIDAY—
 Greenhouse and other Plants, at The Nurseries, Feltham, Middlesex, by order of Messrs. J. Veitch and Sons, Ltd., by Protheroe and Morris, at 12.
 THURSDAY—
 Orchids, by order of M. Jules Hye de Crom, Ghent; also Seedling Orchids, at 67 and 68, Cheapside, E.C., by Protheroe and Morris.

Manganese as a Fertiliser.

Of recent years much discussion has ranged round the question whether salts of manganese are or are not capable of increasing the yield of crops. Yet, in spite of the discussion and of the very numerous experiments made to test the action of salts of manganese, no certain rule for the guidance of the practical grower has been enunciated. That this is so is due not to shortcomings on the part of investigators, but to the fact that soils differ so much from one another, and are the seat of such complex and contradictory chemical changes, that results obtained with soils of one kind differ absolutely from those obtained when other soils are used. It is probable, indeed, that the experimenters who have been engaged in researches with manganese have been for the most part anxious to obtain results of service to agriculturists, and that this anxiety, so much in evidence at the present time, has defeated the object which they had in view. Nature only answers simple questions, and the simple questions in the present case have not yet—so far as we know—been put to her. It is true that all plants contain manganese, but it cannot be stated with certainty that manganese is an essential constituent of plants. It is also true, as Bertrand was the first to show, that traces of man-

ganese play the part of activators of the oxidation processes of soils and plants; but it cannot be asserted that the acceleration of oxidation processes is necessarily an advantage to the plant. The plant, like the human tiller of the soil, has a labourer's stroke. It must grow at its own rate, and in its growth oxidation and reduction processes alternate and reciprocate. Wherefore it is probable that the curious and capricious effects of manganese will be explained only when investigators begin their investigations in a scientific spirit, and at the beginning ascertaining first by the classic methods whether a plant can do without manganese, as the textbooks' omniscience says it can, and whether the addition of manganese to nutrient solutions of known and varied compositions produces any positive effect on growth. The most recent investigations of the manganese problem, carried out by Messrs. Skinner and Sullivan (*Bull.* 42, U.S. Dept. of Agric.), raise our hopes at the outset, only to dash them at the conclusion. The investigations are as thorough as they can well be. They include experiments with pot-cultures and field-cultures, but, nevertheless, the conclusion to be drawn from them is not decisive. Working with Wheat in pots of unproductive sandy loam, Messrs. Skinner and Sullivan find that manganese salts—chloride, sulphate, nitrate and carbonate—all accelerate growth. The increase is most marked in the case of soils treated with manganese chloride, and almost as great in the soil to which manganese sulphate is added. It is, moreover, considerable, and up to a certain point progressive. The addition of 10, 25, and 50 parts of manganese chloride per million of soil results in an increase of crop weight of 19, 29 and 31 per cent. A further addition of the salt reduces the effect. When, however, similar experiments were conducted with a productive loam the result of adding manganese salts was negligible—the plants grew as well in the normal as in the treated soil. Experiments made with extracts of soils similar to those used in the previous tests show that in the case of Wheat plants grown in the soil solution from the sandy loam the oxidation power of the plant is increased by the addition of manganese salts, and that in the case of Wheat grown in the extract from a productive loam it is not.

Thus it would appear that in a poor soil the addition of small quantities of manganese chloride or sulphate is likely to lead to increased growth, but that on a fertile soil to add manganese salts is waste of time and money. Unfortunately the field trial made by Messrs. Skinner and Sullivan, though it does not necessarily invalidate this conclusion, does not lend it support. Various crops, Wheat, Rye, Corn, Cowpeas and Potatoes, were grown on a silty clay loam, low in organic matter. The physical condition of the soil was rather poor, and the soil was lime-hungry. The result was that in the case of most of the crops the addition of manganese (in the form of sulphate) did not produce any beneficial effect.

The experiments are to be continued,

and the acid state of the soil having been remedied by the application of lime, it may well be that the next few years will tell a different experimental tale. In the meantime the enterprising gardener may, if his soil be very poor, try the effect of giving it a very moderate dose of manganese chloride or sulphate, but if it be of good heart he had better leave it alone so far as manganese manuring is concerned.

Coloured Supplement.—The subject of the Coloured Plate to be published with the next issue is Collette Dahlia "Tuskar."

R.H.S. CHELSEA SHOW.—The Spring Exhibition of the Royal Horticultural Society, which will be held in the grounds attached to the Royal Hospital, Chelsea, on the 19th, 20th, and 21st inst., promises to be even more successful than that of last year. Her Majesty QUEEN ALEXANDRA will visit the show on Tuesday, the 19th inst., an honour of which all horticulturists will be sensible. A few alterations and improvements have been made in the arrangements. The large tent is to be slightly enlarged, and all exhibits are to be grouped on the ground. The area covered by this tent will now be 275 feet by 300 feet, and the dimensions of the other two tents will be 300 feet by 35 feet and 300 feet by 70 feet respectively. In these two tents the exhibits will be staged on tables. New gravel paths are to be laid down between the tents and the outdoor groups, which will much improve the general effect. The Orchids are to be shown in the large tent, space being reserved for them at the north and south ends. The rock gardens will be arranged near the fence at the Embankment end. The whole of the central avenue is being utilised, from one end to the other. The water supply, which is so necessary for keeping the plants in good condition, to say nothing of the requirements of the rock and water gardens, has been well provided for and will be laid on in every part of the grounds. A new second-class refreshment tent has been erected, and also a tent for the exhibitors' assistants, which was much needed. The new plants will be shown all together on one table; their position will be in the second-sized tent. In the sundries tent there will be a special exhibition of paintings of flowers, gardens, and other floral and horticultural subjects.

PROFESSOR BATESON ON DOUBLE FLOWERS.—On the 5th inst. Professor BATESON delivered a lecture on "Double Flowers" at the Royal Institution. He noted the interesting fact that in certain Natural Orders, among which are the Labiatae, the Boraginaceae, and the Gentianaceae, no doubling has occurred. Of the many forms of doubling the commonest is petalody, in which the anthers or other organs are changed into the likeness of petals. Another kind of doubleness is seen in Lobelia, in which each petal is divided. Both these forms occur together in the Paeony. The inheritance of doubling has been much studied in recent years, and it has been shown that in general, doubleness is recessive to singleness. But there are cases in which the heterozygote exhibits a certain degree of doubleness. For instance, in *Campanula persicifolia* the commonly grown double form is a heterozygote, and throws both singles and very full doubles, which are sterile. The Carnation behaves in a somewhat similar manner, for the heterozygote form is double, and throws both singles and the full double which bursts the calyx. The double Stock, which is completely sterile, has been investigated by Miss SAUNDERS. She has found that there are certain strains of singles which throw doubles and singles in the proportion of 9 double, 7 single. By crossing these heterozygous strains with the pure-breeding singles, it was found that the pollen

Photograph by H. N. King.

DUTCH GARDEN AT HOLLY HILL, BUCKINGHAMSHIRE,
THE RESIDENCE OF W. A. JUDD, ESQ.

of the former is all carrying doubleness, whereas the ovules are of two kinds, some carrying doubleness and others singleness. Miss SAUNDERS has also investigated the double *Petunia*, which is sterile on the female side, but bears pollen. The doubles are always obtained by fertilising the singles with pollen from the doubles, and as yet no exception has been found to the rule that singles thus fertilised give both singles and doubles. Professor BATESON then gave a short account of some experiments on the inheritance of doubleness and sex in *Begonia* and in *Tropaeolum*.

HOSPITAL EGG WEEK.—The secretary asks us to remind readers that the collection of new-laid eggs for the hospitals ends on the 19th inst. The eggs should be sent to 154, Fleet Street, London, carefully packed and carriage paid. All boxes used will be returned on request. Supplies of labels for despatching eggs will be sent on application.

PERPETUAL-FLOWERING CARNATION SOCIETY.—The annual dinner of the Perpetual-flowering Carnation Society will be held in the Holborn Restaurant on the 20th inst. (the second day of R.H.S. Chelsea Show), at 6.30 p.m.

NATIONAL DAHLIA SOCIETY.—The National Dahlia Society, with which is incorporated the London Dahlia Union, will hold its annual exhibition on Wednesday and Thursday, September 16 and 17, at the Crystal Palace, Sydenham. The hon. secretary is Mr. J. B. RIDING, Forest Side, Chingford.

NEW PUBLIC GARDEN AT KENSAL TOWN.—The new open space at Kensal Town, presented to the public by Mr. EMSLIE J. HORNIMAN, J.P., will be opened, at 3.30 p.m., on Wednesday, the 20th inst., by the Right Hon. the Viscount PEEL, chairman of the London County Council. The land is about one acre in extent, and has been laid out partly as a children's playground and partly as a "Japanese" garden. A sand pit for children has been provided. The garden, which is to be known as the Emslie Horniman Pleasance, is situated in a densely populated district.

ROYAL GARDENERS' ORPHAN FUND.—The twenty-sixth annual dinner of the friends and supporters of the Royal Gardeners' Orphan Fund will take place at the Hotel Cecil on Thursday, May 21, at 6.30 for 7 p.m. Baron BRUNO SCHRODER will preside. The secretary (Mr. BRIAN WYNNE, 19, Bedford Chambers, Covent Garden, W.C.), will be pleased to receive at once the names of any visitors to the Chelsea show who would like to be present at the dinner.

WINTER SPRAYING WITH NITRATES.—From experiments carried out by Messrs. BALLARD and VOLCK in California (see *Journal of Agricultural Research*, Washington, Vol. I., No. 5), it appears that dormant fruit trees sprayed with nitrate of soda may be caused to blossom precociously. Thus in one experiment 7 12-year-old Apple trees were sprayed on February 2 with nitrate of soda (50 lb.), caustic potash (7 lb.), and water (50 gallons), with the result that the trees blossomed two weeks earlier than did unsprayed similar trees. The effect of the spray appears to have been confined to the flowers, the time of appearance of foliage not having been affected by the spray. Even more remarkable than the hastening of blossoming was the effect of the winter "food" spray on the yield. It is claimed by Messrs. BALLARD and VOLCK that the nitrate-sprayed plants yielded five times as much fruit as was produced by the unsprayed trees. Subsequent experiments show that the forcing effect is less when a weaker strength of nitrate of soda is used, or when the caustic potash—added originally as an insecticide—is omitted. On the other hand, nitrate of soda (1 lb.) and oxalic acid (2.5 lb.) produced a similar effect to that of nitrate of soda and caustic potash. Lime nitrate and lime cyanamid were also used, and each was

effective in producing early flowering. Furthermore, the authors claim that the forcing effect is continued—albeit less markedly—in the second season after the spray has been applied. Various growers in America have put this method of spraying to the test. In one case—of Sweet Cherries—the evidence for precocity of flowering was only partial, and no effect on crop production was noticed. In another experiment Pears were sprayed—on this occasion with nitrate of soda (1 lb. per gallon) mixed with lime sulphur (1.9). The rows thus sprayed came into bloom about a week earlier than those treated with lime-sulphur only. The crops on both plots were full ones. Taking the results as they stand, and examining them critically but in no unfriendly spirit, we cannot say that we are convinced of their conclusiveness. They certainly give ground for believing that the nitrate of soda spray does hasten blossoming time, but the evidence that the yield is increased is not sufficient to justify acceptance of a conclusion of such importance. From the practical point of view we fear that nitrate spraying will not help the commercial fruit-grower, for the dangers attendant upon early flowering are serious. On the other hand, if further experiments confirm the conclusions reached by Messrs. BALLARD and VOLCK, these investigators will deserve the great credit of having put into the hands of horticulturists a method capable of very wide application. Anyone with a taste for experimentation might well test the matter by trying the effect of nitrate spraying on fruits grown under glass. For such an experiment, however, we disclaim in advance all responsibility, since we cannot say whether—as suggested in these pages recently by *Southern Grower*—so strong a solution as 1 lb. per gallon of nitrate of soda might not do harm even to dormant buds.

MAKING CUT FLOWERS LAST.—Useful hints on prolonging the life of cut flowers are given by Mr. S. L. BASTIN in the May number of the *Agricultural Economist and Horticultural Review*. Among these hints is the following:—"For flowers which are really old add a little camphor to boiling water and stand the stalks of the flowers therein." It would appear that flowers almost dead may be revived by this plan. For despatching flowers by rail wooden boxes are better than those of cardboard and tin boxes are best. Tight packing is better than loose packing, and it is best not to sprinkle any water on the flowers in boxes.

LEONARDSLEE AND SUSSEX CHARITIES.—Sir E. LODER will open the gardens at Leonardslee, Horsham, in aid of Sussex charities on Tuesday and Thursday, May 26 and 28, from 2 p.m. to 7 p.m. The fee for entrance will be 1s. We are confident that Sir E. LODER's generous act will attract large numbers of visitors to Leonardslee, the fame of which is world-wide. The gardens are about seven miles from Horsham, which station is reached from London (Victoria) in about an hour. It is no exaggeration to say that no garden scenes in England are more lovely than those presented by Leonardslee. The natural beauties of the site, the skill in cultivation, and the great variety of the plants make upon the visitor to Leonardslee an impression never to be forgotten. At the present time the Rhododendrons—many of them seedlings of Sir EDMUND's raising—are among the most impressively beautiful of the plants in flower. In no garden is the principle *ars est celare artem* more completely carried into effect; each plant grows, not constrained in a bed, but, as it would seem, where it has sprung up naturally, and the juxtaposition of native and exotic trees and shrubs suggests the rich variety of a tropical forest where no two neighbouring trees are alike. Sir EDMUND's interest in his plants is as extensive as the gardens themselves, and visitors who have the fortune to be shown round by Sir EDMUND carry away with them not only memories of loveliness, but a wealth of new

knowledge which renders them not only grateful but also very humble. As is well known, Sir EDMUND LODER is a great naturalist as well as horticulturist, and it is an added delight for the visitor to come upon groups of wallaby, herds of kangaroo, colonies of prairie dogs, all enjoying as much freedom as in their homes. It is by no means our present purpose to describe even in outline the horticultural features of Leonardslee, but only to say enough to make it clear to every lover of wild gardens and beautiful scenes that it is no less in his own interests than in those of the Sussex charities that he should take advantage of Sir EDMUND LODER's kind invitation and make pilgrimage to Leonardslee on May 26 and 28—one day is far too brief, and he who goes on the 26th will undoubtedly want to go again on the 28th. At all events, that was the unanimous verdict of those members of the Council of the R.H.S. who, at the invitation of Sir EDMUND, visited Leonardslee about a week ago.

CHINESE TREES AND SHRUBS.—In his interesting lecture to the members of the Royal Horticultural Society, Mr. BEAN cited figures which demonstrate the wonderful thoroughness of Mr. WILSON's explorations in China. As the results of his three expeditions WILSON has introduced no fewer than 1,500 plants—as seeds or cuttings. Of this number four are those of new genera and 400 are new species. The horticultural value of WILSON's introductions may be gauged by the fact that nearly 100 have already received either a F.C.C. or Award of Merit. Besides enumerating the many plants which have proved valuable acquisitions to our gardens, Mr. BEAN showed how WILSON's botanical explorations have confirmed the remarkable fact of the similarity between the floras of North-east Asian and Atlantic American plants. The facts of such similarity of flora require us to suppose that in pre-glacial times there was a considerable land connection between the continents, and that when plants were driven southward by the gradual onset of lower temperatures, those which took the American route were constrained by the range of the Rocky Mountains to deflect their course: in short, the Rockies acted like the "points" of a railroad, and instead of allowing the plants to run directly southward along the Pacific side, shunted them across to the Atlantic track. As examples of this discontinuity of distribution and of the corresponding species of China and America, Mr. BEAN mentioned the Tulip Tree. Until the discovery of a Chinese species of *Liriodendron* by WILSON the only known member of the genus was the well-known *L. tulipifera* of North America. Other examples of correspondence are *Sassafras*, of which one species, *S. officinale*—the Sassafras tree—is American, and another discovered by WILSON is Chinese: *Symphoricarpos*, with North American species extending so far south as Mexico, and now also with Chinese species. Another scientific aspect of WILSON's work which was dwelt upon by Mr. BEAN is the need for revision of our opinion with respect to the distribution of the Rhododendron. HOOKER's exploration of the Himalayas led to the natural belief that in those mountains the largest numbers of this genus are aggregated. WILSON's collections show, however, that this claim must be withdrawn in favour of that of West and South-west China, which possess an aggregate of about 170 species.

POTATO CROP IN 1913.—The Board of Agriculture has now published the statistics of agricultural productions for the year 1913, and we learn that the estimated average yield per acre of Potatoes was 6.55 tons, exceeding the average of the previous decade by 0.57 ton. This result in England and Wales has been exceeded in only four previous seasons since the produce returns were first collected, and the effect, with the relatively large acreage under Potatoes, was to give the largest total production of England and Wales which has yet been recorded. This total, 2,894,655 tons, was 324,000 tons more than

the decennial average production and about 26,000 tons above the previous largest crop in 1908. Only 13 counties in England and Wales returned lower yields than usual; the best results were in the east and north-east of England, and the least satisfactory in the south-west. On the 76,000 acres planted in Lincoln the yield was four-fifths of a ton above average; in Cambridge (including the Isle of Ely) the crop on 33,000 acres was 1.25 tons above average; on 24,000 acres in the West Riding and 46,000 acres in Lancashire the excess was about three-fifths of a ton, though on 24,000 acres in Cheshire the crop yielded only one-fifth of a ton more than usual.

HOLLY HILL, BUCKINGHAMSHIRE.

(See Fig. 146 and Supplementary Illustration.)

Nor far from the beautiful old parish church of Stoke Poges, immortalised by the poet Gray,

FIG. 147.—RHODODENDRON SEARSIAE: FLOWERS PALE PURPLE.

(See p. 335.)

whose Elegy was written in its churchyard, stands the Buckinghamshire home of Mr. W. A. Judd. Holly Hill boasts of no ancient associations. Seven years ago, when Mr. and Mrs. Judd took possession, it was a small house used as a summer retreat by the previous owners. Of gardening, except an undulating lawn, a few flower beds and a large kitchen garden, there was none. Yet most of southern Buckinghamshire makes good garden land, and this estate is no exception to the rule. Mr. Judd concerned himself with enlarging and modernising the house, whilst Mrs. Judd turned her attention to garden-making, and, as she is possessed of artistic feeling, unflagging energy, and an intuitive knowledge of the right course to adopt, an ordinary uninteresting country residence has been transformed into a very beautiful pleasure. Holly Hill lent itself kindly to this transformation; the estate slopes gently to the south, it is framed with the rich umbrageous foliage which has given the county a world-wide fame, and although the subsoil is heavy clay and retentive of water, with drain-

age and proper cultivation luxuriant growth results. Knowing full well that first impressions are abiding, the entrance received early attention. The carriage-drive is short, but so well have the curves and planting been treated that this is not readily apparent, and there is but little suggestion of the residence until the forecourt is reached. A paved terrace adds dignity to the garden front of the house, and also provides a pleasant promenade, from which, over the tops of the Elms, Beeches, and Oaks which stud the distant valley, a good view of Windsor Castle and its surroundings is obtained. The flower-beds, just wide enough to allow of effective planting, are gay with Wallflowers, which next month are to be replaced by a colour scheme in Antirrhinums, and the house is fast becoming furnished with climbers, which, though growing almost rampantly, ripen so thoroughly in this sunny aspect that flowering is abundant. Several plants of Ceanothus Veitchianus are smothered with filmy blue

Illustration—but now more furnished than when the photograph was taken. Only red and pink Roses are used, and the beds contain distinct varieties. The principal sorts are General McArthur, Hugh Dickson, Richmond, La Tosca, Madame Abel Chatenay, and Caroline Testout. On the pillars the same scheme is observed, and here it is Hfiawatha and Dorothy Perkins, associated with Jackmannii Clematises, which yield a profusion of bloom. In the Dutch garden the Marliac Nymphaeas, around the leaden watersprite, have become strong and vigorous, and stud the surface with rich blooms. A bordering of Sedum spectabile bearing trusses of rose-purple flowers against the dark Yew background provides a charming summer effect, and various lowly herbs relieve the broad paving. On the southern side, in a low and informal rockery (see fig. 146), Campanulas, Alyssums, Aubrietias, Saxifrages, and many other Alpines increase and multiply, and bloom profusely. The companion herbaceous border, where pink Galegas, rosy Pentstemons, and golden Heleniums make a charming feature, is to be replaced by an extension of the rockery and canal, so as to be more in keeping with the paved walk.

When Mr. and Mrs. Judd acquired the property there was a large kitchen garden attached to the residence. This necessary feature was almost as ugly as the kitchen garden at its worst can be. Two long gravel walks divided it into four squares, which were again divided with geometrical precision, making it a severely utilitarian garden, easy to work, and productive of splendid vegetables, but, except to the gourmand, devoid of interest. As is nearly always the case, there were a few redeeming features. At Holly Hill these were a beautiful old standard Cherry, a couple of large, round-headed Stone's Apple trees, and an ancient prostrate Lavender, all of which Mrs. Judd at once decided to cherish and to "work around." The old Lavender bush, weighted down by the growth of ages, and with rugged, twisted, moss-grown stems, looking like a gnarled, prostrate Juniper, is now a fascinating corner piece of the broad flower borders, which stretch down and across the garden. At the present season German Irises, Lupins, Anchusas, Violas, Forget-me-nots, and Alyssum saxatile, with batches of Darwin Tulips flaunting their gorgeous colours just behind large patches of silvery-foliaged Pinks, make a very attractive display, and for a later blossoming there are goodly clumps of Delphiniums, Day Lilies, Veronicas, Erigerons, Canterbury Bells, Sweet Williams, and a host of other summer and autumn flowers, which will continue the display.

There is still a large portion of the ground devoted to kitchen garden crops, and in this sunny, southern slope the edible Peas are already in flower, and rows of strong Sweet Peas promise to be magnificent. On an eastern wall Peaches, Plums, and Apricots are carrying such heavy crops that severe thinning has been necessary. In the glass department the same skilful attention is apparent. The houses of Muscat, Black Hamburg, and Black Alicante Grapes, contain large, well-balanced bunches of splendid appearance. For furnishing the conservatory and for house decoration there are healthy batches of Gloxinias, Gesneras, Achimenes, Begonias, Justicia carnea, Ferns, and Orchids, which will be valuable throughout the summer. The conservatory attached to the residence is gay with Schizanthuses, Stocks, Hydrangeas, Canterbury Bells, Justicia carnea, Primula obconica, and Larkspur Webb's Carmine; whilst from the roof hang rich yellow Maréchal Niel Roses of unusual size and beauty. In this southern aspect shade in summer is essential, and the position of the structure precludes the use of blinds or stippling, but Mr. J. E. Wheeler, the enthusiastic and very capable gardener, overcomes the difficulty by training a Clematis montana over the roof, thus combining beauty with utility. A. C. B.

flowers, and amongst these numerous bees make a drowsy hum. The Heath-like shrub, Fabiana imbricata, which one associates with the western counties, is also in full bloom, and in a sheltered south-west corner Plumbago capensis promises abundant bunches of blossoms in the coming summer and autumn. Sprays of climbing Roses, pushing out from amongst small-leaved Ivies and Clematises, are capped with red-flushed flower buds.

Immediately below the terrace is a spacious tennis-lawn, terminating in a broad herbaceous border, where pillar Roses add their rich beauty to the border display. On the right are shady trees margined with beds of Rhododendrons, in which the white, bell-like flowers of Solomon's Seal show up in contrast with the dark foliage. Amongst the Rhododendrons may be seen stout stems of Liliium candidum and spikes of Foxgloves, for summer and autumn beauty. Away to the left, past a splendid Bay tree and a rockery nook rich in spring flowers, is the Dutch garden and Rosary, which are shown in the Supplementary

RHODODENDRON SEARSIAE.

THERE appear to be a considerable number of small-sized species among the Chinese Rhododendrons, and it is fortunate that cultivators are not blinded to their charms by the magnificence of the giants of the genus, whose progeny are represented by the popular garden sorts. There is room in horticulture for both. One of the best of the Chinese introductions is *R. racemosum*, but it has taken us about twenty years to discover its merits as a hardy free-flowering shrub. When this species first flowered in 1892 it was described as a small Box-like shrub, 6 inches high, with loose terminal heads of pinkish flowers nearly 1 inch across, and not unlike some of the forms of *R. parviflorum*. There are fine bushes of it now 5 feet high, and when in flower they are as showy as the Japanese *R. amoenum*, and of a more pleasing colour. The pretty little *R. nigro-punctatum* has been the delight of not a few gardeners this spring, its clusters of violet-blue flowers being a new feature among Rhododendrons. Patience is required with the small-flowered species; we must wait until they have grown to something like full size before passing judgment upon them as garden plants. Fig. 147 illustrates one of the latest of them to flower, which was exhibited at the R.H.S. meeting on April 21, 1914, by Mr. Reuthe, to whom we are indebted for the specimen. *R. Searsiae* belongs to the *Lepidota* section of the genus, which is characterised by having flowers from terminal buds, corolla campanulate or funnel shaped, medium-sized, and smallish leaves, lepidote or hairy. To this section belong *R. Hanceanum* and *R. ambiguum*, both yellow flowered, and in cultivation; also *R. polylepis* (*Harrovianum*) and *R. concinnum* (*coombense*), which have purple flowers, and are both figured in recent volumes of the *Botanical Magazine* (tabs. 8,509 and 8,280). *R. Searsiae* was named by Wilson in compliment to "Sarah Choate Sears, artist, successful cultivator and lover of flowers." It is described in *Plantae Wilsonianae* as a shrub 2 to 5 metres high, with slender branches, covered when young with brown scales; leaves thin, leathery, lanceolate, margins revolute, 2 to 4 inches long, dark green above, at first scaly, afterwards glabrous, glaucous beneath; petioles purplish; flowers 4 to 8 in terminal umbels, with short pedicels, shallow, campanulate, 5 lobed corolla nearly 2 inches across, white or pale purple; stamens 10, longer than the corolla; style and stigma purple. A native of Western Szechuan, where it grows in thickets at an altitude of 2,500-2,800 metres, it was collected in flower in June, 1908. In the same section, and therefore nearly related to *R. Searsiae*, are *R. Augustinii*, now fairly well known in cultivation, and *R. moupinense*, a figure of which will be found in this volume, p. 155; the latter has small leaves and fragrant white flowers, and is a most promising plant for the rock garden. W. W.

PACHYSANDRA PROCUMBENS.

PACHYSANDRA procumbens (fig. 148) is one of the most interesting and pretty of rare herbaceous plants and is quite novel in character. Its attractiveness is mainly due to the thickened white filaments, though the dark bronzy leaves, which form a fine contrast to the flower spikes, are very handsome. The habit of the plant is well shown in the illustration, which is reproduced from a photograph taken in the Botanic Gardens here, where the plant forms a tuft about 2 feet across. The popular name is the Alleghany Mountain Spurge, but it is a native also of Carolina and Kentucky. There are three other species, *P. terminalis*, a useful diminutive shrub for the rockery, which, in its variegated form, is not infrequently found in botanic

garden greenhouses, and two other comparatively new species, both natives of China, but not known to be in cultivation. The genus belongs to the Buxaceae, and is most nearly allied to *Sarcococca* and *Buxus*, though it differs widely in appearance from both. It has capsular fruit like *Buxus*, but the leaves are alternate instead of opposite, and *Sarcococca* stands alone, because of its baccate fruit. The flowers are monoecious, the pistillate and staminate on the same spike. The sepals are four, the stamens four, opposite the sepals, the filaments thick, and long, exerted.

The present species is of spreading habit, and as the spikes of flowers are borne near the stem bases, the general effect is that of a central flowering area, with a ring of foliage outside. The stems are about 9 inches long, stout and unbranched; the leaves are 2.4 inches long, ovate, oval, or obovate, obtuse or acute at the apex, coarsely dentate, or in some cases entire, narrowed at the base into a petiole, either shorter than the blade or about equal to it; the spikes are one or several in the axils of the lower scales, densely, many-flowered, 2-3 inches long, the greater part of the lengths with stam-

A specimen of *V. Hulkeana*, however, sent by a correspondent showed the young leaves and growing points dry and withered, and the under surfaces of the leaves entirely covered with a dingy white mildew, which on examination proved to be *Peronospora grisea*. It is highly probable that this *Peronospora* will, now it has acquired the power of attacking exotic species, prove a very serious pest to cultivated species of *Veronica*, as there is no reason to doubt its ability to spread to other species of this genus. In *V. Hulkeana* the fungus appears to attack only the young shoots and leaves, which are speedily killed outright, consequently the increase in size of the bush is checked. On the other hand, it is not uncommon to see plants of *V. Chamaedryis* or *V. Beccabunga* having the under surface of almost every leaf covered with a delicate dingy white mildew, yet the plant is not killed, nor, it appears, very much inconvenienced.

This is another illustration of the well-known fact that a fungus on first attacking a new host causes serious injury, whereas it often does but little damage to a host to which it has long been accustomed. In future everyone wishing to grow

FIG. 148.—PACHYSANDRA PROCUMBENS—THE ALLEGHANY MOUNTAIN SPURGE.

inate flowers, the pistillate, with comparatively large fleshy spreading styles, a few only towards the base; the filaments are from a third to nearly half an inch long. The flowers are produced in April and are fragrant. There is a figure in the *Botanical Magazine*, tab. 1964.

The culture of the plant is quite simple. Cuttings would no doubt strike, but most conveniently perhaps it may be divided. It grows in woods, so that some shade is no doubt desirable. It is here fairly in the open, but with the shadow of trees passing over it. *R. Irwin Lynch*, *Botanic Gardens, Cambridge*.

DISEASE OF VERONICAS.

AMONG some plant diseases sent to the *Gardeners' Chronicle* for identification recently was one which possesses considerable interest. The fungus in question, *Peronospora grisea*, de Bary, has hitherto been thought to be strictly confined to various wild species of *Veronica*, being of common occurrence on the leaves of *V. Chamaedryis*, *V. agrestis*, and *V. Beccabunga*, etc.

Veronicas should exercise the precaution of keeping down all weeds belonging to the order *Scrophulariaceae*. *L. Massee*.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE BEAUTY OF FRUIT BLOSSOM.—There are two periods of the season when, to my taste, an old-fashioned garden, with an orchard attached, is more beautiful than at any other time. The first is when Cherries, including Double Cherries, and Pears are in full bloom; and the second, closely following, is when Lilac, Laburnum, Guelder Roses, and Apples are in full beauty, if they are so at the same time, as is the case this season. Plums in full bloom make a charming off-hand sight, but on close observation are not nearly so beautiful as Apples, Cherries, or even Pears. Apple blossom, in my opinion, is pre-eminent, particularly that of varieties which are most pink, such as Lord Derby, Domino, Cox's Orange Pippin, Charles Ross, Benheim Pippin, Mr. Gladstone, Irish Peach, and Allington Pippin.

Beauty of Bath is gorgeous from its thick and large bunches of bloom, but is not deeply tinted, while Worcester Pearmain is the least prettily coloured of any Apple that I grow. The display is most striking in the cases of varieties which naturally grow symmetrically, and blossom on short natural spurs along the branches. *Southern Grower*.

PEACH LEAF CURL OR BLISTER.—I was much interested in Mr. J. Gardener's note on p. 319 of your last issue. I should like to know if Mr. Gardner sprayed the whole of his Peach trees on the outside walls, for if all were treated the test cannot be regarded as conclusive, as alternate trees should have been left unsprayed. Some few years ago the Peach and Nectarine trees on the outside walls here were very badly attacked by "blister" for several successive years. At the time there was advertised a preparation that would check the disease, and I intended ordering some, but forgot to do so until too late to use, and, strange to say, that year there was not a leaf affected, and the three following years the trees were almost immune from curl, and there is very little of the disease this season. I only mention this to show how necessary it is to give fair tests before anything definite as regards a certain cure is claimed, and the only satisfactory way is to spray alternate trees with the Bordeaux mixture and see if these remain free each season after the spraying, and to watch those that are unsprayed to see if the fungus attacks them. If I had bought and used the specific four years ago I should undoubtedly have said that it cured Peach leaf curl or blister. *A. Jefferies, Moor Hall Gardens, Harlow, Essex.*

DAMAGE TO FRUIT BY FROST.—I have seen reports from several parts of the country on serious damage to fruit crops by frost which occurred early in the morning of May 2. The maxima varied from 9° to 15° of frost. The damage to Strawberries, Plums and Pears in most of the districts was serious, one estimate being that three-fourths of the Plums were killed. Gooseberries generally were more or less damaged, and Currants in some places. The extent of damage to Apples is variously reported. In my own district thermometers 4 feet above the ground level have not fallen below freezing point since March. *A Southern Grower.*

SERVANTS OF THE CROWN.—An appeal is being made by the Committee of the Kew Guild on behalf of Mr. Crisp, who for a period extending over 34 years has served both Kew Gardens and the Crown faithfully and well in the capacity of packer. It appears that Mr. Crisp has been compulsorily retired on account of age limit, and it goes without saying that the salary attached to that office precludes the possibility of anything beyond a very meagre sum being set aside for a rainy day or old age. He is granted a gratuity of £47 12s., which in the most careful and economical hands must render the recipient practically penniless in less than a year. Is it not a shame in this the wealthiest country in the world that men should be thrown upon the scrap heap in this heartless fashion after long and faithful service? Had Mr. Crisp served a municipality he would have been comfortably placed for the rest of his days, freed from anxiety as to the wherewithal to keep his body alive and a shelter over his head. A large and ever-increasing number of public bodies, also private concerns, point the way in this matter, and the Government may and should follow the good example set by them. What kind of a chance has Mr. Crisp at the age of 60 to secure employment, and is it reasonable and humane to oblige him to scour the country in search of it? *Walter H. Aggett, Superintendent Public Gardens, Hermondsey, S.E.*

THE LESSER NARCISSUS FLY (EUMERUS LUNULATUS) (see pp. 240, 272, 302, 318).—I fear that your readers are by this time feeling a little bored by this small fly, and inasmuch as both Mr. A. J. Bliss and I agree that very little is at present known about it, while those having the time and special facilities for dealing with its life-history are at work upon the matter, it is difficult to see what practical good can result from a prolonged discussion of your correspon-

dent's particular views upon the subject. He pleads that "our proper attitude should be an open mind." Exactly, and if he will read more carefully my previous letters he will see that this has been my position from the first; in fact, it is put forward in my first letter, but with the suggestion that, from prudential considerations, it would be well "until thoroughly investigated under scientific conditions, to reverse our usual judicial practice and to consider the accused to be guilty until he has been proved innocent." But otherwise I hold no brief for the prosecution, and no one would be more pleased by a verdict of acquittal than I, but that verdict has not yet been given. On the other hand, Mr. Bliss's "open mind" has been evidenced by an open, and persistent, advocacy of the "scavenger" theory, an advocacy which could only tend to put people off their guard, and disastrously so, should, in the end, the verdict be given the other way. To negative this tendency I have naturally pointed out what I have considered, and still consider, the very weak points in Mr. Bliss's case. But surely the time has now arrived when we may consider that the need for precautionary measures is widely recognised, and so a further discussion of what that gentleman's particular views may be would be but waste of time. We can afford to wait the result of the scientific investigations now in progress, although I must confess that I should

FIG. 149.—PERONOSPORA GRISEA.
(See "Disease of Veronicas.")

dearly like to have more of your correspondent's views of what are, and are not, "crude unscientific conclusions." In fact, I must confess to a difficulty in "placing" Mr. Bliss's "more than so-called fact" that the finding of Eumerus larvae in a rotting Iris rhizome proves that the rot came before the larvae. This may be an assumption, as in the case of the Narcissus, and further investigation may show this to be so. This is, of course, a mere suggestion, but as Mr. Bliss presumably did not lift, and examine, his Iris until it was observed to be out of health, and then found both rotten tissue and larvae therein, was it *post hoc* or *propter hoc* in that case, or a jump to a conclusion? But I note with pleasure that Mr. Bliss has brought into the arena our old friend the Merodon, on the question of where it lays its eggs. Poor fly, it must be very pleased, even if only at this late hour, to find that it is not quite left out in the cold, overshadowed by the prestige of its younger and smaller brother. *Charles E. Shea.*

—The discussion between Mr. A. J. Bliss and Mr. Chas. E. Shea is most enjoyable reading, and to those who give attention beneficial results are bound to accrue. Mr. Chas. E. Shea, writing in *The Garden*, April 18, p. 191, says: "Eumerus lunulatus rivals its great brother, the Merodon equestris, in its capacity for destruction. . . . Both eat out the

interior of the bulb, resulting in almost every case in the destruction of the bulb." In his letter to the *Gardeners' Chronicle*, May 2, p. 302, he charges Mr. Bliss with the use of deductive reasoning. Are we to assume that Mr. Shea's statement above is not deductive reasoning? If not, then I would suggest production of proof. A close examination of any bulb troubled like his Glory of Noordwyk ought to furnish evidence. Mr. Shea writes: "It seems to me that where so little is really known about the matter there is a better guide than mere surmise, and that is the guidance furnished by what is called analogy, and in this case, as the Merodon and Eumerus are so closely allied," etc. They certainly are allied in entomological classification, but there the resemblance ceases. They are different in general appearance, in habit, and in their life-cycle, and I am therefore puzzled to know where the analogy comes in. Mr. Bliss has given us some strong arguments respecting Eumerus feeding on decaying matter. It is no argument to say that because the Merodon eats the living tissue that Eumerus does also. To me such deductive reasoning lacks conviction. But we must ever bear in mind that the cleverest reasoner has not all the arguments. *Geo. St. Oz, Doncaster.*

STRANGE HOME OF A PAIR OF OWLS.—A pair of little brown owls have made their home in a remarkable place on one of our farms. They have laid their eggs in the furnace of a portable boiler used for washing beehives, and their larder is well stocked. Of course, the fire has not been lighted recently, but the copper is used every day, and when the owls are at home they do not mind this at all. They find their way in and out of their home by means of the small iron chimney attached to the copper. This species of owl is not indigenous to Great Britain. Lord Lilford brought a pair of them from Spain and kept them in captivity at Lilford Hall, near Thrapston. They thrived, and several years ago he turned them out into the open. Since then they have multiplied, and are now fairly common in the Eastern Counties. The interesting thing about the little brown owl is that it flies by day as well as by night, and there is much difference of opinion as to the amount of harm or good that it does. *Chivers and Sons, Histon, Cambridge.*

TREES AND SHRUBS.

MAGNOLIA KOBUS.

NEVER previously has this tree flowered here with such profusion as at the present time, rivaling even the better-known *M. stellata* in this respect. The flowers have some resemblance to those of the latter species, but are not so spreading, are larger and have fewer petals, six being the usual number. Like those of *M. stellata*, the flowers are easily damaged by cold winds, therefore the tree should be planted in a sheltered position. Specimens are said to attain to a height of 70 or 80 feet in Japan, its native country. The specimen here is only about 14 feet high, but it is growing freely, and, as we are training it to one stem, it bids fair to become a tree of considerable size.

PRUNUS SPINOSA, FL. PL.

THE most noticeable plant in the Bath Botanic Garden recently was a fine specimen of the double Sloe in full flower, demonstrating once again, as it does every year, what a fine tree it is in spring. The flowering of this plant is annually looked forward to by numerous visitors to the garden, and it never disappoints, but year after year creates such a picture as to warrant its inclusion in the most select garden. Our tree is about 20 feet in height and as much across, and was smothered with its tiny, pure-white flowers. Like other plants which flower before the leaves develop, it should have a background of some dark-foliaged evergreen. *J. D. Halliburton, Royal Victoria Park and Botanical Gardens, Bath.*

GRAFT HYBRIDS.

I.—THE RHODODENDRON.

THE occurrence of a graft hybrid Rhododendron is recorded by Messrs. D. Bois and G. T. Grignan in *Revue Horticole* (August 1, 1913). It arose as a result of grafting the variety Madame Linden on a stock of Rhododendron Cunningham's White. A shoot which had been left on the stock just below the graft produced pale rosy-lilac flowers; whereas the flowers of the stock are white, and those of the scion deep rosy-lilac with dark red spots. This form of leaf borne by the anomalous shoot is also distinct, approaching that of the scion.

II.—PEACH ALMOND.

MESSRS. DANIEL and Delpont describe in the journal above cited (September 1, 1913), a graft hybrid between Almond and Peach. A Peach grafted on the Almond bore as its first crop true Peaches, but produced in the next year buds, some of which resembled those of the Almond; others were like Peach buds, and others again were intermediate. Seeds from the graft have produced trees, the foliage of which resembles both that of the scion and stock. The trees have not yet flowered.

III.—BELLADONNA AND TOMATO.

By grafting Tomato on Belladonna, Mr. Daniel (see *Rev. Hort.*, July 16 and August 1, 1913) appears to have obtained decisive evidence that scion may influence stock. He shows that the Tomatos produced by the graft contain an alkaloid allied, chemically and physiologically, to atropine; whereas Tomatos grown normally do not contain this substance.

BRAMBLES FOR WINTER EFFECT.

UNTIL the introduction of *Rubus Giraldianus* the best of the white-stemmed Brambles for winter effect was *R. biflorus*; but the new Chinese introduction surpasses the latter, both in grace and general effect. Mr. W. J. Bean, in describing *R. Giraldianus* in the *Kew Bulletin* (No. 2, 1914), states that it has a fountain-like habit, the stems rising erectly for 5 to 7 feet, and then arching so that the tips reach the ground. They root at the tips, and hence propagation is easy. A white or blue-white waxy bloom covers the stems, and though most vivid in October, remains all the winter. The stems are biennial, reach their full length by the first autumn, and flower in the following spring, and ripen their black fruit in late summer. After fruiting the shoots should be cut out. *R. Giraldianus*, though discovered originally by Giraldi, was introduced into cultivation by Wilson in 1907. K.

SOCIETIES.

ROYAL HORTICULTURAL
Scientific Committee.

MAY 5.—*Present:* Mr. E. A. BOWLES, M.A. (in the chair), Rev. Canon FOWLER, Messrs. J. FRASER, W. C. WORSDELL, J. RAMSBOTTOM, W. HALES, G. WILSON, A. WORSLEY and F. J. CHITTENDEN (hon. sec.).

Pelargonium hybrids.—MR. FRASER continued his remarks upon *Pelargonium* hybrids, dealing with those into whose composition *P. quercifolium* had entered. The complete record of his examination of these forms will be published in the *Journal* of the society later on.

Scale Insect on Furze.—THE REV. W. WILKS exhibited a branch of Furze thickly infested with a cottony white insect looking very much like a scale insect, and probably identical with *Pseudomonas ulmi*, which has previously been recorded as attacking that plant.

Malformed Rose.—MISS COLLIN sent from Surbiton a very curious malformed rose, which Mr. Worsdell took for further investigation.

Beech with curious root growth.—A specimen of Beech came from Mr. P. T. GODSAL, of Iscody Park. The tree had been, it is supposed, struck by lightning, and partly killed, the upper living portions had sent bad roots which had grown down, branching as they went, to the ground, beneath the dead bark. This kind of growth is not infrequent in Willows.

"Fire" in Tulips.—REV. CANON FOWLER said that this season the Tulips in his garden were remarkably free from "fire," though last season they had been badly diseased. MR. CHITTENDEN said that plants in his garden exposed to wind had suffered badly, but in the Tulip trial in the Wisley garden scarcely any was to be seen. There they had been protected by putting branches of Broom between the beds.

Schizanthus malformed.—A *Schizanthus* in which the flowers had apparently been displaced by vegetative shoots was received from Mr. CROSSWELL, of Pichhurst Manor, Hayes, and referred to Mr. Worsdell for further examination.

Uncommon plants.—MESSRS. PERRY exhibited *Iris minuta* with narrow petalled yellowish flowers about an inch across, native of Japan, and *Glaucidium palmatum*, a beautiful Ranunculaceous plant, with divided bracts on the single flowered scapes, and a mauve flower about 2 inches in diameter, with yellow flowers, native of the same country.

HORTICULTURAL CLUB.

LECTURE ON INDIAN GARDEN CRAFT.

MAY 5.—ON the occasion of the usual monthly dinner of the Horticultural Club, at the Hotel Windsor, on Tuesday, May 5, a most interesting lecture on Indian garden craft was delivered by Mrs. PATRICK VILLIERS-STUART. MR. A. WORSLEY presided, and amongst the guests of the club were Her Excellency Lady Hardinge of Penhurst, Lady Margaret Graham, Sir Krishna Gupta, Mirza Ali Baig, Colonel and Mrs. Sykes, Mrs. Fielden, Captain Patrick Villiers-Stuart, and Mr. Allen, editor of the *Pioneer* (India). The lecture was illustrated by a series of very beautiful lantern views in colour. We print below a contribution on the subject of the lecture from the pen of Mrs. VILLIERS-STUART.

THE OPEN-AIR HOUSE.

ACCUSTOMED as we are, under our rainy northern skies, to a sharp distinction between house and garden, Indian garden craft may seem at first more architectural than horticultural, for it springs, not so much from the requirements of flowers and plants, as from the needs of the people who grow them, and live in their gardens. The Indian garden is an open-air house. Its separate pavilions correspond to our several rooms with their various uses. This fact, taken into consideration with the arid climate and the consequent need of irrigation, governs the whole design of these country houses or architectonic gardens.

Water is a vital necessity to cool the dwelling rooms and supply the baths, to fill the big swimming tanks, as well as to moisten the air with "pearl showering" fountains, or charm the

eye with the lovely tranquil reflections of the long canals, that form the cosmic cross on which the old designs are based. The soul of an Eastern garden hides not in the flowers, the grass, the trees, but in the running water that alone makes its other beauties possible.

AN INDIAN COUNTRY HOUSE.

FOR a time I stayed in just such a place, situated far away in the country of the Himalayan foot-hills. It was a huge walled enclosure, partly fortified. First came the great high gateway, which formed the double purpose of entrance hall and quarters for the guard; beyond extended a large flower garden, laid out in parterres, with Marigolds, Cypress trees, and Palms bordering the main canal. At the end of this first terrace, built over the stream, were the principal loggias and reception rooms. On its other side this building opened on to the Rose garden, across which towered the high palace of the women's quarters, with its splendid views and airy bedrooms on the roof. Here, built into the side walls, a kitchen pavilion on one hand balanced rooms for guests on the other: while forty feet below lay the large fruit garden, the "bostan," or orchard, with the summer drawing-room delightfully "withdrawn" in the centre of the largest fountain tank.

THE TWO STYLES.

THIS garden, although built in Mughal times, now belongs to a Hindu Maharaja, and it must be remembered that two constantly intermingling styles are traceable in the history of Indian gardening. Both are primarily based on the central tree, fountain, or pavilion, and the four-went water-ways, or paths of the old Indian village plan. But the Central Asian water garden, brought into India by the Moslem conquerors, although not in the least exotic, as has been incorrectly suggested, for it reproduced an ancient Indian form, had at first, from the climate of its origin, quite another horticultural character to the Hindu gardens of the plains.

SPRING BULBS AND ORCHARD GARDENS.

THE Mughal garden in the hills was essentially a garden of spring flowers, a pleasure of Cherry, Quince, and Apple blossom, with Tulips, Anemones, Daffodils, Narcissus, Crown Imperials, and Iris scattered in the grass under the great Chenar avenues, or grouped in glowing parterres near the streams. Paeonies, Hollyhocks, Jasmine, and Carnations followed the spring bulbs, although even the Roses droop and fade before the first hot breath of the burning summer wind. But in autumn these orchard gardens, where the purple Grapes festoon the Poplar trees, are almost as lovely as in spring. So Babar thought long ago, when he saw the Garden of Fidelity, with the "Pomegranates hanging red on the trees," or that garden at Kabul, where he notes in his memoirs, "One Apple tree had been in excellent bearing. On some branches five or six scattered leaves still remained, and exhibited a beauty which the painter with all his skill might attempt in vain to portray."

THE NISHAT BAGH.

THE Nishat Bagh, true to its name, is the gayest of all Mughal gardens. Its twelve terraces, one for each sign of the Zodiac, rise dramatically higher and higher up the mountain side from the eastern shore of the Dal Lake in Kashmir. The stream tears foaming down the carved cascades, fountains play in every tank and watercourse, filling the garden with their joyous life and movement. The flower beds on these sunny terraces still blaze with colour—Roses, Lilies, Geraniums, Asters, tall growing Zinnias, and feathery Cosmos, pink and white. Beautiful at all times, when autumn lights up the Poplars in clear gold, and the big Chenars burn red against the dark blue rocky background, there are few more brilliant, more enchanting sights than the first view of Asaf Khan's Garden of Gladness.

The garden was built about the year 1620 by Jahangir's prime minister, the brother of his garden-loving Empress, the famous Nur-Jahan. It is about 600 yards long by about 300 yards wide. Exploring it terrace by terrace, as it

exists to-day, we may be able to arrive at some of the details of Indian gardening in Kashmir.

CHOICE OF SITE.

The Mughals, with their fine traditions, laid most stress on choice of site. All the finest Mughal gardens or their ruins are found most beautifully placed. Even the little Chasma Shahi, the Garden of the Royal Spring, perched high on the mountain side, over the Lotus fields of the Dal, although so small, hardly more than an acre and a half, from its plan and its marvellous view, is quite as attractive as its great rivals round the lake below. The river gardens at Bijbehara, Fadaï Khan's garden at Pinjor, Nur-Gahan's favourite Verinag, Lalla Rookh's garden on the Manasbal Lake, all illustrate some special theme. Achibal Bagh is an ideal site. Nothing can surpass the natural loveliness of the river gushing out of the honeycombed limestone cliff just at the point where the mountains intrude farthest on the plains. If I were asked where the most perfect modern garden on a medium scale could be devised, I should answer without hesitation, Achibal. Nowhere else have I seen such possibilities for the combined appeal of a stately stone-bordered pleasure, between ordered avenues of full-grown trees, and a natural rock and woodland upper garden, with haunting, far-reaching views, where the white wild Roses foam over the Firs and the boulders, rivalling the "great cascade" the traveller Bernier praised.

THE INFLUENCE OF THE PLAINS.

The scheme of the Mughal garden, based as it is on the most simple and scientific principles for an irrigated garden in a dry climate, stayed unchanged in the plains. But the fresh environment altered its aspect. The water became, on account of the heat, more and more the central motive. The Indian flora, too, so unlike that of Turkestan, gave a very distinctive character to the garden.

Strange as it may seem, few wild flowers are found growing in the upper Indian plains, for there, even in winter, the fierce sun burns into the ground. But the flower patches of the northern hills and meadows are replaced by deep-rooted blossoming trees, and these make up to some extent for the absence of the smaller herbaceous plants, their leafless boughs and bare twigs burst into a gorgeous flowering in the hot Indian spring, till the jungle glows like English Beech and Elm woods on a clear autumn day. Then in the plains there is the second flowering, the season of the rains, when the rank green growth chokes all but the tall grasses and ferns, and the Lotus flowers, with their lovely curving leaves, completely hide the surface of the ponds. Creepers flourish in the damp, dripping forests, where the gnarled, twisted limbs of the old Mangos are fringed with sweet scented Orchid sprays, as if swarms of little mauve and yellow butterflies were fluttering down to settle in the dim green shadows of the trees. The Hindu garden then was a cool woodland place. Its outstanding features were the flowering shrubs and trees, the creepers, and the aquatic plants: the Mango, Asoka, and Champaka groves, the Bignonia, Jasmine, and *Convolvulus* bowers, and the Lotus and Water Lilies floating on the ponds.

"THE FOUR CAUSES."

The question of the garden soil was carefully considered. It was placed under three heads and subdivided into six different colours. It would take too long to enumerate the different trees and plants considered most suitable to each soil. But an old Hindu writer closes with a remark, the truth of which, I think, all good gardeners who have struggled with bad soils will appreciate: "If any lasting and productive tree will be found on a different soil from that to which it is adapted, such casual growth is accounted for from the four causes, namely, that underneath the tree there might be a hidden treasure, or the tomb of a sage, or that the ruler of the country is fortunate and auspicious, or by the unwearied exertions and good conduct of the planter."

MOONLIGHT GARDENS.

Many fresh and charming ideas stepped into the Moslem garden with Akbar's Rajput queen. But the greatest change the Hindu influence wrought was the introduction of the moonlight garden—a change from the sunlit Turkish

gardens, with their Rose pergolas and glorious parterres, to moonlight Indian gardens of dark trees, white flowers, white paths, perfumes, and lights. The Hindu pleasure is planned essentially for evening enjoyment. Not that the Mughals failed to see the beauty of night. Babar, who so loved the glowing rings of the camp fires, had his Mahtab Bagh, one may be sure. But the Indian flowering trees are at their best in the hot weather and the rains, especially when the cool evening breeze brings out their perfume. Hindu ladies until recently rarely entered their gardens except at night.

DECORATIVE LIGHTING.

It follows that decorative lighting was, and is, a very distinctive feature in Indian garden craft, and one, from the nature of things, but little understood by Europeans. Now, what with the adaptability of electricity, and our modern French and English artists' obvious delight in the contrast of blue twilight and the rosy warmth of artificial light, the little lamps may once more gleam from under the waterfalls, and many other charming traits of Indian gardening be developed or revived.

MODERN GARDENING IN INDIA.

Horticulture, viewed as a science, flourishes in India. Botanical gardens and horticultural colleges are constantly improving well known shrubs and flowers, and acclimatising new ones. But, on the other hand, the use and beauty of design and the charm of garden symbolism have been almost lost sight of under our rule. This is not surprising when one remembers, as Mrs. Evelyn Cecil has so well pointed out, that the British Raj was being firmly established in India just at the time when the revolt against old gardens was strongest in this country. It was not likely, when it was the fashion to destroy whole avenues, and to obliterate the formal lines of parterres and stone-bordered pools at home, that those of India should be studied or admired.

It is only within quite recent years that the remarkable advance in horticulture (which we owe to societies like yours), hand in hand with the revived appreciation and development of architecture, is rapidly producing a new and yet more lovely style of English gardening.

I believe at this juncture we have much to learn from the art of the Indian garden. In the East it is impossible to foretell what delightful developments might arise from the combination of traditional Indian garden building with our modern needs and our modern wealth of flowers. Colour groupings, massing of Roses, and spring bulbs, and terraces devoted to a single kind of tree or flower, are Mughal fancies likely to appeal to Anglo-Indian gardeners. Our present feeling for stone or brick-built pergolas would renew an old tradition, and have full scope under the hot Indian sun. A revived and restrained use of tiles in the garden might prove a lovely feature of the modern Indian style; blue tiles under the blue-green water reflecting yet a deeper blue than the cloudless Eastern sky; flower-decked tiles set in garden gateway, or lining a fountain or a little garden well. Round Lahore beautiful examples of this Nakkashi work, as it is called, are to be seen. There are still one or two old workers left, but nowadays nobody wants their tiles. The aimless statues, which with European zeal we scatter up and down the land—the Maidan at Calcutta is thick with them—might find an appropriate and dignified repose in the alcoves of these architectural gardens. Ruskin, I think it was, points out how straight lines when partly clothed form the best foil to the grace of natural curves in plants and foliage, and the beautiful canals of Indian gardens, the long lines of the waterways and paths, hedged in by trees, produce a wonderful sense of stately dignity and peace, while the tranquil breadth of water repeats the flowers, trees, and buildings with a double magic charm, till the whole garden seems full of that mysterious beauty that comes of the sense of calm continuance, the result of quietude, part of that rhythm of harmonious change, through birth to death, and death to birth again, that special Eastern consciousness of universal life.

Fresh points of view and a change of technique give an impetus in every art: details may, with advantage, be transplanted and transformed, and among the details which a study of Indian

gardening might suggest to us at home are a closer harmony of house and grounds, the treatment of water, the moonlight garden of white perfumed flowers, the use of decorative lighting, and a fuller realisation both in spring and in autumn of the orchard garden.

THE DISCUSSION.

A particularly interesting discussion then followed. Sir Krishna Gupta and Mr. Ali Baig, members of the Indian Council in London, spoke eloquently and at pleasant length, expressing their extreme gratification at Mrs. Villiers-Stuart's lecture, and their pleasure in seeing such excellent views of the old Indian gardens. Gardening in India was now far from being such a general phase of the daily life of the people as in England, and they hoped that in the near future a wave of gardening enthusiasm would sweep over their country. At Delhi, the new capital of the Empire, attention is being paid to gardening, and the influence of this departure will undoubtedly be great, but India is a vast country, and before any general garden spirit can be observed examples must be set in various other centres. But for the consummation of their desires a large amount of money would be required, and in the Indian Empire the necessary funds for such work were always difficult to obtain. It would be quite natural, they observed, to attempt to compare the gardens of India, which have been so well portrayed by Mrs. Villiers-Stuart, with English gardens. But there could be no real comparison, because there is no gardening in India as it is understood in this country. The horticulture of the Eastern Empire is more largely architectural than horticultural, and the essentials there are an open situation, so as to provide views and to admit the cooling breezes of evening, and running water to cool the air. For this latter reason the fountains are always numerous, and of small size. The magnificent jets of water occasionally seen in England have no counterpart in India, for there fountains and running water are looked upon in their utilitarian rather than aesthetic aspect. The many fountains projecting fine sprays of water play a very necessary part in cooling the air. The typical garden in India is a place of seclusion, and is used more especially in the evening, when the great heat of the day has passed. In the past the chief stimulus to garden building has come from Turkestan and Persia; later the Portuguese and Dutch introduced new shrubs and flowers, and it would be interesting to speculate on the gardens of the future, which it is very probable will be largely what may be termed English in style. But the cool green lawns and rich verdure of the trees can scarcely be embodied in any general garden scheme in India, and their place must be taken by running water and fountains.

In the course of an interesting speech Col. Sykes drew comparisons between the gardens of Persia and those of India. In the former country the terraces are usually seven in number; this number being chosen to symbolise the seven planets. As in India, water is always a great feature of the gardens, and anyone, he said, who had ridden twenty or more miles across the exceedingly hot and treeless plains of that country, under the fierce summer sun, could appreciate to the full the delightful coolness afforded by the sprays of the many fountains. As in India, the gardens of Persia always contain fruit trees, and of these the most common are the Peach, Fig, and the Grape vine.

Mr. J. Cheal spoke of his great interest in the lecture, and of his hopes that in the near future he might see some of those interesting gardens. He felt that in England greater use might be made of hardy fruit trees for ornamental purposes, a sentiment which was shared by Mr. Arthur Sutton and by Mr. H. R. Darlington. In conveying the thanks of the club to Mrs. Villiers-Stuart for her lecture, Mr. A. Worsley expressed his opinion that gardening in India owed more than was generally realised to Portugal, for he had been impressed by the unmistakable signs of Portuguese influence, and emphasised the fact that in Portugal gardening was everywhere a prominent feature. He sketched the history of the word garden, which he found to have originally meant an enclosed yard. The older gardens always were enclosed

yards, and, as in India, were places of secluded rest or promenade. As greater security spread over a country, so the garden generally spread away from the dwelling. He agreed with the previous speakers in that there be no proper comparison between the gardens of this country and those of India, for the latter are essentially places of rest and retreat, whilst we look upon the garden as a place to grow plants for their beauty or use, or, as often happens, because of their rarity.

SCOTTISH HORTICULTURAL.

MAY 5.—The monthly meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 5th inst. Mr. King, the president, was in the chair, and there was an attendance of 90 members.

Mr. ROBERT FIFE, of Messrs. Dobbie and Co., Edinburgh, gave an account, with lantern illustrations, of some experiments in the manuring of Sweet Peas with artificial manures which he had conducted last year, and which showed some interesting results. The plants were grown in pots, in pure pit sand, and photographs of the variously treated plants (which were all of the same variety) and their roots were thrown on the screen. The sand was as pure as could be obtained of its kind, and contained practically no humus. Plants treated with nitrogenous manures gave only slightly better results than with no manure, but the leaves were of a darker green and the nodules were but sparingly developed on the roots. With superphosphate of lime alone the leaves were large and the plants were of strong growth, with an abundance of nodules on the roots. With sulphate of potash alone the leaves were small and dark green, and the plants were of moderate growth, with a plentiful development of nodules on the roots. With sulphate of magnesia (Epsom salts) alone the leaves were of normal colour, the plants were of good growth, and there was a moderate production of nodules on the roots. Sulphate of potash and superphosphate of lime in combination gave good growth and colour of leaf, with a plentiful supply of nodules on the roots. But the best results were with nitrogen, phosphate and potash in combination. In the last-mentioned cases the addition of neither magnesia nor sulphate of iron made any appreciable difference.

The exhibits were:—"Greened" tuber of Potato Dalhousie Seedling, weighing 3 lb., exhibited by Mr. WM. GRAY, Brachead Farm, Crumond Bridge; Cabbage, Broccoli and Rhubarb, exhibited by Mr. CAIRNS, Murieston; and Tulip with four flowers, exhibited by Mr. R. MORRIS, Edinburgh.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 16.—Committee present: Rev. J. Crombleholme (in the chair), Messrs. Ashworth, J. Bamber, J. C. Cowan, J. Cypher, A. G. Ellwood, J. Evans, A. Hanmer, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, W. J. Morgan, C. Parker, W. Shackleton, H. Thorp, A. Warburton, Z. A. Ward, G. Weatherby, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Odontoglossum triumphans var. "Royal," *Odontioda Charlesworthii sanguinea*, *L.-C. Ycsuvius* (bletchlevensis × *Dominianum*), and *Phaius tuberosus*, all from R. ASHWORTH, Esq.

Miltonias Bleuana alba and *rosa* var. "Leeana," and *M. vexillaria Lyoth magnifica* (chelsense × G. D. Owen), both from W. R. LEE, Esq.

Laelio-Cattleya Fred Boyle var. "Kerchorne" (*C. trianae* alba × *L. anceps* alba), *Cymbidium Pawwelsii* var. *Idcol*, from JOHN LEEMAN, Esq.

Odontoglossum illustrissimum var. "Purpleum," and *O. eximium* var. "Nero," from WM. THOMPSON, Esq.

O. Mrs. Phoebe Fletcher (*eximium* × *amabile*), from R. LE DOUX, Esq.

AWARDS OF MERIT.

O. amabile var. "Princess," *O. Phoebe* var. "Brunette," *O. Harvingtonse* var. "Emperor,"

O. excellens var. "Gold Crest," *O. eximium* var. "Nero," *O. Adrianae* var. "Brunum," all from WM. THOMPSON, Esq.

Brasso-Laelio-Cattleya Joan (B.-L. Mary Gratrix × *C. Octave Doin*), *Brasso-Cattleya Queen Alexandra* "Bearwood" var. *B.-C. gloriosa* (*Aphrodite* × *Digbyana*), all from Col. J. RUTHERFORD.

O. amabile Her Majesty and *O. "Merl Dene"* var., both from A. J. OAKSHOTT, Esq.

Odontioda Brewii var. *auriferum*, from R. ASHWORTH, Esq.

APRIL 30.—Committee present: Rev. J. Crombleholme (in the chair), Messrs. J. Bamber, J. Cypher, A. Hanmer, J. Howes, J. Lupton, C. Parker, F. K. Sander, W. Shackleton, H. Thorp, A. Warburton, Z. A. Ward, G. Weatherby, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Cattleya Mendelii alba Ashlands var., and *Laelia purpurata lineata*, both from R. ASHWORTH, Esq.

Odontioda Flamingo and *Odontoglossum* × *Princess Mary*, both from WM. THOMPSON, Esq.

O. × Pharos, from JOHN LEEMAN, Esq.

Miltonia Charlesworthii Marfield var., a fine flower, with intense blotch on the lip, from R. LE DOUX, Esq.

BOTANICAL CERTIFICATE.

Cirrhopetalum Cummingii, from R. ASHWORTH, Esq.

AWARDS OF MERIT.

Odontoglossum crispum Christopherson, *O. nebulum* (*nebulosum album* × *asperum*), *O. Jasper Purple King*, *O. crispum flavicolum*, *O. Raymond*, *O. Fascinator wiltonense*, all from WM. THOMPSON, Esq.

O. Mendelii Brilliant, *O. caudatum aureum*, *O. crispum Puritan*, *O. × Darkie*, all from R. ASHWORTH, Esq.

O. × Domingo de Laringo (*Harryanum* × *illustrissimum*), *O. ardentissimum Minnie*, *O. Lambeauianum Dr. John Utting*, all from R. LE DOUX, Esq.

O. eximium Cleome, from JOHN LEEMAN, Esq. *Miltonia Bleuana Broadwood Variety*, from Col J. RUTHERFORD, M.P.

CULTURAL COMMENDATION.

To Mr. GILDEN, gardener to R.J. Ashworth, Esq., for a plant of *Dendrobium Victoria Regina*.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

MAY 11.—The Committee met on the 11th inst.: Mr. A. BEDFORD presided. A member who joined the society in 1877 and lapsed in 1912 had a sum of £107 15s. standing to his credit, this being passed for payment to him. Three members were also allowed to withdraw double the amount of interest, amounting to £13 10s., and one member £5 from his deposit account, whilst the sums of £36 and £29 5s. 10d. were passed for payment to the nominees of two deceased members. A grant of £2 was made to a member in distress. The sick pay for the month on the ordinary side amounted to £72 12s., and on the State £32 19s., with maternity benefits £10 10s.

PERPETUAL-FLOWERING CARNATION.

APRIL 29 and 30.—The spring show of the Perpetual-Flowering Carnation Society, which was held at the Winter Gardens, Bournemouth, was an unqualified success. Local exhibitors did very well, especially Mr. A. E. USHER, of Blandford, who showed a number of fine blooms. The opening ceremony was performed by Sir Merton R. Cotes, and Sir Daniel Morris, K.C.M.G., President of the Bournemouth Horticultural Society, was also present.

The classes were numerous and well contested. First prizes were won by Mr. A. E. USHER for a decorated épergne, for five vases (special prize presented by G. Mount and Sons), for twelve of Messrs. Wells' blooms (silver challenge cup presented by that firm), twelve blooms of Young and Co. (special prize given by Messrs. Young) and

several others. He was also successful in gaining the Silver Challenge Cup presented by Mrs. F. Norman, Much Hadham, for one vase of British-raised seedling Carnations. In the open classes, Mr. C. ENGELMANN, Saffron Walden, was successful in gaining the first prize (gold medal and 60s.) for a group comprising twelve varieties of cut Carnations; the challenge cup presented by Mr. J. S. Brunton for twelve blooms of British novelties; the Challenge Cup presented by the American Carnation Society; and other awards. Mr. A. F. DUTTON, Iver, won the Challenge Cup presented by Mr. Geo. Monro, jun., for twelve vases of twelve varieties, and Messrs. G. WATTS AND SONS, of Bournemouth, obtained first prizes for a decorative basket, and brides' and bridesmaids' bouquets.

The exhibits were almost uniformly of good quality, which made the judging in some cases difficult. The arrangements for the exhibition had been excellently carried out, and a large number of visitors attended.

DEBATING SOCIETIES.

BRITISH GARDENERS' (Leamington Branch)

—A meeting of the Leamington branch of the B.G.A. was held on the 25th ult., when a lecture on *Cbrysanthemums* was delivered by Mr. Turner, East Hadden Hall Gardens, Northampton.

READING GARDENERS'.—At the fortnightly meeting of this association, which was held in the Abbey Hall on Monday, 20th ult., Mr. J. T. Tubb presided, and there was again a good attendance. The evening was devoted to the following competitions:—Vase of flowers (open to head gardeners, single-handed gardeners, and foremen only): The 1st prize was awarded to Mr. E. Barnes; 2nd, Mr. F. W. Costin. Vase of flowers (head gardeners, single-handed gardeners and foremen not allowed to compete): Mr. R. Baker was successful; 2nd, Mr. D. Petterson. Bowl of flowers arranged for effect (open to head gardeners, &c.): Mr. J. Wynn secured the 1st award; 2nd, Mr. C. Goodchild. Bowl of flowers arranged for effect (head gardeners, &c., not allowed to compete): Mr. H. Randall was placed 1st; 2nd, Mr. J. Lloyd. This meeting had been selected for the annual hospital night, when members bring flowers which are the next day sent to the Royal Berkshire Hospital and the Workhouse Infirmary. Nearly one hundred bunches were contributed. A collection on behalf of the funds of the Royal Berkshire Hospital was made by Mr. E. J. Dore, the association's representative, the sum of £2 3s. being thus realised.

WATFORD HORTICULTURAL.—The monthly meeting of this society was held on the 17th ult., when Matthew Arnold, Esq., presided. Mr. A. Harrison gave a lecture on "Orchids," illustrated with lantern slides. He also exhibited a collection of Orchids in pots, and a number of cut blooms.

BIRMINGHAM AND DISTRICT GARDENERS'.—The meeting on the 20th ult. concluded the spring session of fortnightly meetings. Mr. J. Webb, gardener to W. B. Kenrick, Esq., Metchley House, Harborne, delivered a lecture on "Hardy Flowering Trees and Shrubs." Originally it had been his intention to devote a paper upon this occasion to Alpine plants, but as the forthcoming visit of the society to Mr. W. A. Cadbury's Alpine garden, which will take place in May, will also include an illustrated lecture upon "Alpine Plants" by his gardener, Mr. Bick, Mr. Webb decided to address the meeting on hardy flowering trees and shrubs. By conducting experiments with *Almond*, *Cerasus Avium*, *Daphne Mezereum album* and *rubrum*, *Forsythia suspensa*, *Honeysuckle*, *Jasminum*, *Prunus Pissartii*, *P. triloba* fl. pl., and *Ribes atrosanguinea*, he had been able to obtain flowers in December and January. By cutting a promising branch of Sweet Almond from a tree in the open, and placing it in water in the forcing house for five or six weeks a delightful spray of blossom suitable to adorn any table could be obtained. Practical experience had revealed to him that with some of these trees the earlier growths yielded better blooms, and in others the later growths did better. As standards for borders *Ribes*, *Skimmia japonica*, *Hydrangeas*, *Laburnum*, *Viburnum Tinus* (*Laurustinus*), and *Lilacs* were exceedingly useful. *Cytisus Andreanus* could be utilised for making a neat finish in dry situations such as are found beneath Pine or Fir trees; while *Berberis aquifolium* (*Mahonia*), *B. Darwinii*, *B. stenophylla*, and *B. Thunbergii*, together with *Perennetya speciosa*, and other of the dwarfier shrubs furnish excellent plants for beds. After dealing separately with each of the various species, and describing the best methods of growing the plants, he concluded by giving a selection of the best varieties of *Rhododendrons* for cultivation in town gardens.

BRISTOL AND DISTRICT GARDENERS'.—The sixteenth annual meeting of this association was held on the 30th ult. Mr. J. Bastin presiding. The annual report showed that the association had enjoyed a record year, both from a financial point of view, and in the increase of members. The officers were elected as follows: President, Colonel Cary Batten, J.P.; chairman, Mr. Jennings; vice-chairman, Mr. Woodward; hon. sec. and treasurer, Mr. Scott; assistant secretary, Mr. A. Combes. The special prizes offered by Messrs. Brown and Jennings for the greatest number of points awarded for non-competitive exhibits, were won by Mr. Bird (1st), Mr. Jennings (2nd), and Mr. Woodward (3rd).

The Under-Gardeners' special prizes given by Messrs. Scott and Shaddick were won by Mr. Extence (1st), and Messrs Barrow and Daly (equal 2nd).

CROYDON AND DISTRICT HORTICULTURAL.—A lecture on "Insect Pests" was delivered by Mr. G. J. Nimes at a recent meeting of this society. He first described the appearance and habits of the aphid, or "green-fly," sketching briefly the life history of the pest, and showing how in the hover, or hawk-fly, it finds a formidable enemy. He also made allusion to the "spittle-fly," earwig, and many other insect pests, and gave directions for their destruction. A meeting of this society was held on the 5th inst. The evening was devoted to studies with the microscope relative to plant life.

WARGRAVE AND DISTRICT GARDENERS.—The last meeting of the spring session was held on Wednesday, April 22. A competition in table decorations took place in two sections, one for head gardeners and one for journeymen. The winner of the 1st prize in the class for head gardeners was Mr. Hinstead; the successful journeyman was Mr. Plumridge. Messrs. John Waterer, Sons, and Crisp sent an effective non-competitive group of hardy plants.

SOUTHAMPTON AND DISTRICT GARDENERS.—The usual monthly meeting of this society was held on the 30th ult., Prof. E. S. Lyttel presiding. A lecture was given by the president, Mr. H. E. Molyneux, on "The Morality and Sagacity of Plants."

WATFORD HORTICULTURAL.—A meeting of this society was held on the 8th inst., when W. A. Smith, Esq., presided. Mr. W. Waterton read a paper on "Celery and Leek Culture."

BATH GARDENERS.—At the meeting held on the 27th ult. Mr. Elkes, of the Bristol Gardeners' Society, delivered a paper on "Organic and Inorganic Manures." Mr. T. Parrott occupied the chair. The annual outing will take place on July 23, when the Royal Gardens, Frogmore, will be visited.

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

- Mr. J. Porter,** for the past 12 months Foreman at Hilfield Park, Hertfordshire, and previously at Shottersbrooke Park, as Gardener to H. M. HARFORD, Esq., Merryhill House, Bushey, Hertfordshire.
- Mr. W. J. Buckle,** for the past 5 years foreman at Blankney Hall, Lincoln, as Gardener to Mr. CLAYTON SWAN, Welbourn Manor, Lincoln. [Thanks for Is. for R.G.O.F. box.—Eds.]
- Mr. Jas. Cunningham,** for several years Gardener at Abercainey, Crieff, and formerly General Foreman at Scone Palace, Perth, as Gardener to Sir ARCHIBALD EDMONSTONE, Bart., Dumtreath Castle, Blenheim.
- Mr. T. Lloyd,** late Gardener to Sir OFFLEY WAKEMAN, Bart., Yeaton Peverey, near Shrewsbury, Shropshire, as Gardener to ROSCOE BRUNNER, Esq., Belmont Hall, Northwich, Cheshire.
- Mr. J. Smith,** for 8 years Gardener to H. F. SEYMOUR, Esq., Potterells, Hatfield, Hertfordshire and Thornhill, East Grinstead, previously in the R.H.S. Gardens, Chiswick and Wisley, as Gardener to A. P. HOSKINS, Esq., Linholme, Holmbury St. Mary's, Surrey. [Thanks for 2s. for R.G.O.F. box.—Eds.]
- Mr. Wm. Evans,** Gardener for the past 9 years to R. F. MOSLEY, Esq., Croft House, Sheffield, as Gardener to J. DYMOND, Esq., Burntwood Hall, near Barnsley, Yorkshire.
- Mr. C. Ware,** for 18 months Gardener to V. FLEMING, Esq., M.P., Braziers Park, Ipsden, Oxfordshire, as Gardener to J. CAMPBELL-BANNERMAN, Esq., Hutton Court, Maidstone. [Thanks for 2s. for R.G.O.F. box.—Eds.]

- C. A. NOBELIUS, Gumbrook Nurseries, Emerald, Victoria, Australia.—Fruit Trees and Nursery Stock.

SCHEDULES RECEIVED.

Southampton Royal Horticultural Society.—The Rose show of this society will be held at South Stoneham House on Wednesday, July 1; the summer and Carnation show will be held on Tuesday and Wednesday, July 21 and 22, at the Royal Pier; and the autumn show will be held at the Drill Hall, St. Mary's Road, on Tuesday and Wednesday, November 3 and 4. Secretary, Mr. C. S. Fudge, Silverdale Road, Southampton.

Llandudno and District Horticultural Society.—The third annual show of this society will be held in the Town Hall, Llandudno, on Wednesday, July 15. Secretary, Mr. Alfred Conolly, Barrowby, Llandudno.

Newcastle-upon-Tyne Flower Show.—This show will be held on Tuesday, Wednesday and Thursday, August 25, 26 and 27, in the Recreation Ground, North Road. Secretary, Mr. R. H. Newton, 24, Gainger Street, West, Newcastle.

Morley and District Paxton Society.—The tenth annual Chrysanthemum show of this society will be held on Saturday, November 21. Secretary, Mr. S. J. Wormald, Zion House, Morley.

Paisley Florist Society.—The Chrysanthemum Show of this Society will be held on Saturday, September 19. Secretary, Mr. F. Ferguson, 40, High Street, Paisley.

Haywards Heath and Mid-Sussex Horticultural Society.—The 26th exhibition of this society will be held on July 22 in Victoria Park, Haywards Heath. Secretary, Mr. Geo. Prevett, The Rosery, Franklyn Road, Haywards Heath.

Dover Horticultural Society.—The summer show of this society will be held on Thursday, July 2, and the autumn show on Tuesday and Wednesday, November 10 and 11. Secretary, Mr. C. P. Tomlin, 41, Folkstone Road, Dover.

Croydon Chrysanthemum Society.—The 27th annual show will be held on Wednesday and Thursday, October 28 and 29, at the Central Baths Hall, Scarbrooke Road, Croydon. Secretary, Mr. F. Oxtoby, The Cottage, Coombe Lodge, Coombe Road, Croydon.

Streatham Sweet Pea and Rose Society.—The sixth annual exhibition will be held at Streatham Town Hall on Thursday, July 2. Secretary, Mr. David Gibb, 152, Sunnyhill Road, Streatham.

Weybridge, Walton-on-Thames and District Rose and Horticultural Society.—The 16th annual summer exhibition of this society will be held at the Old Palace Gardens, Weybridge, on Wednesday, July 8. Secretary, Mr. C. Rowland, Station Road, Weybridge.

Watford Horticultural Society.—The summer show will be held at Little Cassibury, on Wednesday, July 22, and the autumn show will be held in the Clarendon Hall, Watford, on Wednesday, November 4. Secretary, Mr. W. Waterton, Heath Farm House Gardens, Watford.

Glasgow and West of Scotland Horticultural Society.—The flower show of this society will be held in the Exhibition Hall (Zoo Buildings), 48, New City Road, Glasgow, on Wednesday and Thursday, September 2 and 3. Secretary, Mr. Hugh M. Mackie, 124, St. Vincent Street, Glasgow.

Brighton, Hove and Sussex Horticultural Society.—The summer show of this society will be held on Tuesday and Wednesday, August 18 and 19, at the Dome Corn Exchange, and Western Lawn; and the Chrysanthemum Show will be held at the Dome and Corn Exchange, on Tuesday and Wednesday, November 3 and 4. Secretary, Mr. A. J. Gaston, 170, Springfield Road, Brighton.

Bletchley and Fenny Stratford Horticultural Society.—The fifth annual show will be held on Monday, August 3, in the grounds of Bletchley Park. Secretary, Mr. Thomas Best, Bletchley.

Windsor, Eton and District Chrysanthemum and Horticultural Society.—The twenty-third annual exhibition of this society will be held in the Royal Albert Institute, Windsor, on Friday, November 6. Secretary, Mr. G. E. Keer, Meadowlea, Datchet.

Bradford and District Chrysanthemum Show will be held in St. George's Hall, Bradford, on Friday and Saturday, November 13 and 14. Secretary, Mr. H. Spencer, Horton Park, Bradford.

Oldswinford Horticultural Society.—The second annual vegetable, flower, and fruit show will be held in the Parish Rooms, Oldswinford, on Thursday, August 27. Secretaries, Messrs. Lambert and Caldwell, Parish Rooms, Oldswinford.

County Clare Horticultural Society.—The annual exhibition of fruit and farm produce will be held on October 1, in the Court House, Ennis. Secretary, Rev. R. Scott, The Manse, Ennis.

Bolton Horticultural and Chrysanthemum.—The twenty-eighth exhibition of this society will be held in the Town Hall on Friday and Saturday, November 20 and 21. Secretary, Mr. Geo. Corbett, Heaton Grange Gardens, Bolton.

Weston-super-Mare and District Chrysanthemum Society.—The annual exhibition will be held in the Knightstone Pavilion on Thursday, October 29. Secretary, Mr. C. E. Masters, 4, South Parade, Weston-super-Mare.

The Sutton Rose Society.—The thirty-third exhibition will be held in the Public Hall, Sutton, on Saturday, July 4.

Horticultural Exhibition to be held in conjunction with the Lincolnshire Agricultural Show, at Boston, on Tuesday and Friday, July 16 and 17. Secretary, Mr. Peter Blair, Trentham Gardens, Stoke-on-Trent.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending May 9, is furnished from the Meteorological Office:—

REMARKS ON WIND AND WEATHER.

May 12, 1914.
During the earlier half of the week, when a large barometrical depression extended over the United Kingdom from the Atlantic, the wind on all but our extreme Northern Coasts was south-west or west, and in the Western and Southern districts it blew with considerable strength. Rain was frequent, but the amount was, as a rule, not large. Thunderstorms occurred on the 5th at several places situated in the North and East of Great Britain. The central portion of the disturbance passed on the same day eastward across Scotland, but in its rear numerous small secondaries were developed, and on the 7th and 8th the gradual deepening of one of these systems over Scotland was attended by a heavy fall of rain in the Northern and Central Districts. At Fort Augustus the total quantity for the two days amounted to 70 millimetres, and at Gordon Castle to 62 millimetres, thunderstorms occurring at the same time in many parts of England. On the 8th and 9th, when the centre of the disturbance passed to the North Sea, the wind, which had previously been variable, shifted to the north-westward, and blew with the force of a gale in many places. Temperature at the same time decreased rapidly, and on the 9th a slight fall of snow occurred in several parts of North Britain.

WEATHER IN WEST HERTS.

Week ending May 13, 1914.
A Cold and Gloomy Week. The first day proved warm, but since then the days have all been cold, and on the coldest day the temperature in the thermometer screen did not rise above 47°, or 12° below the average maximum reading for the time of year. On the coldest night the exposed thermometer registered 5° of frost. The ground is now 2° colder at 2 feet deep, and 3° colder at 1 foot deep, than is seasonable. Rain fell on five days, and to the total depth of 3 inch. Small quantities of rainwater have passed through the bare soil percolation gauge on each of the past six days. The sun shone on an average for 3½ hours a day, which is 2½ hours a day short of the average duration for the early part of May. The wind was rather high at the beginning of the week, but in no hour did the mean velocity exceed sixteen miles—direction west. The average amount of moisture in the air at three o'clock in the afternoon exceeded a seasonable quantity for that hour by as much as 12 per cent. The first roses to flower in my garden in the open ground were Rosa rubella on the 5th inst., Rosa alpina on the 8th inst., and Rosa sericea pteracantha on the 10th inst. The two latter dates are respectively a week and eleven days earlier than last year. E. M., Berkhamsted, May 13, 1914.

APRIL.

Remarkably Warm, Dry, and Sunny.—This was with one exception (1893) the warmest April I have yet recorded here during the past twenty-eight years. The night readings were variable, but on the whole rather higher than is seasonable. The days were remarkable, being, with three exceptions, warmer than is seasonable. In fact, the mean maximum reading (60°) was with one exception higher than in any of the past twenty-eight Aprils. On the warmest day the temperature in the thermometer screen rose to 79°, and on the two coldest nights the exposed thermometer registered 8° of frost—the former being, with two exceptions, higher than in any April during the past twenty-eight years, and the latter the highest extreme minimum in April for ten years. Rain fell on only eight days—all but one being in the first ten days of the month—to the total depth of one inch, which is not much more than half the average fall for April. No snow fell during the month. The sun shone on an average for 7½ hours a day, which is 2½ hours a day in excess of the average duration for the month, making this, with two exceptions, the sunniest April during the past twenty-eight years. The winds were on the whole rather light. In the windiest hour the mean velocity reached twenty-one miles—direction W. The average amount of moisture in the air at three o'clock in the afternoon fell short of a seasonable quantity for that hour by 4 per cent.—E. M., Berkhamsted, May 6, 1914.

MARKETS.

COVENT GARDEN, May 15.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices, including Anemone St. Bridg., Arums (Richardias), Carnations, Gardenias, Gladioli, and others.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and their prices, including Adiantum Fern, Agrostis (Fairy Grass), Asparagus plumosus, and others.

Foreign Flower Market.

Table listing foreign flower market prices, including Anemone fulgens, Marguerites, and others.

are seen in greater variety; the variety The Bride is now in a better condition, and the quality of other sorts is improving daily. Irises in all colours are plentiful, also Double White Narcissus, which is seen in better condition. There is a good supply of White and Pink Gypsophila. Of Liliums, L. Harrisi is most in demand; L. speciosum rubrum and L. s. album are very scarce.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various plants in pots and their prices, including Aralia Sieboldii, Araucaria excelsa, Asparagus plumosus, and others.

REMARKS.—The cold weather has influenced the sale of plants, more especially of Pelargoniums and hardy roots. Marguerites, Heliotropiums, Fuchsias, Pelargoniums, and Rhodanthe are all arriving in good condition. Pink Verbena Miss Willmot is on sale, but not the scarlet variety.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices, including Apples, Bananas, Cherries, Dates, Figs, Grapes, Lemons, and others.

REMARKS.—There have been received from Australia 147,000 cases of Apples, Pears, Grapes and Plums, the bulk of the fruits being in an excellent condition. Consignments of fruit from Cape Colony amounted to about 6,000 packages, the bulk consisting of Grapes. Supplies of Grapes from home growers and the Continent are increasing daily. Peaches and Nectarines are available in fairly large quantities. The market is better supplied with Figs and Melons. Continental growers are sending fine samples of Cherries packed very attractively in small boxes. Gooseberries on sale include some fine samples. English Tomatoes are arriv-

ing in larger quantities, and Tomatoes from Teneriffe are very good in quality. Forced vegetables available include Cucumbers, Beans, Peas, Mushrooms, New Potatoes and Marrows. English Asparagus is more plentiful, but Continental growers are sending fewer supplies of this vegetable. Onions are arriving from the following sources:—Canary Islands, Egypt, and Lisbon, but the stocks are small, and the prices very high. Spring Onions are now available. Of all ordinary vegetables there is a fairly plentiful supply with the exception of Broccoli.—E. H. R., Covent Garden, May 15, 1914.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices, including Artichokes, Asparagus, Beans, Broccoli, Cabbages, Carrots, Cauliflowers, Celery, Chicos, Cucumbers, Endive, Garlic, Horseradish, Leeks, Lettuce, and others.

Table listing Old Potatoes and their prices, including Blacklands, Dunbar-Red soil, and others.

Table listing New Potatoes and their prices, including Jersey, Lisbon, and others.

REMARKS.—Trade in old Potatoes remains fairly firm. There are few consignments, and stocks in the market are becoming much fewer. Business in new Potatoes is steady, and prices will drop next week.—Edward J. Newborn, Covent Garden and St. Pancras, May 15, 1914.

TRADE NOTE.

WM. FELS AND SON, LIMITED.

This new company was registered on April 30, by Gascotte and Fowler, 1, York Buildings, Adelphi, W.C. Capital, £4,000, in £1 shares (2,000 Preference). Objects: To take over the businesses of nurserymen, seedsmen, florists, gardeners and horticulturists carried on by A. H. Fells, A. Fells and W. F. Langford, trading as William Fells and Son, at Hitchin and Letchworth, Herts, and by W. A. Holmes, at Station Road, Letchworth. Private company.

Obituary.

WILLIAM EARP.—Mr. William Earp, gardener at Hume Towers, Bournemouth, for the long period of 42 years, died at Barton Road, Bournemouth West, on the 6th inst., at the ripe age of 82. Previous to his appointment at Hume Towers he was for five years gardener at Lighton House, Westbury, Wiltshire. In his younger days he was foreman at the Garstone Vineyards, Liverpool, under the late Mr. James Meredith, and subsequently was for two years engaged in Grape growing at

Morristown, U.S.A. To the older generation of gardeners Mr. Earp will be remembered as a successful exhibitor at such places as Trowbridge, Crystal Palace, Alexandra Palace, and Bath, competing often against the famous Mr. Coleman, of Eastnor Castle. Mr. Earp was a vice-president of the Bournemouth Gardeners' Mutual Improvement Society, and a member of the Bournemouth Chrysanthemum Society. He resigned his appointment at Hume Towers two years ago, when his employers granted him a pension.

PHILIPPE VAN TIEGHEM.—We learn with regret of the death, at the advanced age of 75, of one of the most distinguished botanists, Mr. Philippe Van Tieghem, who held for many years the professorship of botany in the Museum of Natural History and in the Institute of Agriculture (Paris). Besides being the author of many memoirs, Van Tieghem produced what is in many respects the best modern textbook of botany. Although most of his recent work related to the anatomy of plants, Van Tieghem's researches covered an extraordinary wide range; some of his earliest work was done on Fungi. In addition to his other labours he edited for many years the botanical part of the *Annales des Science Naturelles*, and held since 1877 the office of Permanent Secretary of the Academy of Science.

possession with six expanded inflorescences and another spike developing.

INSECTS: *L. B. P., Lynton.* The insects are clay-coloured weevils. Place portions of root-vegetables or Cabbage-leaves as traps, and hunt for the creatures at night, for they feed when it is dark. Shrub next week.

LARCH DAMAGED: *P.* The shoots have been injured by aphides, which may be checked by spraying with soft soap and paraffin emulsion. This specific is made as follows: Take a quantity of soft soap, place it in the bottom of a pail, and pour in paraffin. With the hand work the paraffin and soap in together until the soap will absorb no more paraffin, when the superfluous liquid may be discarded. It will then be found that the soap and paraffin will dissolve in water without the oil floating on the top. A full handful of the mixture should be dissolved in a pail of water.

MUSHROOMS AND SLUGS: *F. J.* A dressing of soot in a reasonable quantity would not damage the growth of Mushrooms to such an extent as you complain. But its use is not to be recommended. The best way to eradicate slugs on Mushroom beds is to place a few young Cabbage or Lettuce leaves as traps and to search for and destroy the slugs at night.

NAMES OF PLANTS: *H. E. T. and Son.* *Ilex dipryrena.*—*C. E. B.* *Prunus Padus* (Bird Cherry).—*W. A.* *Prunus Pseudocerasus* var. *flor. luteo.*—*Somerset.* 1, *Coelogyne cristata*; 2, *Dendrobium nobile*; 3, *Xanthoceras sorbifolia*; 4, *Lithospermum* sp.? too faded to identify; 5, *Piptanthus nepalensis*; 6, *Iberis semper-virens.*—*F. R.* 1, *Epimedium alpinum*; 2, *Prunus Padus*; 3, *Daphne Cneorum*; 4, *Cytisus purpureus*; 5, *Geranium phaeum*; 6, *Andromeda polifolia*; 7, *Daboccea polifolia.*—*W. B.* *Bryanthus empetrifolium.*—*W. G. W.* the Orchid from Rhodesia is *Ansellia gigantea.* It is the light-coloured form of *A. africana* which extends to Natal, whilst the typical, dark-coloured form *A. africana* extends through tropical Africa to the extreme west. The difference in colour and habit warrants the distinctive name of *A. gigantea.*—*J. F. Dancer.* 1, *Viburnum tomentosum*; 2, *Crataegus coccinea.*—*J. Shaxted.* 1, *Exochorda grandiflora*; 2, *Akebia quinata*; 3, *Pyrus floribunda atrosanguinea*; 4, *Elaeagnus multiflora*; 5, *Prunus acida* variety; 6, *Spiraea arguta.*—*T. S. N. A.* 1, *Exochorda Albertii*; 2, *Ceanothus dentatus*; 3, *Neviusia alabamensis*; 4, *Rosmarinus officinalis (prostratus)*; 5, *Coronilla Emerus*; 6, *Lepidium latifolium*; 7, *Genista hispanica*; 8, *Kalmia glauca*; 9, *Elaeagnus longipes*; 10, *Pyrus floribunda*; 11, *Phlox subulata*; 12, *Piptanthus nepalensis.*—*Miss G.* 1, *Ribes aureum*; 2, *Solanum crispum.*—*T. Knight.* 1, *Ribes aureum*; 2, *Exochorda grandiflora*; 3, *Aspidium angulare*; 4, *Oncidium divaricatum*; 5, *Saxifraga caespitosa*; 6, *Ionopsidium caule.*—*F. F. A.* 1, *Lastrea varia*; 2, *Pteris longifolia*; 3, *Adiantum hispidulum*; 4, *Asplenium cicutarium*; 5, *Davallia bullata.*

NAMES OF FRUITS: *Doubtful.* The fruits were decayed; they resemble Newton Wonder.—*T. Taylor.* Hornead's Pearmain.

PEACH CURL: *T. K.* See reply to *H. B.* in the last issue, p. 324; also note in "Home Correspondence," p. 336.

PEACH LEAVES: *A. W. P.* The small, round patches of diseased tissue which have in some cases fallen out and left small holes are caused by the fungus *Cercospora circumscissa*, known popularly as the "Shot-hole fungus." Spray the trees at intervals of a week with self-boiled lime sulphur wash, which is prepared as follows:—Take 1 lb. flowers of sulphur, 1 lb. stone lime, and 5 gallons of water. After weighing the lime into a barrel, add 5 pints of water, sift in the sulphur, and slake the lime slowly. Add more water gradually and stir every now and again; when fully slaked cool by adding the remaining water.

PEACH SHOOTS DISEASED: *S. B.* The shoot you send us is attacked by the silver-leaf disease (*Stereum purpureum*). All affected branches

should be cut back, taking care to cut beyond the last discoloured wood; but if the trees are badly affected this treatment may not be found successful. A good deal of mystery surrounds the origin and cure of silver-leaf; some growers think it may be due to an over-dressing of farmyard manure; others, that it follows a particularly wet season. Sulphate of iron has been tried as a remedy as follows:—1 lb. of the crystals were dissolved overnight in water, and the next day sufficient water was added to fill a forty-gallon barrel. This preparation was applied to the roots of the tree, which were afterwards mulched with a thick layer of farmyard manure. The treatment was once repeated; and before the tree was started into growth the following season the worst affected branches were removed. During this second summer the treatment was applied about three times, with the result that a marked decrease in the disease was noticed, and the growth was much more robust. During the third season a slight silvering of the first leaves was noticed, but disappeared as the roots became active, giving place to perfectly healthy growth. The tree furnished a good crop of fruit. It will be seen that the treatment with iron, even when successful, is slow; and unless the utmost care is taken, the tree will contaminate those near it during the process of recovery.

PEAR FRUIT AND FOLIAGE INJURED: *W. F. G.* The trouble is due to the Pear-gall mite. The injured leaves should be gathered and burned, and the trees sprayed next winter with the preparation known as "self-boiled sulphur wash." (See also "Peach Leaves.")

PEAR SHOOTS DYING: *J. H. P.* The trouble is not due to disease that can be attributed to any fungus or insect pest, but has been brought about by unsuitable cultural conditions. If the tree is worth saving we advise you to make an examination of the roots next autumn and remove some of the soil, adding some fresh, rich compost.

ROSE TREE UNHEALTHY: *Tristram.* Stems of old Rose trees often form corky outgrowths such as are found on the specimen you sent. This is not due to disease, and there are no known means of preventing the affection.

SHALLOTS: *E. P. D.* The bulbs are infested by *Sclerotium* disease, caused by a fungus. The soil in which the crop was grown will be infested, and should be treated with lime, as many other kinds of plants are liable to be attacked by this complaint.

SPECIFIC FOR ROSE MILDEW: *Rosa.* As you do not wish to employ flowers of sulphur, on account of the unsightly effect it gives to the foliage, you should use liver of sulphur, at a strength of 1 oz. in four gallons of water. This preparation will not injure the flower-buds, but if the spray touches white-painted woodwork it will turn it black.

TULIPS DISEASED: *W. H. S. and Sons.* The bulbs are attacked by the well-known "Lily-disease," a species of *Botrytis*. The bulbs should be destroyed by burning, but if you wish to preserve them for planting again take the precaution to dust them with quicklime and sulphur in equal parts before they are stored.

TULIPS NOT FLOWERING: *T. C.* See reply to *W. H. S. and Sons.*

VINE LEAVES WITH WARTY EXCRESCENCES: *T. B.* The trouble is due to keeping the vinery too close and moist. Ventilate the vinery and keep the atmosphere less moist.

Communications Received.—*W. S.*—*Inchicore.* [Correspondents must observe the rule to furnish their names and addresses, although these are not published when a request is sent to that effect].—*E. M.*—*R. M.*—*R. A.*, Framlingham—*G. H. B.*—*E. W. H.*—*Geo. T.*, Versailles—*E. N.*—*A. P.*—*A. G.*—*S. V.*—*S.*—*Mr. P. V. S.*—*A. E. T.*—*C. T.*—*H. B.*—*J. B. F.*—*G. H. C.*, India—*J. R. J.*—*G. M. Tayler*, Edinburgh—*W. C.*—*H. S. T.*—*H.*—*Sir H. V.*—*R. Holmes*—*H. C. E.*—*W. G.*—*Professor Balfour*—*T. Mawson*—*Reg. Farrer*, Shensu, China—*Miss T.*

ABNORMAL BLUEBELL: *J. B.* The bracts are virescent, this departure from the normal being not uncommon.

ABNORMAL GLOXINIA: *G. S.* A Gloxinia flower with four limbs to the corolla instead of the normal five is not unusual. Reduction or increase in the number of petals of cultivated flowers is a common occurrence, due, probably, to the altered conditions under which the plants are grown.

AQUILEGIA: *Mayview.* You would find it advantageous, when cultivating your bed for Aquilegias, to always dig the ground a little deeper than on the previous occasion, bringing the deepest soil to the surface. The Aquilegia lives for many years on the same spot without particular attention, but, as you remark, the best results are obtained from seedlings of the first flowering. That is usual with many plants. Cow manure, if you wish to supplement it with artificial, should have a stimulating one, such as slight dressings of two parts nitrate of soda to one part superphosphate of lime; but you might try, in the first place, two or three applications of soot, and if the soil inclines to clay, then add lime. The strain you grow was selected by a Scotch lady of the Borders, and is one of the best.

CATERPILLARS INFESTING APPLE TREES: *S. B.* The examples received are caterpillars of the winter moth, *Cheimatobia brumata*. Spray the infested trees with Swift's arsenate of lead paste according to directions supplied. It is rather late in the season for spraying, but there is, so far as we know, no other remedy.

GOLDFISH: *C. B.* The common goldfish, frequently called Italian goldfish, breed freely in Italy in warm water. The Spanish cold-water goldfish breed in English water. The goldfish is a small species of carp.

GOOSEBERRIES DISEASED: *Anxious.* The symptoms suggest that the bushes are attacked at the collar or low down in the main branches by the fungus *Botrytis*. Plants which are affected cannot be cured, but you should take the precaution of dusting the stems of bushes which are still healthy with quicklime while the bark is damp.

HYACINTH WITH SIX SPIKES: *A. G.* Your plant of Hyacinth with six spikes is not a record, for in *Gard. Chron.*, March 2, 1912, p. 142, a correspondent gives details of a plant in his

THE SOURCE OF YELLOW ROSES.

THE attempt to secure by hybridisation a Rose of clear deep yellow colouring is maintained with undiminished ardour by Rosarians, both amateur and professional, and from the inquiries that are from time to time addressed to me as to the subjects to which recourse may be had, it is evident that considerable uncertainty still prevails as to the characters of the wild or spontaneous yellow species.

It seems worth trying to collect what we know about them in case it may be possible in any way to simplify the task of the hybridist.

Two yellow Roses were known to Parkinson. He calls them *Rosa lutea simplex* and *Rosa lutea multiplex sive flore pleno*. "The first," he says, "is planted rather for variety than any other good use. It often groweth to a good height, his stem being great and woody, with few or no prickles upon the old wood, but with a number of small prickles like hairs, thick set upon the younger branches of a dark colour somewhat reddish, the bark of the young shoots being of a sad greene reddish colour; the leaves of this Rose bush are smaller, rounder pointed, of a paler greene colour, yet finely snipt about the edges, and more in number, that is, seven or nine on a stalk or ribbe than in any other garden kinde, except the double of the same kinde that followeth next; the flower is a small single Rose, consisting of five leaves not so large as the single Spanish Muske Rose, but somewhat

bigger than the Eglantine or Sweete Briar Rose, of a fine pale yellow colour." This seems an admirable description of our modern *R. hispida*, the peculiarity of which is that though in habit and foliage it bears a strong resemblance to the taller-growing members of the *R. pimpinellifolia* group, it is abundantly supplied with setae, but has no thorns. Setae are almost always deciduous.

Parkinson's double yellow Rose must have been our *R. sulphurea* Ait., also often called *R. hemisphaerica* Herm., and, from the account of his experience, it cannot have been much easier to induce this Rose to flower well in those days than it is at the present time. Lindley wrote of it, "This, by far the most splendid of the genus, has never been heard of in a single state, nor even near it, and its native country is still unknown." Its true habitat was probably decided by M. de Tehihatcheff, who discovered it or its spontaneous form *R. Rapinii* Boiss., in Galatia, in 1849. *R. Rapinii* was first collected by Balinsa, and under that name created by Boissier, who at first regarded it as a distinct species, but later considered it as the type or spontaneous form of *R. sulphurea* Ait., a view which Prof. Crépin seems to have adopted (see *Primitia*, pp. 216 and 277), and he does not in his later writings distinguish it from *R. sulphurea* Ait.* *R. Bungeana*, described by Buhse, is merely a form of *R. Rapinii* or *sulphurea*, and *R. caesarea*, another variation, differs in being more glandular. Neither this nor *R. Rapinii* need detain us longer, unless, as some prefer, *R. Rapinii* Boiss. be retained as a name for the single form, and *R. sulphurea* Ait. confined to the double-flowered plant.

R. xanthina is one of the most beautiful of the yellow Roses. It was first described by Lindley, apparently from a picture, as "A Rose with all the appearance of *R. spinosissima*, except in having no setae and double flowers the colour of *R. sulphurea*." Except for the double flowers, which is a form I have never seen, and may perhaps be a mistake of the artist, the above cited words well describe this plant. Its absence of setae and the appearance of its straight thorns and general habit resembling the taller *spinosissima* render this Rose difficult to confuse with any other species. *R. Ecae*, an Afghan Rose, is perhaps rather similar in some respects, but the habit is dwarfer, and though it will live in this country, seldom seems to flower, while *R. xanthina* flowers grandly for something less than a fortnight during May. *R. spinosissima lutea* is another Rose of the *spinosissima* group, and is of a fine yellow colour. It appears to be the Rose discussed by Prof. Crépin in his *Rosae Hybridae*, wherein he concludes that it is probably the result of a cross *R. lutea* × *pimpinellifolia*. *R. lutescens* was described by Lindley as "with branches defended by innumerable slender, unequal, pale brown, deflexed prickles, and an almost equal number of setae"; he

adds, "The flowering shoots offer an excellent discriminative character, as they differ entirely from the branches in their arms, which are little more than tubercles tipped with a weak bristle." Both in habit and colour of the flower this Rose seems to differ from *R. hispida* but little, and that only in the presence of prickles on the stems, and if, as Crépin thought, it and *R. ochroleuca* Gw. be merely hybrids of *R. pimpinellifolia*, it is quite likely that these characters may merge into one another in different individuals. Though I have not seen Gwimpel's authentic specimen of *R. ochroleuca*, the plant sent me under that name, and now in my possession, bears very marked resemblance to *R. xanthina*, especially in the leaves and thorns, and is doubtless a hybrid of this Rose.

The beautiful and early-flowering *R. Hugonis*, though its position may not yet be finally settled, is clearly connected with the *pimpinellifolia* group, and is probably also of hybrid origin.

Rosa lutea Mill. has long been known. It is described by Lindley as "a naked-looking bush about 4 feet high. Branches somewhat erect, dark brown, defended by pale, straight, nearly equal scattered prickles, and no setae; root shoots more densely armed. Leaves somewhat shining deep green; stipules narrow, dilated, and divaricated at the end, finely toothed and fringed with glands a little pubescent or not, petioles naked or downy rarely glandular, leaflets 5-7, elliptical or ovate, a little pointed, spoon-shaped, simply or doubly serrated, naked above, more or less glandular beneath. Flowers deep yellow, large, cup-shaped, solitary; bractae none; peduncle and tube of the calyx unarmed, the latter ovate, sepals ovate, pointed, a little divided, setigerous and even prickly on the outside, petals obovate; disc thickened; styles villos distinct, fruit unknown." He continues: "This has been strangely confounded by some botanists with *R. sulphurea*. And yet their resemblance chiefly consists in the similarity of colour in their flowers, *sulphurea* being undoubtedly allied to *R. sibirica* (one of the *pimpinellifolia* variations), *lutescens*, etc. And this, though very different, so closely bordering upon *R. rubiginosa* that Linnaeus at one time did not distinguish them, and united them under the name of *eglanteria*. . . . It [i.e. *R. lutea*] is known at first sight by its branches with foliage only at the extremities, prickles, usually several under the stipulae, and the leaflets, which are hollow, like the bowl of a spoon." For habitat he gives Austria and the South of France, a habitat which has since been extended to include Armenia and the Western Himalayas.

Lindley, however, was far from settling the positions of *R. lutea* and *R. sulphurea*. Many authors since him have asked whether they may not be two varieties of the same specific type, Crépin himself once raised the question. He points out that both Roses show many features of specific resemblance, have almost the same coloured flowers and an almost identical morphological organisation, while the leaves with their stipules have also a

* Déséglise took the same view and gave his reasons at length in a paper in the *Journal of Botany* (Cult. Russ.), p. 235-6.

great resemblance. In 1889, in reviewing the work of M. Paul Sinten in Armenia, he went fully into the differences between *R. lutea* and *R. sulphurea*. One of the most important is the armature of their stems, the thorns in *R. sulphurea* being normally of the hooked type, while those of *R. lutea* are of the straight type. But properly to appreciate this character the thorns of *R. sulphurea* must be studied as a whole, for it may often happen that in places on the plant the thorns may be more or less straight, and in some variations many may be so. In *R. lutea* the thorns are always straight, though sometimes the point (which is straight) may be turned downwards.

Another distinction is that the epidermis of the stems and branches of *R. sulphurea* is generally charged with glands, a condition that does not occur in *R. lutea*. A third is found in the leaves, which, though much alike, are not the same, being more attenuated at the base in *R. sulphurea*, while in *R. lutea* the teeth are deeper, and they are often finely pubescent. In *R. sulphurea* the stipules and auricles are

xanthina. Before leaving this part of the subject it may be interesting to inquire how far the recognised descriptions of *R. Rapinii* Boiss. carry out Crépin's view put forward above. The best description of this Rose known to me is that of Regel; it is shorter than Boissier's original description, but gives the essential features, and is as follows:—"Branches with strongly-curved prickles dilated at the base, otherwise glabrous, flowering branchlets clothed with setaceous prickles and glands on short stalks. Stipules adnate, leaflets non-glandular beneath, lobes of the calyx entire or with a few short lateral lobules. A tall bush, the stipules expanded, glandular on the edge, petioles and rachis shortly pubescent, nearly unarmed. Leaflets 5-7, obovate, obtuse or shortly-pointed, glabrous above, with a pale, rather soft and very fine pubescence beneath, somewhat doubly toothed. The peduncles glabrous or glandular. Calyx tube glabrous. Calyx lobes lanceolate, acuminate pubescent on both margins. Petals yellow, crowned by the calyx lobes."

FIG. 150.—CATTLEYA TRIANAE AS GROWN IN CANADA.

less dilated and their edges less toothed than in *R. lutea*.

The inflorescence in *R. sulphurea* is always single-flowered, and the peduncles are shorter, the receptacles smaller, and the sepals shorter. In *R. lutea* the inflorescence is rather often many-flowered.

Finally *R. sulphurea* fruits regularly, and its receptacles ripen and produce well-developed seeds, while in *R. lutea* the receptacles, according to Prof. Crépin, always remain absolutely sterile. He says that in his experience he had never seen really fruiting receptacles of this species. At most the fruits contain atrophied achenes. In like manner *sulphurea* possesses well-developed pollen, while in *R. lutea* a very large proportion is imperfectly developed. Crépin found only one-fifteenth of the pollen perfect in this Rose, though a correspondent had a higher proportion. Not unnaturally, he asks "Does this point to *R. lutea* itself being a hybrid?" If so, he thinks *R. sulphurea* must be one ascendant, while the other may be either *R. pimpinellifolia* or perhaps Lindley's *R.*

This description agrees fairly well with Lindley's *R. sulphurea*: the chief discrepancies are that Lindley says that the leaflets of the double form he is describing are free from pubescence in every part, but very caesious beneath, and simply-toothed, while Regel's account of *R. Rapinii* gives the leaflets as having a very fine pubescence beneath and somewhat double-toothed (sub-biserate). These differences in such a variable organ as the leaf do not seem sufficient to displace Prof. Crépin's view, confirmed as it is by Déséglise that *R. Rapinii* is the spontaneous or wild form of *R. sulphurea*.

We are thus driven to the conclusion that the yellow species free from hybridity to which the hybridiser may have recourse do not exceed three, namely, *R. sulphurea* (including *R. Rapinii*), *R. xanthina* and *R. lutea*—a conclusion arrived at by Prof. Crépin in his *Rosae Hybridae*; while if, as seems extremely probable, *R. lutea* be itself a hybrid, there may be only the two first named.

There are two garden forms which may receive notice for their good yellow colouring.

Persian Yellow was introduced into this country from Persia in 1833 by Sir Henry Willock, and into France in 1842 (see Jamain and Forney; the date given in the *Noms des Roses* is 1837). It is a fine deep yellow, particularly when grown under glass.

The other Rose is *Harrisonii*, said to have been raised from seed in America, and sent out by Mr. Harrison in 1830. It is of a somewhat lighter or canary yellow, and has much of the habit of the *pimpinellifolia* group. *White Rose*.

ORCHID NOTES AND CLEANINGS.

CATTLEYA TRIANAE.

THE accompanying illustration (fig. 150) is from a photograph sent us by Mr. W. J. Jones, Orchid-grower, Dale Estate, Ontario, who is largely engaged in growing Orchids for cut-flowers. The specimen is of exceptional merit, bearing eight flowers on one spike and six on each of the other two. Mr. Jones says:—"I may say that four, five, and six flowers on a spike are quite common with us, but eight is an extraordinary number. *Cattleya Trianae* is one of our best commercial varieties, for we have cut over 15,000 flowers since the beginning of last November to the end of March. We are now cutting (April 6) from a large batch of *Cattleya Schröderae*, and for the Easter trade alone we shall cut from 5,000 to 6,000 flowers." *Cattleya Trianae* is one of the most variable and widely distributed of the labiata section; the plants from some localities are superior in the size and beauty of their flower to those from other districts, and the Popagan forms are the best. It was collected by Wier for the Horticultural Society in 1863, and it was awarded the R.H.S. First-class Certificate on February 20, 1866. From that time until the early seventies some fine forms were certificated to Mr. Marshall, for many years Chairman of the Floral Committee, and since then forty distinct varieties have received awards, mostly in the months of February and March.

It was always a favourite Orchid with British growers, but two things have brought a decrease in the numbers grown of late. Being a winter flowerer, it is not so well adapted for growing in the neighbourhood of towns and in manufacturing districts, where fogs often prevail at that season, and destroy the flowers before they can expand, as cause them to develop imperfectly. Another cause of decadence is that since the advent of hybrid Orchids less space in the Orchid houses is given to imported species.

Nevertheless, for market purposes in good localities the grower in England might find the more extended culture of large-flowered *Cattleyas* to be as profitable here as it appears to be in Canada.

TREES AND SHRUBS.

NEW CHINESE SPECIES.

In the following list of trees and shrubs, introduced into this country from China, I propose mentioning only those which are cultivated with success here at Aldenham. It may be of interest to those who wish to make trial of them if I mention that our conditions are by no means favourable. The soil is a cold, stiff clay, and most of the plants suffer considerably from early spring and late autumn frosts. It may safely be said, therefore, that any importations which survive here are likely to do well in almost any part of this country.

Most of the seven hundred specimens grown here by the Hon. Vicary Gibbs were raised from seed sent home by Wilson. Some of the trees are already upwards of 20 feet high, and promise to make first-rate

specimens; but the heights given in the list are of those mentioned by Wilson as growing in a wild condition. It is probable that under careful cultivation many would attain to a much greater size.

TREES.

ACER DAVIDII (20 feet-30 feet) is a beautiful little tree. The bark is striped with white, which gives the stem a bizarre appearance, which is attractive when the leaves have fallen.

ACER HENRYI (35 feet) is a deciduous tree. The young leaves, on first opening, are of a delicate pink, changing slowly to a rich green.

ACER LAEVIGATUM is evergreen. It is doubtful whether this *Acer* is really hardy, which is a pity, as it is decidedly one of the most attractive. The long, narrow leaves measure from 6 inches to 7½ inches; their bright, delicate tints becoming on maturity exceedingly effective. The plant is well worth a little coddling.

ALANTHUS VILMORINIANA (150 feet) is distinguished from *A. glandulosa* by its spiny stems and long leaves. It is a handsome, typically-tropical plant; the leaves, which are from 3 feet to 4 feet long, are borne on red petioles.

ALNUS LANATA is a strongly-growing Alder, but it may not prove quite hardy, especially in severe winters. Nevertheless, it has done well here so far, and is certainly an acquisition to the *Alnus* family.

ALNUS CREMASTOGYNE is hardier than *A. lanata*. It has rather small, bright green leaves, and branches very freely; it would make an excellent water-side plant.

BETULA No. 900 is described by Wilson as the best Birch in China. It has small foliage and rather wiry branches; its chief beauty lies in the bright, orange-coloured bark which is exposed when the outer, older bark peels off. Our specimens are too young as yet to show the fine colours described by Wilson, but there are already indications of success.

CATALPA FARGESII (20 feet) is a small tree, with large, pale-green leaves. Our specimen has not yet flowered, but the foliage is very attractive.

CERCIS RACEMOSA grows well, forming a small tree, but with leaves larger than those of *C. Siliquastrum*. It is said to bear rosy-red flowers.

CERCIS CHINENSIS bears magnificent foliage, but is, unfortunately, not sufficiently hardy for general use.

EUPTLEA FRANCHETII forms a small specimen, with red stems and petioles. The leaves have a wrinkled surface. The tree branches thickly and neatly, and has an ornamental appearance—especially in autumn, when the foliage assumes very attractive colours.

JUGLANS CATHAYENSIS is a large tree, bearing pinnate leaves 2 feet to 3 feet long. The male catkins are 12 inches to 15 inches in length; the plant is a vigorous grower, and makes a good specimen for isolated positions. It has already borne fruit, which is black in colour, and has ripened seed, from which we have obtained several young plants.

LIRIODENDRON CHINENSIS (50 feet), the Chinese "Tulip Tree," bears much larger, handsomer foliage than the American species, *L. tulipifera*. It is certainly a beautiful tree, and assumes in the autumn varied and delightful colours.

MORUS No. 10 forms a large bush or small tree. The stems are grey, and the foliage light green, a combination which gives a peculiarly attractive effect. The fruit resembles that of the common Mulberry.

PAULOWNIA TOMENTOSA VAR. *LANATA* is a quickly-growing tree, said to bear flowers of a purplish colour. It has larger leaves than *P. imperialis*, and bears them for a longer period. It is also somewhat hardier, but requires a sheltered position and good soil. It well repays any care which is expended on it.

POPULUS LASIOCARPA (70 feet) may be said to be, so far, the best of the *Poplars*. It bears very large leaves, with red petioles and veining. It will grow fairly well in a dry position, but prefers a moist situation.

RHUS HENRYI is a large shrub, or small tree, with long, pinnate leaves, thin in texture, and in colour a light green. It is an attractive plant.

SALIX MAGNIFICA is a beautiful Willow, of quick growth; the leaves attain the size of 10½ inches by 6½ inches. Both leaves and stems are glaucous. It is said to bear catkins of great length, but none have as yet appeared on our specimen. At the first glance it seems to have little affinity with the *Salix* family, and more nearly resembles a *Magnolia*.

XYLOSMA RACEMOSUM VAR. *PUBESCENS* (60-70 feet) is a pretty evergreen, with small leaves and spiny branches. Wilson describes it as one of the handsomest evergreens in China.

CEDRELA No. 626 is a very fast-growing tree, with pinnate leaves from 2 feet to 2½ feet long.

PRUNUS CONRADINAE belongs to the *Cerasus* section of the *Prunus* family. It forms a graceful specimen, with rather thin shoots and large leaves. It bears pink blossoms, which add fresh beauty to its appearance.

PRUNUS PILOSIUSCULA VAR. *MEDIA* is a freely flowering Cherry. The flowers, which are pink, are borne in early spring.

EVODIA No. 387 (20 feet) forms a small tree, with red-brown stems and pale green leaves.

LIQUIDAMBAR FORMOSANA VAR. *MONTICOLA* (50 feet) is a fine variety for autumn effect, assuming a brilliant red in that season. The foliage is carried well on into the winter, and the variety is a good deal hardier than the species.

TETRACENTRON SINENSE is a distinct and beautiful species, bearing delicate stems, long pointed buds, and broadly ovate leaves. The foliage is at first a pleasing shade of bronzed-red, changing to green on maturity. The specimen will probably attain to the dimensions of a small tree.

RHUS No. 123 is an ornamental tree with large, pinnate leaves. If the present rate of growth (3 feet to 4 feet in a season) is maintained, it will form a tree of considerable dimensions in a few years.

SHRUBS.

BERBERIS SARGENTIANA is an evergreen Barberry with large, tough leaves 3 inches to 4 inches long, and formidable spines. Part of the foliage becomes bright scarlet in the autumn. The leaves resemble those of *B. Knightii* in shape, but the size is larger. The flowers, which measure about half an inch in diameter, are almost white, and are followed by black fruits. The species is considered to be the hardiest of all the evergreen Barberries, and is a fine and attractive addition to the family.

BERBERIS SUBCAULIALATA (4 feet) is a semi-evergreen species, which flowers late in the summer. It forms a dense bush, and makes an attractive specimen, especially in November and December, when it is bearing its bright, scarlet berries.

BERBERIS AGGREGATA is a deciduous species, resembling *B. Wilsonae*, but more pyramidal in form. The berries are coral-red, and rather large.

BERBERIS WILSONAE has already established itself in the public favour, and it is certainly a very attractive plant, with its delicate stems, small, glaucous leaves, and salmon-pink berries. It is a good plant for rock-gardens.

BERBERIS GAGNEPAINII is a compactly-growing, pretty evergreen, with narrow, twisted leaves, of a bright green colour. It is likely to become a general favourite.

CORIARIA No. 12 grows strongly, the stems attaining to a length of 6 feet to 8 feet. The catkins, which open in spring, are red; the fruits are said to be black, but it has not fruited here up to the present.

DEUTZIA VEITCHII flowers very freely, and at an early stage. The blossoms are pink, and the plant is considered one of the best *Deutzias* of this colour in cultivation.

DEUTZIA LONGIFOLIA resembles *D. Veitchii*, but the flowers are not so large, nor the colour so bright.

EUONYMUS JAPONICA VAR. *ACUTA* is an evergreen climbing or creeping shrub, with small leaves, veined with white. It would be suitable for hanging over rocks.

CORNUS PAUCINERVIS is a low, spreading shrub, with narrow leaves and white flowers. The stems are bright green, which gives the plant an attractive appearance in winter. It is suitable for rock-work, or for growing under trees.

COTONEASTER DAMMERI is a creeping, evergreen species, which grows quickly. It forms an excellent groundwork for shrubs of upright habit. The flowers are white in colour and the berries are red.

COTONEASTER DAMMERI VAR. *RADICANS* has broader leaves than the species, and does not spread so fast. It is a very suitable plant for a rockery.

COTONEASTER HORIZONTALIS VAR. *PERPUSILLA* is an attractive, closely-growing form of *C. horizontalis*. It bears bright red berries, which show to great advantage when the leaves have fallen.

COTONEASTER DIVARICATA forms stout, freely-branching stems, and grows to a height of 4 feet to 6 feet. The flowers are pale pink, and the fruit red, very freely borne. It is perhaps at its best in autumn, on account of its wealth of berries.

COTONEASTER SALICIFOLIA VAR. *RUGOSA* is a handsome evergreen of upright habit. It bears white flowers, followed by scarlet fruits, which are produced in great abundance.

COTONEASTER SALICIFOLIA VAR. *FLOCCOSA* has narrower leaves and smaller fruits than *C. s. var. rugosa*. It is altogether a more elegant plant, and would look well where *rugosa* might be too large.

COTONEASTER ZABELII is a good deciduous species. Pink flowers are followed by dark red berries, very freely borne, which render it a conspicuous object when the leaves have fallen. *E. Beckett, Aldenham House Gardens, Herts.*

FOREIGN CORRESPONDENCE.

ERRONEOUS NOMENCLATURE.

THE difficulties attendant on the correct labelling of plants increase every day. To lovers of plants, who collect them *con amore*, it is quite depressing to read certain catalogues. For instance, in a list of Alpines or perennials the name of an apparently new plant is found; but if the plant be ordered, it proves to be an old friend under a wrong name. Some catalogues give the same plant under two, three, and even four different names, so that the fervent collector (unless he be a skilled botanist) may get the same plant several times over.

The difficulty caused by these wrong names, however, sinks into insignificance beside the confusion produced by the naming of plants by titles which are non-existent, or are the result of a lapsus made by some ignorant person in the copying of a label. Take, for instance, the barbarous word *Pintenectitia*, which clung for twenty years to *recurvata*. I remember, when I was a boy, Mr. van Houtte relating that one of his gardeners, in copying a label which bore the name of "P. C. Noline" (to whom the genus *Nolina* was dedicated by Michaud), miswrote it "Pintenectitia." Thus the absurd name passed into the nurseries, creating ever-fresh difficulties among cultivators, until one in despair made of it "le pot aux Roses."

A similar error seems to have been the origin of the famous blunder "*Sempervivum californicum*," which prevails all over Europe. The

name is probably a corruption of *S. calcareum*, Jordan, which plant grows in the centre and south-east of France: I found it gracefully adorning the ruins of the old Temple Church near Comps, in the Var. Everyone knows that neither in California nor in any part of America is there a *Sempervivum* to be found, the genus being essentially European.

ing surprise that he should have thought it an Alpine. In reply he sent me a small catalogue (compiled by a small nurseryman) in which "*Urvillea acaulis*" figured as an Alpine. Curious to see what it could be I obtained a plant, and found it none other than the familiar *Centaurea Urvillei*, a small perennial and not very ornamental, but useful in a collection.

year I was visited at Floraire by a nurseryman who lives near London. I was not at home at the time, but when I returned my head gardener reported that the visitor had told him the plants of *Daphne collina* were wrongly named: they should be called *D. Fronina*. Now, I have constantly laboured (but apparently in vain) to prove that there is no "*Daphne Fronina*" at all; the name is a stupid corruption of *D. collina*, and no book on botany, or index, or catalogue of any note recognises it. Yet the gardener who took exception to the name *D. collina* is quite a clever grower who exhibits successfully in flower shows.

Another error which occurred a short time ago was in the name of an *Achillea* of which photographs appeared in the horticultural papers. The plant was called "*Achillea argentea*," but should have been "*A. argenti-folia*," *A. argentea* being a synonym either of *Pyrethrum argenteum* or of *Achillea Clarence*.

I once obtained a small branch of an *Erodium* which was sent me from a famous garden where it was grown as an importation direct from the Orient. The plant was labelled under some absurd name which I have now forgotten; the owner of the garden was dead, and the gardener, in renewing the labels, had also renewed the name. I took the plant with me into the library, shut the door, and, with the aid of Edmond Boissier's *Flora Orientalis*, decided that it was the famous *Erodium Guicciardii*, of Heldreich, from Aetolia, Orient, of the utmost rarity in gardens. I asked, therefore, for cuttings, and soon had the plant flourishing at Floraire under its right name.

I should like to mention the great esteem I have for those nurseries—and I must acknowledge that in England they are in the majority—in which the real names of the plants are carefully preserved. In the Swiss Exhibition held at Geneva in 1896 a special prize was awarded to those exhibitors whose nomenclature was above reproach. I do not know whether this principle is adopted in English shows, but I hope that the R.H.S. will take care in every way to impress upon its members the importance of the question of nomenclature, upon which order and clearness in the domain of horticulture so greatly depend. *H. Correvois, Geneva.*

THE MOON'S EFFECT ON PLANTS

IN reference to the correspondence on this subject (see p. 151), let me say that in Holland every farmer and every journeyman will tell you that the moon has an influence on plants. It would be interesting to know whether the same belief exists in other countries. If there really be an influence by the moon on plant growth, it would be also very interesting to know on what this influence depends. Here I have heard nothing about it from the natives. *M. Buysman, Jardin Botanique, Lawang, Java.*

HYBRID ARABIS.

M. CAYEUX has obtained interesting results by crossing *A. alpina grandiflora superba*, a vigorous race with pure white flowers, and *A. alpina rosea*, a less robust race, the flowers of which are bright rose-coloured, but small.

The individuals resulting from the cross exhibit the vigour of the former race, and possess rose-coloured flowers of a less bright tint than in *A. rosea*.

In the second generation a large amount of segregation was observed, and the individuals showed a considerable range of form, habit, foliage, size and colour.

A very charming plant of the F_1 generation named *Arabis alpina rosea grandiflora*, possessing the vigour of the large-flowered mother plant, and also delicate rose-coloured flowers, was propagated by division, and received from the National Horticultural Society of France a Certificate of Merit. *A. M.*

[Photograph by C. P. Raffill.]

FIG. 151.—*PRUNUS SARGENTII*: FLOWERS PALE ROSE COLOUR.

(See p. 347.)

I was asked a short time ago by an English visitor to Floraire for a plant of "*Urvillea acaulis*." Never having heard of this plant, I took my *Index Kewensis* and found that *Urvillea* is a genus in N. O. Sapindaceae. I wrote to my visitor giving him a description of the plant he had asked for, express-

However, it is not everyone who has the time or the patience to search out the right name in such cases, and I know many collectors who have been seriously discouraged by these and similar mistakes in nomenclature. It is a great pity that nurserymen are not more careful to avoid adding to the number of errors. Last

PRUNUS SARGENTII.

THIS beautiful Cherry appears to have been introduced to cultivation first by Dr. Bigelow, who, in 1890, collected seeds in Japan and sent them to the Arnold Arboretum. Two years later Professor C. S. Sargent collected seeds in the same country, and in 1893 the species was introduced to Kew. For some time it was thought to be the type of *Prunus Pseudo-cerasus*, but in 1908 was proved to be distinct, and was given the above name by Mr. A. Rehder. It is a deciduous tree, said to reach a height of 80 feet in Japan, with a trunk 9 to 10 feet in girth. Its leaves are between oblong and obovate, the largest 4 inches long and 2 inches wide, rather abruptly narrowed at the apex to a slender acuminate point, and sharply toothed. The flowers are of a pale rose colour, and about $1\frac{1}{2}$ inch wide, the petals notched at the end; they are borne in clusters, two to five together, each flower with a stalk up to $1\frac{1}{2}$ inch long. It blossoms in great profusion in April, as may be seen from the illustration in fig. 151. The Cherries are small and shining black, about $\frac{1}{2}$ inch wide, but are not very freely borne in this country. I remember seeing the originally introduced trees in the Arnold Arboretum in July, 1910. They were then 25 to 30 feet high, and laden with an extraordinary profusion of black Cherries, which gave the trees a striking and handsome appearance. As a timber tree this is perhaps the finest of all Cherries; it is also one of the most ornamental. H. J. B.

NOTICES OF BOOKS.

LES ILES D'HYÈRES.*

IN the *Gardeners' Chronicle* for October 8, 1908, appeared a long notice by the present writer of a book on the Flora of the Var by the late Abel Albert and M. Emile Jahandiez, which was printed, like the present work, at the private press of the two brothers Jahandiez at Carqueiranne.

The beautifully illustrated volume before me, on *Les Iles d'Hyères*, is much more interesting, for it is an account of the general history, geology, flora and fauna of those remarkable Mediterranean islands, the Stoechades of the ancient Greeks, lying south of Hyères, a few miles from the mainland of the Department of the Var. The old name of these picturesque islands is familiar in *Lavandula Stoechas* and *Helichrysum Stoechas*, so well known to visitors on the Riviera.

The author of this useful book is M. Emile Jahandiez, a travelled botanist and naturalist. The illustrations comprise five maps, thirty-six fine plates, and thirty-two smaller figures from photographs, drawings, and paintings by the clever artist, M. Albert Jahandiez. It was my privilege, after several previous visits, to spend a couple of days in May, 1913, on the Isle of Porquerolles with these remarkably able and versatile brothers, when some of the most interesting photographs were taken. Porquerolles is the largest of these islands, which are also called Les Iles d'Or. It is the most accessible (from Toulon or Hyères) and the most populated. But, unfortunately, since a recent change of ownership, opportunities for studying its natural history have not been improved. For example, the only two stations in France for the handsome *Lathyrus tingitanus*, which had long been naturalised at Porquerolles, have been destroyed.

The islands, barely 3,000 hectares in area, support flora remarkable chiefly on account of several almost endemic species, and because it forms a link between that of Corsica and the Provençal mainland. Of twenty-eight very rare French species which occur twenty-six are strictly

Mediterranean, and most of them here attain their northern limit; twenty are fairly distributed in Corsica, and four species—*Delphinium Requiinii*, *Cirsium trispinosum* (a remarkable Thistle), *Teucrium Marum* and *T. massiliense*—do not appear on the adjoining mainland, and may be survivors of an earlier geological period. The points of connection with the Spanish flora are more numerous than with that of Italy, twelve species are characteristic of the islands of the western Mediterranean, and five appear in the Isle of Ste. Marguerite, near Cannes.

About 73 pages are devoted to a complete list, with localities, of the Phanerogams, and 36 pages are given to lists of the mosses, algae and fungi. A good majority of the 200 fungi is described as edible. How characteristic of France!

Then follows a chapter on the zoology, with lists of all the known mammals, reptiles, birds, fishes, molluscs and insects. The short list of twenty-three butterflies is, however, certainly incomplete. The remarkable promontory, known as the Presqu'île de Gieus, and the sands and salt marshes of the connecting isthmus, are described in this work, which is really a greatly enlarged, rewritten, and cheaper edition of one which the authors published some ten years ago. There is a short introduction by M. C. Richet. H. S. Thompson.

THE LAND.*

THIS is a breezy book, written by a man who thinks for himself and who is not bothered overmuch with conventional science. The object of the author is to create "a fresh interest in the land, to promote a healthy co-operation between town and country, and to restore the land to its former position as a sound investment . . . to make it once again what it ought to be, viz., the nation's premier gilt-edged security."

The text of the author's discourse is that the land, fully cultivated, will prove a veritable gold mine lying within 12 inches of the surface. The present failure to exploit this El Dorado is to be ascribed to lack of labour, to which cause the author attributes the fact—as he claims it to be—that 90 per cent. of the agricultural land of England is imperfectly farmed.

To reform cultivation labour and improved machinery must be available, and the farmer must put in practice the teachings of Jethro Tull, the Berkshire husbandman of 200 years ago. The author's tribute to the genius of Tull is a fine one and deserves to be widely read. Tull was indeed a wonderful man, for he had the genius to draw absolutely right conclusions from absolutely wrong premises. Plant nutrition, according to Tull, is a simple business. The roots of plants are like intestines. Food must be got into them. The food which they want consists of particles of soil. In order to be got into the intestines (the roots) the particles must be very small and the roots must be able to squeeze themselves among the soil particles. Therefore the soil cannot be cultivated too thoroughly nor too often. Every one of Tull's postulates is unsound, but the conclusion which he draws is unchallengably right.

Naturally Tull carried his illogical reasoning to illogical conclusions, and maintained that tillage, and tillage alone, will supply plants with all the food they require, and that manure is unnecessary. Nevertheless, it is not to be gainsaid that Tull deserves all the encomiums which our enthusiastic author lavishes upon him.

Having concluded that the finer the soil be divided the larger the yield, he proceeds to develop his ideas of an improved form of machinery which shall enrich the soil, and by pounding it finely enough transmute it, as it were, into gold. "The greatest need of agriculture is the production of an oil-motor that will travel over the land without pressure upon or panning the subsoil." And to the question,

"Will it ever be forthcoming?" the author gives a hopeful answer in his chapter entitled "The Expected Motor-Digging Plough." This apparatus, the coming of which is to herald the agricultural reformation, must work on the rotatory system. The specification of the requirements which it ought to satisfy is set forth with something of the fervour of the prophet; but it is all very well for agriculturists to be told to "Wake up" and "March forward" when the plough which is to lead them into the promised land exists only in the fertile brain of our author.

Succeeding chapters deal with crop rotation and land tenure; the latter, the author thinks, will be on a co-operative basis, with small holdings "near the chimneys and large holdings in the open." In this golden age of agriculture the great holding will pay 15 to 20 per cent., and labour thereon will be the best remunerated in the kingdom.

Indomitable optimism is the keynote of this interesting little work, and although now and again a doubt may arise, the reader, remembering that it is useless to argue with a prophet, will do well to let his doubts alone, and to devote himself to reflection on the many wise and shrewd remarks with which the author points his moral and adorns the tale of how the new agriculture is to be established.

BRITISH PLANTS FROM THE NATURE STUDY POINT OF VIEW.*

ANOTHER contribution to the already long list of books designed to meet the requirements of the nature student, "This little book is intended to give the beginner and the student of Nature Study a brief, but clear, insight into the characteristics of the better known orders of British wild plants."

Since the volume runs into 250 pages of letterpress, illustrated by 72 photographs, the author is perhaps somewhat modest in so describing his work. Of the excellence of the illustrations there can be no doubt. They are photographs of the plants described—many of them in their natural habitats, and are of quite unusual distinction and charm. One may select for special mention those of the Water Buttercup, the Greater Stitchwort, the Cross-leaved Heath, the Primrose, and many of the photographs of trees.

In the main the letterpress consists of a general account of a number of families of plants, with detailed descriptions of some of the British members.

There is not much scope here for originality, and the author is not always as careful as he might be in the use of Latin and common names when the same plant is referred to. On page 118, for instance, alluding to *Adoxa Moschatellina*, he refers twice to the Moschatel, but a few lines below he uses the generic name without giving the beginner any clue that he is referring to the same plant.

Mr. Horwood has collected many of the local names of common British wild plants, and has further loaded his botanical descriptions with odds and ends of information culled from Herbals and books of Folklore.

The botanist will certainly take exception to some of the conclusions set forth in the introductory chapter.

Is the author really prepared to maintain, for instance, that "the division of water plants . . . is connected with the derivation of land plants from water plants, since the latter were the forerunners of the former, though in one case the Green Algae of the fresh water were derived from one or more types of seaweed"? (The italics are mine.) And again, "The trailing land plant is a water plant which has adopted a land existence."

These are statements to the support of which it would be indeed difficult to bring convincing evidence! M. C. R.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

ECHINOCACTUS (LOPHOPHORA) WILLIAMSII (see p. 313).—Any reference to Cacti is so rare in the horticultural papers that the remarks in your issue of the 9th inst. regarding the above plant came as a very pleasant surprise. Lemaire's genus *Anhalonium* (or rather *Aerocarpus* Scheidweiler) is closely related to *Mamillaria*, and sometimes sunk in it. But Dr. Karl Schumann has pointed out that *Echinocactus Williamsii* cannot be referred to this genus as the flowers are areolar and not axillary. The same great authority refused to recognise Coulter's

CHINESE TULIP AND SASSAFRAS TREES.—In your account (May 16, p. 333) of these remarkable trees, the credit of introducing, and not of discovering, them should have been attributed to Mr. Wilson. The Chinese Tulip Tree, *Liriodendron chinense*, was discovered by Shearer and Maries in the Lushan Mountains, near Kiukiang, as long ago as 1875 and 1878; and was subsequently collected by Dr. A. Henry and other botanists in different parts of Central China. The Chinese Sassafras tree was discovered in the mountains of Hupeh by Dr. A. Henry in 1884, and was subsequently found near Ningpo by Dr. Faber. It was originally called *Lindera Tzumu* and *Litsoea laxiflora* by Hemsley in *Index Florae Sinensis*,

stake in the centre for support. What impressed me most, however, was the small size of the pots in which they were grown; the majority were in 6-inch pots, and I noticed none of the pots exceeded 8 inches in diameter. The variety of colours was splendid. On one of the side stages of the same house was an equally well-cultivated batch of *Schizanthus*, Sutton's large-flowered hybrid. I noticed many plants in 60-sized pots from a foot to 18 inches in height and as much in diameter, with flowers of the most charming shades of colour. There are many other things which Mr. Newman grows with equal skill and success. *B. Ashton, Lathom Gardens, Ormskirk.*

THE LESSER NARCISSUS FLY (EUMERUS LUNULATUS).—The note of Mr. Geo. St. Ox (p. 336) is of interest inasmuch as it appears to promise us what so far we lack, namely, some useful information concerning this fly based not on surmise or deduction, but upon actual fact and observation. But first let me reply to his question whether the statements made by me in my note to *The Garden* were not based upon deductive reasoning. My answer is, Certainly not. The note in question was merely a condensed summary of the various "Enemies of the Narcissus," and did not in any way pretend to be an exposition of the various considerations, in detail, which led up to the conclusions stated. But inasmuch as several dozen bulbs when raised were found to contain the *Eumerus* in quantities varying from over 100 (in the case of *Narcissus* *Glory of Noordwijk*) to two or three in other bulbs, the operations of the *Eumerus* larvae were a matter of observation, and not of speculation. As a system I distrust deductive reasoning, although in the hands of genius it has sometimes produced startling results. But, as a rule, I agree with the gifted Arnold Toynbee, who, in his earlier days a conspicuous employer of the method, in his later years emphatically repudiated purely deductive reasoning, as—to use his own words—"too often leading merely to metaphysical subtleties and mazy entities." But to the point of interest to us: Mr. Geo. St. Ox affirms, not as a matter of opinion merely, but definitely and certainly, that admitting what Mr. Bliss appears to doubt, namely, that the two flies, the *Merodon* and the *Eumerus*, are allied in entomological classification, nevertheless that the resemblance ceases there, and—here we have the important statement—that "they are different in general appearance, in habit, and in their life circle." Now, if Mr. St. Ox's assertion is based upon actual and careful observation and experience he is in a position to throw useful light upon at least one aspect of the question. "Appearance" goes for little, but "habit" and the "life circle" go for much. Would it be trespassing too much upon your correspondent's time if he would state, in some sufficient detail, the actual observations and experiences which have led him to feel justified in making the very distinct and definite statements to which I have referred? Contributions to exact science are always most welcome. *Charles E. Shea.*

THE CHELSEA SHOW.

FIG. 152.—TELOPEA SPECIOSISSIMA.
(See Floral Committee's Awards, p. 364.)

genus *Lophophora* as valid. As regards Mr. Holmes's system of cultivation, it is more usual to afford a more nourishing soil to this as well as to other Cacti. Undoubtedly, too, satisfactory growth cannot be obtained without a free supply of water to the roots during the somewhat short growing season, and frequent overhead syringing in hot sunny weather is generally found decidedly beneficial. A minimum temperature of 45° F. in winter is doubtless quite high enough for numerous species; we are probably inclined to grow Cacti far too warm. It is unfortunate that, in this country at least, there is no means by which those who grow Cacti can make known the results of their experience in cultivation and learn that of others. As a family the Cacti are excelled by no other in the beauty of their flowers, and their marvellous forms are of never-failing interest. *R. A. Todd, Fulwell House, Nunney, Frome, Somerset.*

pp. 383, 392 (1891); but was ultimately described by him as *Sassafras Tzumu* in *Kew Bulletin*, 1907, p. 55. Further accounts of both these peculiar trees will be found in Elwes and Henry, *Trees of Great Britain*, Vol. I., p. 64, and Vol. III., p. 515. The credit of their introduction is due to Mr. E. H. Wilson, who sent seeds from Central China to Coombe Wood in 1900 and 1901. *A. H.*

CINERARIAS AND SCHIZANTHUS AT CUERDON HALL GARDENS.—A few days ago, when visiting Mr. Jno. E. Newman at Cuerton Hall Gardens, near Preston, I had the pleasure of seeing the finest cultivated batch of *Cineraria stellata* in my experience. The plants occupied the centre bed of a span-roofed house about 50 feet long, and ranged in height from 18 inches to 4 feet 6 inches, many of them being more than 4 feet in diameter and having only one

ROADSIDE BEAUTY.—I have not seen the letter in the *Times* referred to on p. 300 in your issue of May 2, but you say sufficient to prove how easy it is to condemn the various causes to which you attribute blots on our country roadside beauty. Now, let me take your remarks seriatim. In this part of Hampshire, which is noted for its flora, the plant collector is unheard of, except perhaps the man who digs up a few *Primrose* roots to transfer to districts where there are few naturally. In this district there are acres and acres of *Primroses* in woods and hedgerows, and they increase annually. Now with regard to the smearing of the roads with tar, you say he lays down poison for the trees and shrubs which adjoin the road. I fear you have not inquired into the method in which the tar is used, and also what a boon it is to plants, especially fruit-growers whose land adjoins tarred roads much frequented by motors. First the grit and dust from one half of the road is swept into the middle of the road, the tar is made hot and spread over the swept portion. The dust is then laid evenly over the tar, thoroughly cover-

ing it. If sufficient dust and grit are not available, sand is added. Now, under this method the tar is completely covered, and beyond a slight smell for a few days it is not afterwards noticed. How tar so laid can be a poison to trees and shrubs requires explanation, and the present luxuriance of roadside plants is a proof that they are not injured. Next as to the advantage of the use of tar. Apart from the allaying of the dust to those following a motor, either driving or walking, the tar prevents the wearing of the road surface, therefore on that score alone the tarring is economical. The boon to the fruit-grower is great. Instead of his fruit being smothered with dust for yards into the fields away from the hedge, it now remains comparatively clean. Now I come to the case of the farmer, who is always to blame for something or another. No good farmer ever allows his hedges to grow in a neglectful manner, but he trims them annually, and generally twice in a year, allowing them to grow to stated heights of 4ft., 5ft., or more, as circumstances warrant. Such hedges are not cumberers of the ground, but are absolutely essential to success. Here are hedges of Quick one hundred years old still remaining 4ft. 6in. high and less than one yard wide. Again, we have hedges of the same age 20ft. high. These are not cumberers of the ground, because they are a shelter, but they do not encroach on the land unnecessarily. They are shelters for fruit trees and cattle. Properly kept ditches do not require hedges to guard them, rather the opposite. Arable land would be better without hedges at all, or certainly those only which grow a yard or so high; these are all the better for being closely trimmed annually. The advantage of low hedges is in the case of harvest or haymaking. High hedges or belts of trees hinder the corn drying after being cut: in the same way saves hay from spoiling in that portion of the field. *E. Molyneux, Swanmore Park Estate.*

DOES SPRAYING FOR APPLE-SUCKER PAY?—

In further reference to my remarks on "the forlorn hope of spraying" on page 310, I should be glad if any readers who have been spraying against Apple-suckers will say if they have found any or many dead ones on examining the trusses of blossom after the operation. Since my last notes were written I have examined a great number of trusses two days or more after spraying, and I have found very few dead suckers, certainly not one to ten live ones found. Yet the wash used has killed the great majority of suckers in trusses cut off the trees and dipped in it, presumably all that were thoroughly wetted. Indeed, when I used only 6lb. of soft soap to 100 gallons (1oz. to a gallon), instead of 12lb., twenty-two out of twenty-seven were found dead twenty hours afterwards, and three of the five live ones were in a particularly compact truss. One inference is that all that were well wetted were killed. Another is that in ordinary spraying not one out of ten suckers is thoroughly wetted. Many other tests were made, and the success was much the same when the trusses were dipped in the wash. If it pays at all to spray against suckers before the blossom expands, my conclusion is that it is better to drench the trees with a weak wash than to spray them lightly with a strong one. With soft water 6lb. of good soft soap to 100 gallons, and with hard water 8lb., should suffice. In my opinion the quantity of wash used is of much more importance than the force applied. No amount of force will get the wash down to the axils of the blossom-buds and leaves if the stuff hits a truss on the side, as it does in the great majority of instances. What is wanted is to drench the trees so that the wash will run down into the trusses. I have tried using washing soda, 1oz. to a gallon, with the same quantity of soft soap, and still there was the lack of many dead suckers found on the sprayed trees. Another trial was one fluid ounce of domestic cloudy ammonia to the gallon, with the soft soap. This, although weaker than the ordinary clear ammonia, scorched the edges of open blossoms, and therefore the quantity of ammonia is probably too much. Half the quantity of clear ammonia might serve. The mixture, so far as can be judged from a limited trial, seems more effective in killing suckers than the other washes tried this year. But, although several

other washes have been used in past seasons, the proportion of dead suckers found two days or more after spraying has always been very small. If any reader has had better results, I should be glad to know what wash was used. But the dead suckers must be found in the trusses to prove the success. They are in the trusses in my test cases, so that apparently they do not drop out when killed. *A Southern Grower.*

MEALY BUG ON VINES.—An infestation of mealy bug at this season is particularly to be deprecated because of the difficulty of destroying it by means which at the same time will not harm the vines and the crop. Pure water warm enough to kill does not hurt the foliage or the fruit, but it has the disadvantage of failing to reach every crack and hiding-place, and so is

exposure of the foliage to the vapour. But still there would be a risk. For some time I have experimented with nicotine (98 per cent. commercial) and find many plants not in the least injured by the use of double the strength recommended by vendors, and its fumes destroy all bug, etc. For vines, half the strength recommended has been used, and the little bug found in one viney difficult to keep free on account of Guavas growing in the same structure was all killed. More than one experiment has been made with equally satisfactory results, and the foliage of Lady Downes was not in the least affected. I would like to ask others to try nicotine with equal caution. It has other advantages over cyanide. I find bug usually appears on the part of the young wood of the previous year, and as soon as convenient after growth is well forward the snags

THE CHELSEA SHOW.

FIG. 153.—CALCEOLARIA STEWARTII: FLOWERS YELLOW. (See Floral Committee's Awards, p. 363.)

not perfectly efficient. Watching the appearance of solitary individuals and touching each with a drop of methylated spirits is subject to a like disability and we must fall back on nicotine vaporising or fumes of cyanide. The danger of vaporising the varieties Muscat of Alexandria and Lady Downes with nicotine is well known, whilst the cyaniding is equally apt to damage the foliage. It is not to be disputed that cyaniding is harmless to vegetation under certain conditions. The question is, what are these conditions? For one thing, vine leaves still immature are in a peculiarly susceptible condition, and to cyanide a viney while that condition lasts is always risky. There are, however, precautions which may be taken. If what may be called a full 3 oz. application be used, then 15 to 20 minutes will destroy every living bug, and the chance of harming foliage is reduced to the minimum. There is the other extreme, to reduce the strength to 1 oz. per 1,000 feet and allow a long

should be cut off close to each lateral. In doing this I have repeatedly found bug lurking ready to issue forth when none were to be seen on other parts of the vines. One should always be suspicious of ants in a viney. Once they become active it is a suspicious coincidence that bugs soon appear also. Ants are easily destroyed in the following manner:—Partly fill a pail with boiling water and fill it up with paraffin oil, stir it through the hot water, and after it has all floated to the top spray the paraffin over the border, woodwork, glass, or wherever the ants are found. A few applications will destroy them all. The common-sense practice of having only the primary leaves on laterals—no sub-laterals whatever—is a means of keeping bug in check, and also low night temperatures with early ventilation, or all-night ventilation when weather permits, and the minimum of "damping down" or none at all, are other contributory means to freedom from bug. *R. P. Brotherston.*

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. COOKSON,
Oakwood, Wylam-on-Tyne.

SEEDLING ODONTOGLOSSUMS.—The seeds of *Odontoglossums* and allied genera which were sown in the late autumn and early months of the year are now forming their leaves, and may be transplanted into store pots, either several together or singly in small pots. The later sowings, owing to the dry, cold, unfavourable conditions outside, have not made so much progress as usual. The old seed-beds should be examined, and any seedlings left on the pots from last year should be transplanted if ready. Where only a few seedlings are grown the sooner they are potted off separately the better progress they are likely to make. The advantage of treating plants individually is that attention may be paid to the particular requirements of each. The greatest enemy to seedlings is the destructive maggot, which does considerable damage to the germinating seeds and to plants in the earliest stages of growth. Many successful hybridists have often succeeded in inducing satisfactory germination, only to find, soon after the leaves have been produced, that the plants are attacked by the miniature black fly maggot. Here, also, the advantage of potting plants singly will be observed. There appears to be no satisfactory remedy for the pest. Vaporising at frequent intervals destroys the male insect in flight, but the female hides in the potting compost, where it is difficult for the fumes to penetrate. Spraying with weak insecticide helps to check them, and wiping the pots containing the seeds with a cloth dipped in a very weak solution of carbolic assists in keeping the pests at a distance. Where the potting compost is badly infested, it is best to re-pot the seedlings at the earliest possible moment and burn the old soil. Plants which were put into single pots last autumn will now need attention and those which have made good progress will be benefited by more root-room. It is not desirable when potting seedling plants of *Odontoglossums* and allied genera to disturb the roots unnecessarily. If the potting compost is in good condition, carefully turn the plants out of their pots and transfer them to suitable sizes without disturbing the roots. Much progress is often made by seedlings after the third leaf has been developed, and if encouraged by suitable treatment after this period, it will be found that a satisfactory first pseudo-bulb will be produced, and the plants will flower early. It is advisable to see that the compost used is of a lasting nature. Sphagnum-moss should be sparingly used and chopped very fine. The compost should be graded according to the size of the plants, and attention should be given to the supplying of proper drainage.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

THE IRIS GARDEN.—Irises are extremely useful plants for supplying the floral display in the garden during the transition stage from spring to summer bedding, and although the flower spikes of the German and allied Irises are prostrated by sharp frosts, they soon recover and become erect again, little the worse for the ordeal. The foliage of the flag Iris, even when not in flower, is ornamental, both in clumps or beds in grass. The rhizomes of this section of Iris grow and spread along the surface of the ground, throwing out fresh roots. If the old, exhausted back portions are cut away occasionally, the plants will not need removal often, but will continue to flower well in the same spot for many years. Do not plant in rich, freshly-manured soil, nor practise deep planting. Should any clumps or beds have become so thick and crowded with growth that the plants have failed to flower, lift them as soon as the flowering season is over, divide to single or double crowns and re-plant on a fresh

site in ordinary garden soil. Arrange the portions 1 foot apart, taking the precaution to stick a few Yew or other evergreen branches in the soil amongst them for shade until the plants are re-established. Secure, at the same time, surplus plants for the reserve garden to make good any losses that may occur. The varieties of the pallida section possess handsome foliage and beautiful flowers, and thrive in any situation, whether sunny or shady. Few plants are more strikingly handsome than *J. Kaempferi* with its gorgeous shades of soft, rich colours. The plants grow best in damp situations, such as on the margin of a stream or pond, but require a more generous treatment than their congeners of the German section. Ground intended for planting with Japanese Irises should be dug deeply, and manure should be placed in the bottom of the trench sufficiently deep to be below the roots. We plant *J. Kaempferi* in the spring, and have been very successful with imported clumps, as sent over in 6-inch squares of natural soil. Partial shade seems to suit them, although if the rooting medium is congenial they grow well in full sunshine. *Iris stylosa* may be propagated now from portions pulled from established plants. Plant this beautiful winter-flowering species in the warmest corner.

FLOWERING SHRUBS.—The best time to prune flowering shrubs is after the flowers are over. Old flowering branches that show signs of exhaustion should be cut clean out, also weak, twiggy growths that tend to crowd the interior of the plant. Endeavour to obtain fresh, strong shoots from where the old branches were cut back. When planted in beds of a kind, one or more of the plants may be cut to within 1 foot of the ground each year. This will result in a good crop of healthy, flowering shoots for the next season. *Berberis Darwinii*, *B. stenophylla*, and other evergreen flowering shrubs, may be pruned less severely.

ROSES.—As a precaution against infestations of *Aphis* syringe the bushes twice a week with *Quassia* extract, or *Quaezol*, employing one pint to 10 gallons of soft water.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY,
Knowsley Hall, Lancashire.

GREENHOUSE RHODODENDRONS. Varieties of *Rhododendron* such as *Purity* (white), *Countess of Haddington* (blush white), *Lady Alice Fitzwilliam* (white), and *Edgworthii* (white tinged with pink) make beautiful subjects for the decoration of a conservatory or corridor. They may be grown in large pots and the shoots trained to wires suspended from the roof or over wire shapes fashioned as balloons. Now is a suitable time to ascertain the condition of the soil and drainage. It is not advisable to repot the plants annually; it will suffice, if the soil is in a good condition, to give a top-dressing of peat and silver sand, making the materials very firm by ramming. If repotting is necessary, use slightly larger pots and make the compost very firm around the ball of roots. Repotted plants should be grown in a little heat until the roots are re-established. Train in the shoots and pinch out the points of extra strong growths, to secure shapely specimens. Syringe the underside of the leaves to destroy thrips. Plants of *Rhododendron indicum* (*Azaleas*) may be treated similarly to the above. Remove the seed-pods and promote a clean healthy growth by syringing the foliage daily. Feed the roots with weak manure water.

GARDENIA.—Plants that have flowered should be placed in an intermediate house where they can be syringed freely. Prune the plants into shapely specimens and when the subsequent growth is 2 inches long they may be repotted, using a compost consisting of equal parts fibrous loam and peat lightened with sand, and enriched with a little bone-meal. Keep the plants growing actively, syringing them on frequent occasions and sponging the leaves to free them from mealy bug and brown scale. Pot rooted cuttings and pinch out the points of the leading shoots to ensure shapely plants, but discontinue stopping the growths about July, when the plants should be placed in plenty of light and air to ripen the

wood. As young plants produce the finest flowers, it is advisable to propagate new stock each season to replace those that are two years old.

HOLBOELLIA LATIFOLIA.—This beautiful greenhouse climber is worthy of a place in every establishment. If planted in a border the roots should be grown in a limited space. Train the growths to pillars or to wires suspended from the roof-rafters. The delicate perfume of the flowers scents the whole of the greenhouse. Cuttings may be inserted in sandy soil now and rooted in a temperature of 60°. Syringe the plants when out of flower and remove all weak growths.

LACHAENALIAS having finished flowering, water at the roots should be withheld gradually. Place the pots or baskets in a frame exposed to full sunshine to ripen the bulbs.

POT ROSES are now sufficiently hardened and may be plunged out-of-doors to the rims in ashes. Select a sheltered situation, but exposed to full sunshine. Water the roots with extra care and feed them occasionally with liquid manure.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton
Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buck-
inghamshire.

THE ORCHARD HOUSE.—Attend carefully to such important details as ventilating the house, watering the roots, and keeping the atmosphere moderately moist. Apricots that are at the stoning stage should be thinned for the last time. Do not overcrop the trees, and especially those in pots; a fair-sized tree growing in a 10 or 12 inch pot may be allowed to carry about two dozen fruits. Pinch the shoots closely, to cause fruit-buds to form. Stopping Apricots by the finger and thumb is far preferable to knife-pruning, which frequently causes gumming. Guard carefully against the caterpillar, which feeds upon the tender foliage. Syringe the trees in bright, sunny weather, but less frequently on dull days. Pinch the shoots of Peaches growing in pots when about 4 or 5 inches long; the lower buds will be benefited by this. Keep the shoots thin, for an excess of growth is a frequent fault in the culture of pot-trees. Continue gradually to thin the fruit, and watch carefully for green and black fly. Remove all decaying leaves, and afterwards dust the trees with tobacco powder, which, if applied just after the trees have been syringed lightly, will destroy the fly in a few hours. Syringe the trees with clear water afterwards to cleanse them: it is possible to keep Peach trees almost if not quite free from green fly by syringings of clear water alone. Pinch closely the young shoots of Plums and Cherries, and water their roots freely, never allowing the foliage, whether of trees in pots or borders, to flag for want of water. A little liquid manure may be afforded the roots at every alternate watering. Top-dress pot-bound trees with a mixture of well-decayed manure and fresh fibrous loam in equal proportions, adding a sprinkling of wood ashes or bone-meal. Syringe the foliage freely during the early morning and again in the afternoon, closing the house when the temperature is from 65° to 80°, according to weather.

PEACHES AND NECTARINES.—Trees with fruits on the point of maturity should be fed liberally. Admit air freely during bright, sunny weather, and syringe the foliage twice daily. Soft water should be used, as hard water may spoil the appearance of the ripe fruit. Attend to the thinning and tying of the young shoots of trees in late houses, admit air freely, and use every means to keep the foliage healthy and clean. Feed the roots as occasion requires.

PINES.—The night temperature for Pines in fruit should be 75°, and in the daytime from 80° to 90°, or even higher on bright days, when an abundance of air is admitted. Close the ventilators with the temperature at 80° or 85° and well syringe all bare surfaces, but not the plants themselves. Some of the suckers from last season's fruiting plants, which were potted during the autumn, are beginning to show fruit. Maintain a humid atmosphere and lightly dew

the plants overhead with a fine syringe on warm, bright days at the time of closing the house.

FIGS.—Maintain a dry and rather warm atmosphere in houses where Figs are ripening, but admit plenty of air. In later houses maintain an atmosphere as close, warm and humid as is consistent with the health of the trees. Well syringe the trees overhead twice daily and damp all available surfaces during hot, drying days.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOTE, Eastwell Park, Kent.

DESERT CHERRIES.—Cherry trees are among the first to be attacked by black fly, which appears shortly after the fruit is set. Every effort should be made to exterminate this pest at once, or it will increase with great rapidity, injuring the delicate points of the young shoots and spoiling the fruit. Syringe the trees with a reliable insecticide, and afterwards wash them thoroughly with clear water. If the flies are not all removed by one operation it should be repeated on successive afternoons. Remove gross shoots, which might disturb the balance of the tree, and pinch at the fourth or fifth leaf all those not required for extension. Keep the growths thin, so that each shoot receives the maximum amount of sun and air.

PROTECTIVE MATERIALS.—Canvas blinds, nets, or other coverings which have been employed to protect fruit trees from frost may now be removed. If, however, inclement weather occurs, the coverings may be replaced for a few more nights. So far, late spring frosts have done very little damage in this locality. On several occasions when the thermometer has fallen it happened that the trees were rather dry, and thus escaped injury. Blinds should be dried and labelled before being stored. Care should be taken to guard against damp and the attacks of mice.

BLACK CURRANTS are now growing rapidly, and the trees, except those attacked by the mite, are looking extremely healthy. Strong, vigorous bushes are always able to withstand both insect and fungous pests much better than old, half-starved ones, and as the young shoots of the previous year fruit best, the bushes should be encouraged to make growth by an occasional dusting of the soil with artificial manure during showery weather. Where big bud has been found, persevere with the treatment recommended in previous calendars, following this up by picking off and burning affected buds. Young bushes planted last autumn should not be allowed to carry much fruit. The better plan is to cut them back hard, thus encouraging the production of strong basal shoots, which will fruit well next season. Black Currants are subject to attacks of green fly in some seasons. They should be frequently examined for this, and if any signs of the pest are seen, measures should be taken to clear the bushes at once. If left many days the fly will cause the leaves to curl in such a manner that it will be impossible to dislodge the insects by ordinary means, and much damage will result.

RED CURRANTS.—The same measures should be applied to Red Currant bushes, as to Black. Apart from injury to the shoots, if the bushes are not kept free from insects, the fruit is made dirty and unfit for use. Keep the fruit quarters hoed, both to eradicate weeds and to maintain the surface soil in a loose and friable condition. This, combined with mulching as required, will keep the trees in good health during a dry period. It is far more effective than watering, though this latter operation may also be necessary in the case of recently transplanted trees.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

VEGETABLE MARROWS.—The plants should not remain for long in pots, or they will become starved and fail to grow freely when planted. It is not essential to plant Marrows in manure exclusively, for the plants do very well in ordinary fertile soil. For a time they should be protected at night and during periods

of high winds. Four main shoots are sufficient on each plant, and all fruits should be cut young, at least during the summer months.

ONIONS.—This crop is succeeding well, and needs only occasional attention in such matters as hoeing and applying manurial dressing. The hoe should be run through among the plants at 10 to 14-day intervals, and soot, pigeon manure, and concentrated fertilisers applied about once a fortnight. It is remarkable the amount of "feed" the Onion is capable of appropriating to its palpable benefit. Provided the ground was properly prepared and these cultural methods adopted, watering is not essential. I have no water to spare, and even in such dry seasons as those of 1911 and 1913 our Onion crops were satisfactory.

SEAKALE.—It sometimes happens that some of the crowns left for latest supplies are never cut, and if they are lifted carefully, re-planted and watered, they become re-established without much of a check, and afford splendid material for early forcing. If they show signs of flowering the stems should be cut off, but these are never so good for forcing as those which make foliage only. The plants set from thongs are beginning to grow freely, and a dressing of pigeon manure or artificials will give them an extra fillip. At the same time these dressings are not so important as they are for Brassicæ.

LEEKS.—Should the seedlings hang growth as they are apt to do, apply a stimulating dressing such as pigeon manure and soot, or, failing these, superphosphate of lime and nitrate of soda in equal proportions, and after applying them stir the ground thoroughly between the rows. Should the weather be dry a moderate application of water will be helpful. Leeks planted a few weeks ago will progress all the better for an occasional supply of weak manure water at the roots. It is usual to prepare ground for the main crop earlier in the year, but where this has been overlooked the work should be done as soon as possible, the important point being to introduce a 10-cwt. to the rod dressing of rotted cow manure at least 1 foot under the surface. Leeks are particularly valuable in late spring and at this time of the year. Any plants of last year's crop still in the ground should now be lifted and laid in a cool place for future use.

HERBS.—Plant out Basil and other tender herbs on a warm border, allowing each plant a foot of space. Hardy kinds such as Thyme, which are being increased from seeds sown early in the year, should be thinned meanwhile to 6 inches, before they crowd each other. Shear off the tops of Sorrel running to seed, and make an occasional sowing of Chervil where it fails to keep up a supply from self-sown seeds.

THE "FRENCH" GARDEN.

By PAUL AQUATIAS.

NURSERY BEDS.—Beans sown in frames should be ready for transplanting out-of-doors soon. Another sowing may be inserted either in 60 pots or direct in the soil of the frame for a succession. Plants of the batch of Celery raised in February must on no account receive a check at this period from either dryness at the roots or inefficient ventilation, for this would cause bolting in July or August. The main batch sown in March should now be pricked out in frames preferably, though when no space is available a temporary bed may be made by spreading 3 or 4 inches of manure in a sheltered corner, and covering it with a few inches of soil. The last batch of Cauliflowers should be planted in a well-prepared bed in the open, where root-waterings can be afforded frequently. Sow the seeds very thinly to obtain a sturdy growth. This batch will be available for planting as an intercrop among the Melons, or to follow the present crop of Cauliflower now growing on the manure beds; they are also useful as a stop-gap to fill ground when the supply of Celery plants is short. Tomato plants should be hardened gradually for setting out in a fortnight's time. The shelter of the lights must not be disregarded at night-time in case of late frost, and the frames should be sufficiently raised to keep all the leaves

clear of the glass. If cloches are at liberty set the best plants on a south border and cover the glasses for a period of three or four weeks. Ridge Cucumber seeds may be inserted at 2 or 3 inches apart in a cold frame, which should be covered with lights and mats till the cotyledons appear. Sow two seeds in each 60-sized pot and plunge the latter in the frame.

MELONS.—The planting of this crop is the most important operation during May. A trench having been prepared in advance, it should be filled with good manure, which should be watered and trodden firmly. Set the frames lengthways, allowing a good slope towards the front. After having marked the site of the next trench, throw the soil therefrom into the frames just placed in position; level it and make two holes in the centre, where the Melon plants will be set. Fill the holes with black soil, place the lights in position, and cover them with mats for a few days. When the bed is warmed sufficiently by fermentation of the materials, plant the Melons six for every frame. Keep the lights closed and covered for three or four days, after which the shading may be removed gradually until, when the plants are well established, it may be dispensed with altogether and ventilation afforded. To be successful with this crop it is essential to keep the plants as hardy as possible without subjecting them to a check from low temperatures. The bulk of the Melon plants should be set this month, reserving a few beds to be set in June, when the frames and lights will be available for the Vegetable Marrows.

OUTSIDE CROPS.—Owing to the pressure of work in other departments the crops out-of-doors are apt to be neglected, unless the careful cultivator plans the work accordingly. The work of hoeing and watering the Lettuces and Cabbages must be done to hasten their growth. Radishes and green Onions need bunching. Spinach must be gathered, and ground intended for the Kidney Beans well broken and hoed deeply. Endive sown in March should be transplanted at a distance of 12 inches each way in the open. Do not set the plants deeply, and keep the foliage moist by light waterings. Endive thrives best in rich ground and is chiefly cultivated at this time of the year as an intercrop. The plants should be sufficiently established before setting the main crop. Accommodation is now made for the first sowing of Witloof Chicory. This useful crop does well in deep, rich ground, and the seed is sown in drills very thinly, the latter at 1 foot apart. This crop can also be sown in nursery beds where no room is available at present. The roots pricked out produce better and thicker crowns when forced than the others, though this method entails extra labour.

THE APIARY.

By CHLORIS.

SHORTAGE OF BEES.—The daily Press informs us that a large number of Dutch bees are being imported into the Eastern Counties, and that they are immune from the Isle of Wight disease. This is very good news, and that it may prove true will be the fervent wish of all who have the interests of apiculture at heart. At the same time we must not take too sanguine a view of the matter, because the experiment will require the test of at least three or four years before any certain verdict can be pronounced upon it. This must not be taken to mean that I do not regard the experiment favourably. The English bees may have degenerated more than we are aware of by the constant in-breeding that undoubtedly takes place. I know a large village where, to my knowledge, no bees have been introduced, either as swarms or queens, for more than twenty-five years, nor can anyone remember any being introduced. No one who knows anything about rearing stock will affirm that this practice is good for the virility of the race.

PAINTING.—Where painting has been neglected all arrears should be made up with as little delay as possible, recollecting that uniformity in colour should be avoided, as young queens often return to the wrong hive after their wedding trip through inability to distinguish the hive from which they emerged.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.
Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MAY 25—

Linnean Soc. Anniversary meet. at 3 p.m.
 Rhododendron Sh. at R.H.S. Hall (5 days).

THURSDAY, MAY 28—

Bath and West and Southern Counties Soc. Sh. at Swansea (5 days). Royal Botanic Soc. meet.

FRIDAY, MAY 29—

Royal Botanic Soc. lecture by Professor W. B. Bottomley.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 55.98°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, May 20 (6 p.m.). Max. 76°. Min. 51°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, May 21 (10 a.m.): Bar. 30.2; Temp. 70°. Weather—Bright Sunshine.

PROVINCES, Wednesday, May 20: Max. 73°. Cambridge; Min. 50°. Stornoway.

SALES FOR THE ENSUING WEEK.

TUESDAY—

First Annual Sale of Bedding and other Plants, at the "Home of Flowers," Swanley, by Protheroe and Morris, at 12.

TUESDAY, WEDNESDAY, AND THURSDAY—

The entire collection of Orchids formed by the late J. J. Holden, Esq., of Lancashire, at 67 and 68, Cheap-side, E.C., by Protheroe and Morris, at 1.

WEDNESDAY—

Hardy Bulbs and Roots, at 1. Dwarf Japanese Trees, at 3.30. Palms and Plants, at 5. At 67 and 68, Cheap-side, E.C., by Protheroe and Morris.

The Chelsea Show.

The Royal Horticultural Society is to be congratulated on one of the most brilliant shows ever held in this country. Favoured by weather so fine as to satisfy all but the most delicate subjects—whether human or plant—the Chelsea exhibition attracted a vast concourse of people, and although it did not bring to light any specially remarkable novelty it proved that the standard of cultivation is as high as it can well be. Moreover, and speaking generally, the display of the exhibits was remarkably good, and exhibitors for the most part demonstrated the fact that air and space between their groups lend a natural aspect and an added attractiveness to the groups themselves. The relegation to the ground level of all the groups in the great tent—except the end groups of Orchids—must be pronounced a complete success. It gives an independence to each and a spaciousness to all which allows the visitor to imagine himself in a garden and not in a flower shop.

The laborious work of organisation was carried out with an ability and devotion which reflect the greatest credit on the officers of the Society. The membership of the Society has increased so greatly of recent years that Fellows—even in the roomy spaces of Chelsea—had some diffi-

culty in gaining an entrance when the show opened at 12 o'clock, and it may be that the Society will be obliged, on future occasions, to give the holders of a Fellow's ticket priority of entrance over those who carry "transferable" tickets.

The Exhibition was honoured by a visit from Queen Alexandra, who showed her appreciation of its merits by making a prolonged stay.

The exhibits of the leading firms were of the high standard of excellence which we have been led to expect of them.

Of the rock gardens, which have achieved such wonderful success and admiration during the past few years, there is little to be said. They showed a high level of general excellence, but there was not one among them—good as many were—that stood out pre-eminently like Mr. Wood's rock garden of last year. It is as though the rock-garden architects were enjoying a pause in inventiveness, and in the meantime are content to reproduce the features which have won them such well-deserved distinction in the past.

A regret was general among the real gardeners present at the Exhibition that more prominence and particularity is not given to novelties, and there is a general feeling that the Society might follow the example of the National Rose Society and contrive that all novelties shall be exhibited together in some prominent situation. Of the novelties exhibited in the tent allotted thereto mention should be made of the Irises of Mr. Dykes.

Perhaps the most noteworthy feature of this noteworthy show is the thoroughness with which the "sundries"—those all-important adjuncts of the garden—are now represented, and the R.H.S. may claim to do for all branches of Horticulture what the sister society has done for Agriculture on the occasion of the annual exhibition.

It will be a matter of general regret if the magnificence of the trade exhibits should tend to slacken the zeal for exhibiting on the part of the amateurs. Most distinguished among the amateur absentees was Sir George Holford; but we understand that this lapse is but temporary, and we shall hope to see again in the near future the superb specimens which have won him world-wide fame.

The attendance on the opening day was phenomenal—greater, so it is said, than at the International Exhibition—and nothing was more striking than the business-like and instructed way in which the majority of visitors carried out their inspection of the plants. For providing instruction in so pleasant a manner the Society and the exhibitors deserve the warmest thanks of all good horticulturists.

Coloured Supplement.—The subject of the Coloured Plate published with this issue is a new variety of the Collette Dahlia, an attractive section comprising many good garden plants. "Tuskar" has richly-coloured florets tipped with white, while the collette itself, a pale cream colour, gives the needed touch of variety and softness to the effect. The plant has a free habit, and grows to a height of three feet.

EXHIBITIONS OF RHODODENDRONS.—Messrs. JOHN WATERER, SONS AND CRISP announce that they are holding their Annual Exhibition of Rhododendrons and other plants in the Royal Horticultural Hall from Monday, May 25, to Friday, May 29. The exhibition will open on Monday at 2 p.m. Messrs. WATERER, SONS AND CRISP are also holding an exhibition of Rhododendrons and Alpine plants at the Royal Botanic Gardens, Regent's Park, N.W., for two or three weeks from June 8. The exhibition will be opened on that day by Her Highness the Duchess of Teck at 3 p.m.

PRESENTATION TO A GARDENER.—Mr. JOHN POTTER, gardener to Sir WILLIAM MAXWELL, Bart., Cardoness, Kirkcudbrightshire, is leaving Cardoness. To mark the occasion his friends have made him presentations of two purses of sovereigns.

BATH AND WEST AND SOUTHERN COUNTIES SOCIETY.—The annual show of this agricultural society will be held at Swansea on May 28, 29, 30, and June 1 and 2. Besides exhibits of a purely agricultural character, there will be a section devoted to horticulture, and the gardening exhibits will be accommodated in a special pavilion.

DAMPING OFF.—The malady of damping off is, as is well known, due to the attack of the fungus *Pythium de Baryanum*, following on unfavourable conditions—excess of moisture and defect of light. That these are generally the causes is certain, for those who make a study of damping off know that in some years it is by no means easy to find the fungus even in boxes of seedlings which have been purposely subjected to adverse conditions, whence it is to be inferred that ill-treatment without the fungus is not enough to bring about the symptoms of the disease. Again, the symptoms familiar to most gardeners—a softening at the collar of the plant and a bending or falling over of the seedling—are sometimes observed even though the *Pythium* is absent. The reason appears to be that damping off may be caused not only by *Pythium*, but also by another fungus—a species of *Rhizoctonia*. Mr. J. JOHNSON, who is responsible for this observation (*Bulletin* No. 31, University of Wisconsin Agricultural Experimental Station), has observed the *Rhizoctonia* as well as the *Pythium* on seedlings of many different plants—Cress, Tobacco, Lettuce, Tomato, etc. By treatment with formalin 1 : 50 the soil to be used may be sterilised and the disease prevented. A cheaper means of effecting this purpose is steam sterilisation, which method has the further advantages of destroying weed seeds and insect pests, and in inducing a more vigorous growth of the seedlings.

"EXPLOSIVE FORCE" OF DECAYED IVY.—A report appears in the Press that the ARCHDEACON OF NOTTINGHAM, in his visitation address at Southwell, stated that when the "roots and tentacles" of the Ivy undergo decay they exercise a powerful explosive force. Inasmuch as the main point insisted upon—that Ivy is apt to damage masonry—is undoubtedly correct, it may seem unnecessary to point out that the foregoing statement appears to contain two fallacies. First, Ivy does not possess tentacles, and second, that the decaying roots do not exercise explosive force. The damage done by Ivy is to be ascribed not to the decaying, but to the living roots and stems. Like other plant tissues, those of the Ivy roots are capable of setting up enormous pressures—pressures of the order of 300 to 600 lbs. to the square inch—and it is pressures such as these exercised by the roots which penetrate into the masonry which set up cracks and do damage. This damage is, of course, rendered all the more certain by the condensation and accumulation of moisture due to the luxuriant mass of foliage. That the aerial roots of the Ivy serve not only as holdfasts but also as absorbing

COLLERETTE DAHLIA "TUSKAR"
(RAISED BY MESSRS. DOBBIE & CO.)

organs appears probable from the fact that even after the main stem is severed Ivy firmly attached to a wall may continue to live for some years. During this period it must obtain all the water and mineral substances which it uses from the water condensed on the walls. Hence there would appear to be some justification for Shakespeare's analogy:—

"The Ivy which hid my princely trunk,
And suck'd my verdure out on't."

The idea that plants possess tentacles seems very widespread among well educated people. We remember, for example, hearing a K.C. descant in court upon the dry-rot fungus, and describe in harrowing terms how the fungus spread wide its deadly tentacles, crushing the walls of houses in its cruel embrace.

THE HORTICULTURAL TRADES' ASSOCIATION.—At a dinner of the Horticultural Trades Association of Great Britain and Ireland, which took place on Tuesday last at the Hotel Windsor, Mr. W. CUTHBERTSON presided and Sir HARRY VEITCH was the principal guest. In the course of the evening Sir HARRY spoke of the nursery and seed trade during the past fifty years.

CEMETERY SUPERINTENDENTS' ASSOCIATION.—The First Annual Congress of the United Kingdom Association of Cemetery Superintendents will be held in London on July 15 and 16. On the first day five of the largest Metropolitan cemeteries will be visited, and in the evening a dinner and the annual meeting will be held at Anderton's Hotel, Fleet Street. On the second day, at the invitation of the President, the members will visit the City of London Cemetery and Crematorium at Ilford.

YORKSHIRE GALA.—The Grand Yorkshire Flower Show and Gala will be held on Wednesday, Thursday, and Friday, June 17, 18, and 19, in the Bootham Park, York. We are informed that the exhibition promises to be unusually successful. The collection of cactaceous plants which was formed at Cannes by the late Mrs. VYNER, and recently brought from there to England, will be exhibited by Mr. R. C. VYNER. Amongst them there are some very rare and unique specimens that were bought from the Abbé BENGUIN shortly before his death.

PRESENTATION OF A PORTRAIT OF LINNÆUS.—A framed portrait of LINNÆUS has been presented to the Herbarium of the Royal Botanic Gardens, Kew, by Sir ARTHUR CHURCH, K.C.V.O. It is a very good impression of an old French colour-print by P. M. ALIX after A. ROSLIN. The portrait is half-length, and represents LINNÆUS clad in wig and dark fawn-coloured coat and vest. Through the opening of the latter protrudes a delicate white frill, while on the left-hand side of the coat hangs the Order of the Polar Star, with a sprig of *Linnaea borealis* above it.

THE DISCOVERY OF OLD METHODS.—The complacency of the world is disturbed from time to time, but not for long, by the discovery that this or that contrivance or method which it thought was its most recent invention was known to the ancients. Only the other day elaborate steel surgical implements were found which show that the Greeks were deft and advanced surgeons. Dry farming has of recent years been rediscovered in several parts of the world. A system of manuring fruit trees by adding the manure to holes at some distance from the bole of the trees is now enjoying considerable prominence in the horticultural Press. How old is this method may be judged from the concluding passage in LINDLEY'S *Theory and Practice of Horticulture*, 2nd edition, 1855: "The Dutch, who are admirable gardeners, had in the Great Exhibition an instrument called 'earth borer,' for manuring fruit trees without digging the ground. A circle of holes is bored round the tree at 2 feet distance from the tree and a foot from each other. . . . They are 18 inches deep (where there is enough depth of soil) and slanting towards the centre; are filled with liquid manure, diluted more or less in dry

weather, and stronger as the weather is wetter." Truly, *tout passe, tout lasse, tout casse: et tout repasse.*

NURSERY STOCK IMPORTS, U.S.A.—The *National Nurseryman* publishes a list of the annual importations of nursery stock by the United States. They total 44 millions all told. Of fruit trees the total is about 4 millions, of which number France supplies about 3½ millions; of other countries Germany sends a mere 73,000, and England and Scotland some 6,000. Fruit tree stocks number 17 millions, of which France supplies no fewer than 16½ millions, Holland comes next with half a million, England a bad third with ¼ million, and Ireland with 65,000 beats Scotland, which can only spare 41,000. Of the 167,000 Grape vines which emigrate, 164,000 are of French descent. England and Scotland, however, beat the rest of the world in the matter of bush fruits, England's yearly parcel being 81,000 and Scotland's 75,000 out of a total of 200,000. With a courtesy which does credit to us and to her America buys the major part of her Roses from England—1,632,252 out of a total of some 2 millions. In the supply of Rose stocks England is also first with upwards of 2 millions, as against less than a million sent by France and about half a million by Scotland. Ireland sends of Roses 107,000, and of Rose stocks 470,000. In the year under review that island also sent two Grape vines and one forest tree. France occupies a position of amazing pre-eminence, with a grand total of 30 million plants exported each year, as compared with 2½ millions from England; Scotland ¾ million and Ireland not far short of that number.

BOTANICAL PROGRESS IN BRITISH COLUMBIA.—It is interesting to learn that botanical work in British Columbia is making rapid progress. A complete botanical survey is to be made, and a herbarium is being formed. In the past three years several thousand specimens have been obtained, some being new species. Specimens and information are supplied from the various neighbourhoods by local residents; or, if there are no such correspondents, exploration trips are made. The Surveyor-General, whose men are exploring new regions of British Columbia, allows them to collect material and data for the botanical survey. Last year the formation of a botanic garden and arboretum was begun, and over 1,500 native seed plants are to be cultivated. Already 500 species are established, and it is hoped that the collection will increase the interest of the public in the wealth and beauty of their native plants. It is expected that another botanic garden will be started this summer in connection with Stanley Park on the Pacific coast.

THIELAVIA ROOT-ROT OF VIOLETS.—In the course of an account of the diseases which affect Violets, Mr. D. REDDICK, Professor of Plant Pathology, Cornell University, describes in detail (*The American Florist*, March 28, 1914) the symptoms set up by *Thielavia basicola*, the fungus which causes root-rot. The disease, which was recognised in Europe 60 years ago, causes an arrest of growth of the leaves, which become dwarfed, wrinkled and yellow. The underground stems of affected plants are cracked and rough, brown or black lesions occur on the roots, sometimes girdling them completely. They may be recognised readily by their contrast with the whiteness of unaffected roots. Similar lesions may appear on the leaf petioles and runners. In its earliest stage the lesion appears as a small water-soaked spot, but as it increases the centre becomes whitish and the margin black. For the prevention of the spread of the disease Professor REDDICK recommends care in the selection of cuttings, advising that no plants which show the characteristic lesions should be used for propagation. He further recommends that the cuttings be struck in fresh sand, or if old sand—used previously for the purpose—be employed, sterilisation of the sand by means of formalin (1 pint to 12½ gallons of water). The solution

should be sprinkled over the cutting-beds at the rate of 1 gallon per square foot, and the bed covered with oilcloth for 12 hours. The covering should then be removed and the sand or soil stirred in order to facilitate the evaporation of the formalin. Soil in the houses should also be disinfected—if possible, by steam. As shown by Mr. CHITTENDEN, the disease is encouraged by careless and excessive watering.

THE FRENCH LAVENDER INDUSTRY.—According to the *Journal of the Royal Society of Arts*, May, 1914, the continuous rise in the price of Lavender essence has resulted in a considerable increase in the acreage devoted to the cultivation of this plant in the Marseilles district. The fact that barren soils, unproductive for other purposes, may be successfully utilised renders the industry particularly attractive to the farmers of Southern France. Thin rocky soils well exposed to the sun, situated at an altitude of 1,300 to 4,000 feet, are best adapted for the purpose. Experience shows that Lavender cultivated at altitudes of 3,000 feet produces the best essence. The flowers are gathered during August. In the Department of the Vaucluse, where about 10,000 acres are under cultivation, the gatherers receive about five shillings and eightpence per 100 kilogrammes (220 lb.), which represents somewhat less than one day's work. Immediately after the flowers have been gathered they are placed in a cylinder pierced with holes, which in turn is placed in a boiler, the diameter of which is only slightly greater than that of the cylinder. In the boiler is a tripod upon which the cylinder rests. Water is introduced to a level with the top of the tripod, and the steam therefrom passes into the cylinder containing the flowers and thence into a serpentine pipe, where it is condensed.

LIGULARIA SPECIOSA AND L. STENOCEPHALA.—Mr. A. PURPUS, Inspector of the Botanic Garden in Darmstadt, describes, in *Möllers Deutsche Garten-Zeitung* (No. 14, 1914), two most promising plants which he has had the good fortune to raise from seed sent from Eastern Asia. They are *Ligularia speciosa* (Fisch. and Mey.), and *L. stenocarpa*. From the description it appears that both of these species are superior as garden plants to *Senecio (Ligularia) Wilsonianus*. The former is native of Manchuria, Korea and other Far Eastern regions; the latter occurs in Manchuria and Japan. Both are massive plants, bearing flower-stalks which reach a height of about 2 yards, and hence are only suitable for growing in masses in large gardens. *L. speciosa* is a most imposing plant; its leaves are large, dark-green, heart-shaped and long-stalked. The flower-stalk is green, somewhat hairy, and bears slender pyramids of deep-yellow flowers. *L. stenocarpa* has a similar habit, but its smooth leaves and flower peduncles are red-brown, and the latter taller and more slender than those of the other species, and its flowers are of a yet darker yellow. They do well in moist, well-manured ground, flower from the beginning of July until the middle of August, and are not susceptible to frost. The relation between *Ligularia* and *Senecio* is close, but good authorities hold that the genera should be maintained. This is the more to be desired in that there are already known *Senecio speciosus* (Willd.) from South Africa and *S. stenocephalus* (Boiss.) from the Caucasus.

PUBLICATIONS RECEIVED.—*My Garden in Summer*. By E. A. Bowles, M.A. (T. C. and E. C. Jack.) Price 5s.—*Makers of Modern Agriculture*. By W. Macdonald, D.Sc., London. (Macmillan and Co., Ltd.) Price 2s. 6d. net.—*Bulletin of Popular Information*. (Arnold Arboretum Harvard University, Jamaica Plain, Mass., U.S.A.) May 7, 1914. No. 53.—*Le Bon Jardinier*. (Librairie Agricole de la Maison Rustique, 26, Rue Jacob, Paris.) 150th edition.—*Journal of the Board of Agriculture*. May, 1914. Printed by J. Truscott and Son, Suffolk Lane, E.C. Price 4d.

ROYAL HORTICULTURAL SOCIETY

EXHIBITION AT CHELSEA,

May 19, 20 and 21.

THE show held on the above dates surpassed by common consent any previous exhibition arranged by the Royal Horticultural Society. The season appears to have been particularly favourable to most plants, and exhibitors and those responsible for the management of the show have had the benefit of two years' experience of the Chelsea site, with the result that the arrangement this year was a great improvement on that of

more effective, than those of the old style. The space also provides opportunity for the exhibition of features which are not strictly floral, but which add greatly to the beauty of the show; pergolas covered with climbing Roses, summer-houses with cunning little chairs which invite to repose, fountains with clear running water and wise maxims, and many other "garden delights."

At the Spring Exhibitions, Orchids have

Secretary, the Rev. W. Wilks; the Assistant Secretary, Mr. Gaskell; the Superintendent, Mr. S. T. Wright, and his assistant, Mr. Bisset; and also to the office staff, from Mr. Frank Reader downwards.

Orchids.

AWARDS.

FIRST-CLASS CERTIFICATE.

Miltonia J. Gurney Fowler (*veillaria Memoria G. D. Owen* × parent unknown) from Messrs. ARMSTRONG AND BROWN, Tunbridge Wells. A very large flower of clear rose pink, with ruby-red mask to lip.

Miltonia The Baroness (*veillaria Memoria G. D. Owen* × parent unknown), from Messrs. ARMSTRONG AND BROWN. A fine white flower, with dark crimson mask, changing to ruby-red.

Miltonia veillaria Laelin Sander, from Messrs. SANDER AND SONS. A sterling novelty, the flower being florally perfect and new in colour. The ground colour is primrose yellow, the mask of the lip being purple, and a rose-purple flush showing at the bases of the petals.

Miltonia veillaria Solum from Messrs. SANDER AND SONS. Flowers large bluish-rose, with white margin and very dark mask to the lip.

Miltonia Princess Victoria Alexandra, from Monsieur CHAS. VUULSTEKE, Ghent. A charming white form, with dark plum-coloured mask.

Odontoglossum Queen Alexandrina (parentage unrecorded), from Messrs. CHARLESWORTH AND Co., Haywards Heath. A beautiful hybrid of the *O. illustrissimum* class. Flowers of deep claret colour, with white margins.

Laelio-Cattleya Medina Excelsior, from Messrs. FLORY AND BLACK, Orchid Nursery, Slough. A very handsome *Laelio-Cattleya* with the broad, flat petals of a good *C. labiata*, sepals white, front broad, dark ruby-red, with yellow lines at the base. (*L.-C. Canhamiana alba* × *C. Mrs. Myra Peeters*.)

Laelio-Cattleya Haroldiana Bronze King, from Messrs. STUART LOW, Bush Hill Park, and Jarvisbrook, Sussex. A fine form of the favourite hybrid of good shape. Sepals and petals bronzy-yellow, with a pale rose-shade; lip claret-purple.

Odontioda Bradshawiae Perfection, from Messrs. J. AND A. McBEAN, Cocksbridge. One of the best of *Odontiodas*, and far in advance of others of its class. Flowers large, bright scarlet with a mauve shade, the broad lip being lighter.

AWARD OF MERIT.

Brasso-Cattleya Shilliana (*C. Mossiae* × *B.-C. Digbyano-Mossiae*), from Messrs. ARMSTRONG AND BROWN. A charming flower nearest to *C. Mossiae* in shape, but with an amply-fringed lip. Flowers rose-pink, with yellow disc to the lip and some rose-coloured lines.

Odontoglossum Chantecteur (parentage unrecorded), from Messrs. ARMSTRONG AND BROWN. Flower distinct in colour, orange-red with white margin, and white front to the lip.

Laelio-Cattleya Fascinator-Mossiae var. Purity, from Messrs. CHARLESWORTH AND Co. A true albino. Flowers white, with lemon-yellow disc to the lip.

Odontoglossum Dusky Monarch (parentage unrecorded), from Messrs. CHARLESWORTH AND Co. Flowers of fine shape and deep claret colour with a few white markings and margin.

Laelio-Cattleya Sunstar (*Andromeda* × *Myra*), from Messrs. CHARLESWORTH AND Co. A very fine yellow hybrid, larger than either of the parents.

Odontonia Roger Sander (*Miltonia Warszewiczii* × *Odontoglossum percultum*). A most floriferous hybrid, with upright spikes of mauve-

(See Orchid Awards.)

last year and of the International Exhibition of 1912. The beauty and spaciousness of the Chelsea Hospital grounds, and the comfort and pleasure attending the exhibition, provide a satisfactory contrast to the conditions that were inseparable from the exhibitions held in the gardens of the Inner Temple. One marked result of the change of site has been a wonderfully rapid development in the outdoor exhibits, especially the rock garden. We may recall the old type of rock garden, introduced and faithfully copied year after year; a pool in the middle, stiff, regular banks, rising at the back to an uncomfortable-looking eminence crowned with unnatural Bamboos and showy, misplaced Rhododendrons. Now that the Chelsea site has provided so much scope for artistic effect, the rock gardens resemble "corners of the Alps"; much less pretentious, and, in consequence, far

always taken a prominent place, and the exhibits of these flowers were as grand as ever. They were massed at either end of the large tent, in a position in which they could be seen at a convenient distance.

The other exhibits were all so beautiful that it is difficult to know on which to bestow the highest praise, but the Roses, Rhododendrons, Carnations, Salpiglossis, Calceolarias, Fuchsias, Begonias, Japanese trees and shrubs, groups of stove plants, and masses of lovely foliage plants, were prominent features. The Floral Committee granted 15 awards to novelties, including one First-class Certificate and 14 Awards of Merit.

The weather was warm and bright, and it may be safely predicted that the attendance will constitute a record. For the admirable arrangements the thanks of all present are due to the

purple flowers two inches across. The broad labelum has a bluish-white front.

Cattleya Magali Sander (*Dusseldorfci Undine* × *Mossiae Wageneri*), from Messrs. SANDER AND SONS. A pretty, pure white *Cattleya* with chrome yellow front to the lip.

Cymbidium Venus (*Holfordianum* × *insigne*), from Messrs. STUART LOW AND CO., Bush Hill Park. Flower of fine shape and substance, and indicating *C. grandiflorum* obtained through *Holfordianum*; white, with very small dark violet spots on the lip.

Miltonia Adonis (*Bleuana* × *M. G. D. Owen*), from Monsieur CHAS. VUYLSTEKE. Flower white, with deep maroon mask to the lip. A very pretty flower.

Odontioda Prince de Galles (*Od. Mirum* × *Oda. Vuylstkeae*), from Monsieur CHAS. VUYLSTEKE. The flower is of the *O. Coronation* class, bluish white, handsomely blotched with red.

CULTURAL COMMENTATION.

To Sir JEREMIAH COLMAN, Bart. (gr. Mr. Collier), for *Odontioda Bradshawiae* Fire King with several spikes of bright scarlet flowers.

To Sir J. COLMAN, Bart., for *Dendrobium Lyonii* with five spikes of rose-coloured and white flowers.

To F. J. O. MONTAGU, Esq., Lynford Hall, Mundford (gr. Mr. E. Hill), for an immense specimen of the white *Cattleya intermedia alba* with 16 spikes, 55 flowers.

Orchid Groups.

The Orchids were arranged along the two ends of the large tent which gave such an expanse of colour at the International Show.

The proportionately narrow staging did not admit of their being arranged to the best advantage, but the skill of the exhibitors in grouping and breaking the line of their groups by carrying the taller plants upward in a conical form went far to meet the difficulty. As usual at great shows there were many prominent exhibits of similar character, but as each group had a different setting the disadvantage of "sameness" was not apparent.

At the entrance of the Hospital end of the tent Messrs. CHARLESWORTH AND CO., Haywards Heath, had a fine group with a frontage of about 70 feet, the exhibits throughout being in splendid vigour and with finely-developed flowers. The middle consisted of a conical arrangement of scarlet *Odontiodas*, with white *Odontoglossum ardentissimum xanthotes*, *Odontioda Charlesworthii*, *O. Zephyr*, *O. Bradshawiae*, the very fine *O. Joan*, *O. Madeline* and *O. Patricia*. On each side at a lower level were the charming *Oncidium pulchellum*, *Vanda teres*, *Phalaenopsis Rimsteadiana* and *P. Stuartiana*, with interesting species, including *Cyrtopodium Andersonii*, *Oncidium monachicum metallicum*, some very fine *Cattleya Skinneri*, *Coelogyne pandurata*, etc. The end portions, made up in sections, were of *Laelio-Cattleyas* and *Brasso-Cattleyas*, the beautiful *L.-C. Fascinator* and *L.-C. Martinetii* showing well beneath the sprays of *Oncidium Marshallianum*. The new *Brasso-Cattleya Princess Elizabeth* was one of the best. Masses of *Miltonia vexillaria* and hybrids raised by Messrs. CHARLESWORTH followed, and the extreme ends were of *Odontoglossums* in every form of colouring known to the genus, arranged with scarlet *Renanthera Imschootiana*. Among the best novelties in the group were *Cattleya Mendelii* White Swan, a clear white of fine shape; *C. Mossiae* Queen Alexandra, a fine white-petalled form; *Odontoglossum crispum* Nell Gwynne, a model white form; *O. Dusky* Monarch, *O. Queen Alexandrina* and *O. l'Agillon* Princess Mary. For other fine Orchids in the group see Awards.

His Grace the Duke of MARLBOROUGH, Blenheim Palace, Woodstock (gr. Mr. Hunter), showed a very tastefully-arranged group, the highest points being of *Renanthera Imschootiana*, *Epidendrum radicans*, etc. At the ends *Cattleya Schröderae* and *C. Mendelii* were grouped in great variety, with white *Phalaenopsis*, brightly-coloured *Masdevallias*, and well-flowered *Cyripediums*. *Laelio-Cattleya Hyeana*, *L.-C. G. S. Ball*, a selection of *Dendrobiums*, including a number of the pure white *D. nobile virginale*, and some fine *Brasso-Cattleyas* were also included. *Dendrobium Dearei*, with its profusion of white flowers, was well shown, and a selection

of *Cyripediums*, *Odontoglossums*, and other showy Orchids were tastefully arranged.

Messrs. SANDER AND SONS, St. Albans and Bruges, had a very extensive and remarkable group, replete with good things effectively arranged. The centre was a mass of soft rose and white colour given by the numerous home-raised specimens of *Miltonia vexillaria*. *M. Bleuana*, *M. Hyeana*, *M. vexillaria Solum*, *M. v. Laelia Sander* (see Awards), *M. v. Dreadnought* and *M. v. Our Princess* were novelties of great beauty and new colouring. On each side were *Laelio-Cattleyas* and *Brasso-Cattleyas*, the most prominent being a large number of *L.-C. Hyeana splendens* divided into two sections, the *Ruby Gem* class showing it as one of the darkest and brightest in colour, and *L.-C. Fascinator* in great variety of tint and good shape. Scarlet and scarlet and white *Odontiodas* were ar-

decorative plant (see Awards). The frontage of rose and white *Trichopilia suavis* and the pure white *T. Backhouseana*, with their large, fragrant blooms, two elevated masses of white *Phalaenopsis*, with bright red *Renanthera Imschootiana*, and the marvellous beauty of the *Miltonia vexillaria* crosses, were prominent features in the group. The variation in the large and beautiful flowers of the last-named was a source of great attraction, especially the primrose-yellow-tinted *M. vexillaria Laelia Sander*, quite a new departure in colour, and florally perfect in every respect. *M. v. Dreadnought* was a very large rose-coloured flower; *M. v. Our Princess*, white with light disc, and intermediate forms of all tints known to the genus, were present. A suggestion of future development was given by Messrs. SANDER'S new type, *Miltonia Isabel Sander* (*Roetzli* × *Hyeana*), a large, white flower with dark mask, some of the little seedlings now

THE CHELSEA SHOW.

FIG. 155.—HYBRID IRIS RAISED FROM A CROSS BETWEEN *I. CHRYSOGRAPHES* × *I. DOUGLASIANA*.

(See p. 364.)

ranged with white *Phalaenopsis*, and at the end masses of *Cattleya Schröderae*, the beautiful var. *Queen Empress*, which won the Davidson Cup, a superb flower, *C. Mendelii* and fine forms of *C. Mossiae* showed well beside the red *Renanthera Imschootiana*. Throughout the group the good quality of the hybrid *Odontoglossums* was noticeable, the size and shape of the blooms being of the best, and some unusual tints were displayed in some of the newer forms. *O. Albion* (*Rossii* × *percutum*) was a pretty novelty of a rare class. The attractive hybrids of *Miltonia Warszewiczii* raised by the firm, which have already secured awards, were present in pans of *Odontonia Laelia Sander*, *O. St. Alban*, *O. Magali Sander*, and others, together with the latest novelty, *O. Roger Sander* (*M. Warszewiczii* × *O. percutum*), a floriferous hybrid of good shape, and, like others of its class, an excellent

flowering being said to have a nearly black centre.

Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, completed the side with a very fine group, in which *Odontoglossums*, *Odontiodas*, *Laelio-Cattleyas*, *Brasso-Cattleyas*, *Miltonias*, and the other great classes flowering at this season were finely represented. White *Phalaenopsis*, *Coelogyne pandurata*, and hybrid *Cyripediums* drooped their graceful sprays over the group.

Brasso-Cattleyas were well displayed, the best novelties being *Brasso-Cattleya Shilliana* (*B.-C. Digbyano-Mossiae* × *C. Mossiae*), shown at the International as a small plant, and figured in the *Horticultural Record*, and *Brasso-Laelio-Cattleya Prince of Wales* (*B.-C. Digbyano-Mossiae* × *L.-C. Dominiana*), a charming flower. The best of a fine lot of crosses of *Miltonia vexillaria Memoria G. D. Owen* were the varieties

Miss Louisa Fowler, J. Gurney Fowler (see Awards), and The Baroness, large flowers with the characteristic chowy mask to the lip. *M. Hyeana* Orchidhurst variety was a beautiful and distinct flower. Of the batch of brilliant red *Odontiodas* the best were *O. Cooksoniae* Orchidhurst variety; three fine forms of *O. Coronation*, *O. Chantecler* var. *Armstrongae* (a

and petals and ruby-tinted lip; *L.-C. Fascinator* *Invincible*, a magnificent plant; and varieties of *L.-C. callistoglossa*. Among the *Miltonias* were the true *M. vexillaria* *Memoria* G. D. Owen, *M. The Marquis*, with large flowers, having a dark mask to the lip, *M. Bleuana*, etc. Others noted were *Oncidium McBeanianum*, *Oncidioda Cooksoniae*, some showy *Masdevallias*

showy *Odontiodas*, *L.-C. Dominiana* with white sepals and petals, and a pretty form of *L.-C. luminosa*. Among *Brassavola* crosses *Brasso-Laelio-Cattleya Hylas* (*B.-L. Digbyano-purpurata* × *C. Aclandiae*) was remarkable, and *Disa Luna* and a good selection of finely foliaged *Anoetochilus* gave a distinguishing character to the group. The gem of the collection was the new *Laelio-Cattleya Medina Excelsior*. (See Awards.)

Mr. C. F. WATERS, Balcombe, came next with a group of *Odontoglossum crispum*, *Cattleya Mossiae*, *C. Mendeli*, *C. Schröderae*, *Lycastes*, *Laelio-Cattleyas*, etc., a representative collection of Orchids for cut flowers and decorative purposes. The plants were finely bloomed, and in small pots.

Messrs. STUART LOW AND Co., Bush Hill Park, and Jarvisbrook, Sussex, completed the side with an extensive and well-arranged group of showy Orchids. Many fine forms of *Cattleya Mossiae*, *C. Mendeli*, and *C. Schröderae* were arranged with tall spikes of red *Renanthera* *Imshoottiana* and white *Odontoglossums*, being very representative of the best decorative Orchids of the season.

Cymbidium Venus (*Holfordianum* × *insigne*) is a charming new hybrid with white flowers of fine shape, the lip having very small violet spots. *Laelio-Cattleya Haroldiana Bronze King* (see Awards) is certainly the most beautiful of this favourite hybrid, and the numerous *Dendrobiums* and other Orchids were well displayed.

Mr. HARRY DIXON, Spencer Park, Wandsworth, showed a group of *Miltonia vexillaria*. His *Cattleya Mossiae* included the bizarre variety *marmorata*. Of *C. Mendeli* one pretty blush form had a white lip. There were also a splendid form of *C. Trianae*, *C. intermedia alba*, and various *Laelio-Cattleyas* and *Odontoglossums*.

Messrs. J. CYPHER AND SONS, Cheltenham, had a very pretty ornamental arrangement of Orchids and foliage plants, in which well-flowered *Dendrobium Wardianum*, *D. Devonianum*, showy *Masdevallias*, *Odontoglossums*, *Cymbidiums*, *Laelio-Cattleyas*, *Calanthe veratrifolia*, and other good things were displayed.

OTHER NOVELTIES.

There were 65 novelties submitted to the Orchid Committee for award, and the best of those not already enumerated are *Brasso-Laelia Madame Irene Mavrocordato Braekenhurst* variety (*L. Iona nigrescens* × *B. Digbyana*); *Odontioda Fowleriana* (*Oda. Bradshawiae* × *Odm. percultum*), a fine flower with white ground heavily marked with dark purple and with light rose front to the lip; and *Oda. Rubens* (*Oda. Charlesworthii* × *Odm. eximium*), with cerise red

THE CHELSEA SHOW.

FIG. 156.—LAELIO-CATTELEYA HAROLDIANA BRONZE KING. (See Orchid Awards.)

deep scarlet of good shape); *O. beechense* (*O. Rolfeae* × *C. Noezliana*), and *O. The Baron*. Among the *Odontoglossums*, *O. hylandianum*, *O. Queen Mary*, *O. Chantecler* and *O. King Emperor* were distinct hybrids of great beauty, the parentages of which are unknown; *O. Aglaon Sandhurst*, a variety richly blotched; and *O. harvengtense* Orchidhurst variety, an excellent yellow-ground hybrid of good shape. Some pretty *Cypripediums*, including a beautiful cross between *C. Fairricanum* and *C. glaucophyllum* and a fine lot of seedling *Odontoglossums*, were included.

Messrs. MANSELL AND HATCHER, Rawdon, Yorkshire, had a fine and artistically-arranged group, the centre of long, white sprays of *Phalaenopsis Rimestadiana* overhanging bright-red *Renanthera Imshoottiana* being one of the best effects in the show. A good selection of *Odontoglossums*, *Miltonias*, *Odontiodas*, *Laelio-Cattleyas*, etc., occupied each side, and the ends were furnished with a large selection of good *Cattleya Mossiae* and *C. Mendeli*, varying considerably in colour, some pretty *Cypripediums*, an interesting selection of *Dendrobiums*, and some uncommon species now seldom seen in show groups.

Messrs. J. AND A. McBEAN, Cooksbridge, had a very fine group, containing a large proportion of plants of extraordinary merit, and especially rich in brightly-coloured *Odontiodas*, including *O. Bradshawiae Perfection*, a great beauty, fine forms of *O. Charlesworthii*, *O. Lambeanum*, *O. Bradshawiae*, *O. Keighleyensis*, *O. Diana*, *O. Euterpe*, and *O. Vuyksteakeae* of the newer dark-coloured strain. The *Odontoglossums* comprised some of the best white forms of *O. crispum* and spotted forms, both imported and home-raised, good *O. illustrissimum*, *O. ardentissimum*, *O. Gladys*, *O. Phoebe* and some pretty new seedlings. The *Cattleyas* were very fine, one good *C. Mossiae* bearing 27 flowers. *C. M. Anak* was very large and beautiful in form; *C. M. aureola* had an almost entirely yellow lip. A good *C. Mendeli*, the white *C. Susanna* *Hye de Crom*, the albino *C. Skinneri*, and other white *Cattleyas* were also noted. Among the *Laelio-Cattleyas* the best were several *L.-C. Helius* (*G. S. Ball* × *Mossiae* *Wageneri*), with clear yellow sepals

and *Dendrobiums*. The *Cattleyas* were remarkable for their enormous pseudo-bulbs and fine flowers. All were examples of the results of good culture.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Surrey (gr. Mr. Collier), showed a beautiful group of the brightly-coloured *Odontiodas* raised at Gatton, some of the plants having five or six spikes of scarlet flowers. Over these were hybrids of *Odontoglossum Edwardii*, and among other beautiful *Odontoglossums* was the handsome *O. crispum* *Pride of Gatton*.

Messrs. FLORY AND BLACK, Orchid Nursery,

THE CHELSEA SHOW.

FIG. 157.—ODONTIODA BRADSHAWIAE PERFECTION. (See Orchid Awards.)

Slough, staged an excellent group of hybrids. At the back were *Odontoglossums*, above *Miltonia vexillaria*, *M. Hyeana*, and *M. Blenana*. In front were some good spotted *Odontoglossums*, one blotched *O. crispum* being spotted with dark chocolate-purple. Specially noteworthy were the forms of *Cattleya Mendeli* and *C. Mossiae*, some

flowers. These three from J. GURNEY FOWLER, Esq.

Miltonia vexillaria alba with large pure white flowers, the best large white yet shown, from W. R. LEE, Esq., Plumpton Hall, Heywood.

Miltonia vexillaria alba, from Monsieur Jules Hye de Crom.

Odontoglossum eximium Boltonii, from J. J. BOLTON, Esq., Pendleton, Manchester. A large flower finely blotched.

Miltonia vexillaria Woburn, a large bright rose-pink; and *M. v. leucoglossa*, from ERNEST MOCATTA, Esq., Woburn Place, Addlestone, Surrey (gr. Mr. Stevenson).

Odontoda Queen Mary Westonbirt variety, from Lieut.-Colonel Sir Geo. L. HOLFORD, K.C.V.O. (gr. Mr. H. G. Alexander). A splendidly-flowered plant, bearing a fine spike of large red flowers, with white spaces between the blotches.

Cypripedium bellatulum R. Ashworth from RICHARD ASHWORTH, Esq., cream-white with vinous red blotches and flush.

Stove Plants.

Messrs. J. VEITCH AND SONS, Chelsea, exhibited four large groups of stove and greenhouse ornamental foliage and flowering plants in the large tent. Two of the groups were composed solely of splendidly-grown *Caladiums*, which bore large, highly-coloured leaves. Very rich colour was supplied by the varieties *Madame E. Pynaert*, *Louis van Houtte* and *Emperor Alexander III.*, whilst the best of the lighter-coloured sorts which have more transparent leaves was a splendid plant of *Rose Laing*. In the other two groups there were miscellaneous collections of the high-class plants which are associated with Messrs. VEITCH. Brilliant foliage colour was supplied by single-stemmed *Codiaeums* (*Crotons*), *Ananassa sativa variegata*, *Bertonia Comte de Kerchove*, and *Dracaenas*, whilst the flowers of the *Crozy Cannas*, of *Kalanchoë flammea*, and the spathes of *Anthuriums* were of tropical brilliance. On tall pillars and draped with sprays of *Asparagus Sprengeri*, the pitchers of *Nepenthes Curtisii superba* and of *N. Mastersiana* excited the interest and admiration of the visitors.

Messrs. JOHN PEED AND SONS, West Norwood, contributed a magnificent collection of *Caladiums*. The many plants were perfect specimens and displayed an almost bewildering variety of colours. A large plant of *Triomphe de Comte* glowed with warm red colouring. The large leaves of *Silver Queen* were of such transparent texture and contained so little green colouring that one wondered how they continued so healthy and flourishing. *King George* is another fascinating variety which bears crumpled leaves of scarlet and green.

Messrs. J. CYPHER AND SONS, Cheltenham, arranged a charming group in the style we have become accustomed to see at the Shrewsbury Show, but at Chelsea we were able to admire it from all sides instead of merely from the front. A light arch spanned the group and supported a spreading *Palm*, yellow-leaved *Crotons*, *Anthuriums* and *Asparagus*. The dominant feature of the plants on the grass was the rich colour of the *Ixoras*, and of *Metrosideros floribunda*. At the corners were circular little groups of such plants as *Erica Cavendishiana*, *E. ventricosa* *magnifica* and *Ixora Williamsii*.

Roses.

Messrs. W. PAUL AND SON, Waltham Cross, showed Roses even better in quality than at the Spring Rose Show. As at Vincent Square the tall pillars bore wonderful displays of beautiful blooms. Of these the very finest were *Sodenia*, *Tausendschön*, *White Tausendschön*, *Delight* and *Hiawatha*. The dwarf Roses included magnificent plants of *Frau Karl Druschki*, Mrs. John Laing, *General MacArthur*, *Dr. William Gordon* and *D. R. Williamson*, each bearing over a dozen blooms, and smaller, but equally vigorous, examples of *Magnolia*, *Souv. de Gustave Prat*, *Viscountess Enfield*, *Margaret* and *Ulrich Brunner*.

Although Messrs. WM. CUTBUSH AND SON, Highgate, employed only cluster Roses in their exhibit, they made an exceedingly charming display. A moss-covered basket, raised 7 feet high, and filled with long, graceful sprays of *Dorothy Perkins*, was poised just above the tall pillars of *Crimson Rambler* which alternated with the pink variety, *Mrs. F. W. Flight*. Other varieties used with good effect were *Ellen Poulsen*, *Joan of Arc*, *Mrs. Cutbush* and *Jessie*.

Messrs. HOBBIES, LTD., Dereham, divided their exhibit of Roses, and made as the central feature

of each group a dainty little pergola completely covered with such Roses as *Dorothy Perkins* and *Lady Godiva*. Outside the pergolas there were large rustic baskets filled with *Polyantha* Roses and vases of exhibition sorts. Of the latter were *Souv. de Gustave Prat*, *Lady Pirrie*, *Marquis de Sinety* and *Countess of Shaftesbury*.

Messrs. PAUL AND SON, Cheshunt, had a wealth of bloom in their group of Roses. The customary tall pillars of *Minnehaha*, *Excelsa*, *Dorothy Perkins* and *Ethel* were placed gracefully above a large variety of well-grown dwarf Roses, chief of which were *Gustave Grunerwald*, *Edward Mawley*, *Rayon d'Or*, *Ulrich Brunner*, *Cherry Ripe*, *Lady Hillingdon* and *Hugh Dickson*. Adjoining the Roses Messrs. PAUL arranged a very bright collection of hybrid *Rhododendrons*.

The group, principally composed of *Wichuraiana* hybrids, arranged by Mr. CHARLES TURNER, Slough, was graceful and attractive. In addition to the usual tall pillars of *Dorothy Perkins*, *Minnehaha* and *Hiawatha* there were weeping standards of *Farquhar* and *Ethel*, and a few standard *Tea* Roses.

Mr. GEORGE PRINCE, Oxford, arranged a group of Roses which was especially rich in the massed

and Mrs. Wemyss Quin (yellow) were presented for Award.

Messrs. R. J. BARNES AND SON, Malvern, exhibited the fine climbing *Rose American Pillar* as a background to specimen blooms in vases, the most conspicuous variety being *Rayon d'Or*, one of the best of all yellow Roses.

Messrs. B. R. CANT AND SONS, Colchester, staged, on a table, a superb exhibit of Roses, the varieties of all types being splendid. At the back were pillar varieties, with flowers falling as though in cascades or hanging in festoons and bunches, *Minnehaha*, *Goldfinch*, *Lady Gay*, *Blush Rambler*, *White Dorothy* being especially good. *Bamboo epergnes* filled with specimen blooms of *Liberty*, *Lady Reay*, *Anna Olivier*, *Hugh Dickson*, *Mme. Edouard Herriot*, *St. Helena*, *Richmond* and *Mrs. John Laing* were equally as attractive as the climbers.

Messrs. FRANK CANT AND CO., Colchester, were the exhibitors of Roses in great numbers and variety. Their standard-trained plants of such varieties as *Delight*, *Jessie*, *White Dorothy*, *Orleans Rose*, *Dorothy Dennison* and others were especially attractive. The ground of the exhibit was comprised of a wealth of most of the popular varieties in cultivation. We noticed

THE CHELSEA SHOW.

FIG. 153.—PRIMULA SECUNDIFLORA.

(See Floral Committee's Awards, p. 364.)

pillars of *Excelsa*, *Dorothy Perkins*, *Lady Godiva*, and *American Pillar*. This profusion of graceful trusses towered above the groundwork of *Mrs. Cutbush*, *Erna Teschendorf*, and such *Teas* and *H.T.* varieties as *Sunburst*, *Richmond*, and *Duchess of Shaftesbury*.

Messrs. STUART LOW AND CO., Bush Hill Park, Enfield, had a small group of Roses near their exhibit of greenhouse shrubs. The predominant feature was a vase of highly-coloured *Mme. Edouard Herriot*, next to vases of *Mrs. John Shawyer* and *Frau Karl Druschki*.

Messrs. GEORGE MOUNT AND SONS, Canterbury, covered the back of their tent space with magnificent clusters of bright red and deep pink Roses. The tall plants of *Excelsa*, *Hiawatha* and *Dorothy Perkins* provided an extraordinary amount of bloom, and formed a splendid foil to the dwarf masses of *Sunburst*, *Gustave Grunerwald*, *Richmond*, *General MacArthur*, *Ulrich Brunner* and a host of equally beautiful and desirable varieties; whilst at each end there were pillars of *Minnehaha* and *Crimson Rambler*.

Messrs. ALEX. DICKSON AND SONS, LTD., Newtownards, Co. Down, exhibited Roses, mostly novelties. The new varieties *Killarney*, *Brilliant* (rose-pink), *Christie Mackellar* (apricot-salmon),

amongst these the beautiful *Mrs. J. H. Welch* (bright rose), *J. J. L. Mock*, *Edward Mawley*, *Viscountess Enfield*, *Mrs. H. Stevens*, *Duchess of Wellington*, *Geo. Dickson*, *Mrs. Muir MacKean*, *Richmond*, *Redhatte* (a beautiful single bedding variety), *Melody*, *Mrs. Foley Hobbs* and *Lady Ursula*.

Mr. ELISHA J. HICKS, Hurst, Berkshire, showed a group containing the new *H.T.* *Mrs. Edward Alford*; the flower is pink, and it was the feature of the stand. There were also choice blooms of *Richmond*, *Lady Hillingdon*, *Sunburst*, *Mrs. Geo. Shawyer* and *Mrs. Chas. Reid*.

Messrs. G. AND W. H. BRUCH, Peterborough, also showed Roses in variety.

Carnations.

Mr. C. ENGELMANN, Saffron Walden, set up tall stands filled with fragrant Carnations, and also draped the back and end of his tent space with fine blooms. The large vase of the orange-buff *Electra* just behind a dozen splendid blooms of *Scarlet Carola* and flanked by *Snow-storm*, provided a centre to the group. The tall stands contained *Enchantress*, *Sunstar*, *Queen Alexandra* and *Scarlet Glow*. Amongst the front row varieties *Rose-pink Enchantress*, *Harlequin*,

Rose Dorée, and a seedling were especially prominent.

Messrs. ALLWOOD BROS., Haywards Heath, covered a tall centre-piece with an enviable profusion of the deliciously-scented Carnation Mary Allwood. This, crowned with a perfect specimen of Phoenix Roeblinii, below which hung vases of especially good May Day Carnations, was very delightful. Other varieties which evidenced equally skilful culture were Carola, in intense colour; Wivelsfield White, in unusually good form and purity; and Baroness de Brien.

Messrs. YOUNG AND Co., Hatherley, Cheltenham, also exhibited a collection of well-grown Carnations. The centre stand of Mikado and Cecilia was a daring experiment in colour combination, but it was not unpleasing. The body of the group was composed chiefly of tall stands of such varieties as Hon. Lady Neeld, Rose Enchantress, May Day, Scarlet Glow and Carola.

THE CHELSEA SHOW.

FIG. 159 — SWEET PEA FRILLED PINK, ONE OF THE BEST OF THE NEWER VARIETIES.

Mr. A. F. DUTTON, Iyer, Bucks, showed many fresh and good Carnations in vases. The principal varieties were Winsor, Mrs. C. F. Raphael, Chelsea (a new variety in which the white ground is striped with pink), Triumph and Mikado.

Messrs. WM. CUTRUSH AND SON, Highgate, had

a very elegant group of cut Carnations, in which the perpetual-flowering Malmaison hybrids were the chief feature, but there were also many vases of delightful blooms of Carola, May Day, Pink Enchantress and Mary Allwood in this very artistic display.

Mr. JAMES DOUGLAS, Edenside, Great Bookham, staged Auriculas and border Carnations. This splendid exhibit was representative of the best varieties of these florists' flowers. Of Carnations we remarked Hercules (Clove), Renown, Rosy Morn (rose), Kate Nickleby (white), Jean Douglas (scarlet) and Mrs. Robt. Gordon (pink).

Messrs. STUART LOW AND Co., Enfield, showed baskets of blooms suspended overhead. The varieties Mrs. C. F. Raphael, cherry red; Baroness de Brien; Salmon King and Satin Robe are a selection. In the large tent Messrs. STUART LOW AND Co. exhibited a circular group of pot plants, chiefly of the hybrid perpetual and Malmaison varieties.

Mr. BERTIE E. BELL, Castle Nursery, Guernsey, showed varieties of perpetual-flowering Carnations. A seedling of darker pink colour than Empire Day is a very promising variety. Perpetual-flowering Carnations were also ex-

hibited by Mr. E. J. WOOTTEN, Eastleigh, Hampshire, and Mr. H. BURNETT, Guernsey.

Begonias.

Messrs. BLACKMORE AND LANGDON, Bath, brought magnificent double-flowered tuberous Begonias. All the plants were models of cultural skill, and bore huge round blooms of Camellia-like proportions, but without exhibiting the slightest trace of coarseness. The range of colours was very great, but perhaps the most noteworthy shades were the rich golden and orange yellows and the deep crimson. A series of Begonias of pendulous habit placed on stands added grace and lightness to this splendid exhibit.

Messrs. T. S. WARE, LTD., Feltham, showed superb Begonias of the tuberous-rooted section. In the front was a bank of the fine King George V. variety, the plants having up to a dozen beautiful orange-salmon coloured flowers, with crimped petals. Other varieties that were specially notable were Lady Cromer, Lady Sarah Wilson soft salmon blush; Thomas Rooney, white; and Lady Gladstone, yellow.

Mr. A. L. GWILLIM, Sidecup, Kent, exhibited a group in which the wide range of beautiful colours, the large imposing flowers, and the general fine quality of the plants stamped the exhibit as one of much excellence.

Pelargoniums.

The dazzling brilliancy of the bedding Pelargoniums arranged in a circular group by Messrs. H. J. JONES, LTD., Ryecroft, Lewisham, overpowered several of the other exhibits, and made them appear almost dowdy. Particularly noteworthy were Pink Pearl, a variety which will undoubtedly be as popular a pink as Paul Crampel is amongst the scarlets, and a white seedling. Many of the plants shown were in three-inch pots, and each of them bore trusses fully six inches across, whilst the larger plants were proportionately floriferous.

Messrs. GODFREY AND SON, Exmouth, Devon, showed a splendid collection of fancy, show and scented Pelargoniums. The show and fancy varieties were of very sturdy habits, and bore large trusses of rich blooms.

Mr. PHILIP LADDS, Swanley Junction, displayed bedding Pelargoniums in a "flower bed" which was edged with Ageratum and lightened by pyramid Fuchsias. The varieties Elsie Ladds, Captain Flayelle, and Maxime Kovaleski were of superior merit to some of those used for summer bedding.

Messrs. H. CANNELL AND SONS, Eynsford, exhibited plants of show and bunches of Zonal Pelargoniums; also pyramidal plants of blue, white, and pink Myosotis, charming little specimens in pots.

Varieties of Zonal Pelargoniums were displayed by Mr. VINCENT SLADE, Taunton.

Uncommonly well-flowered Pelargoniums of the show and Regal types were exhibited by Mr. P. BRANDT, Esq., Bletchingley Castle, Surrey (gr. Mr. J. W. Burks). This exhibitor also showed a fine strain of Streptocarpus.

Mr. A. H. COLE, Swanley, Kent, showed fancy Pelargoniums and a good strain of greenhouse Calceolarias with the yellow-flowered C. Clibranii at the back.

Sweet Peas.

Messrs. DOBBIE AND Co., Edinburgh and Marks Tey, exhibited thirty-six varieties of Sweet Peas, the blooms being the finest in the show. The long, stout stems bore three and four large, fresh flowers of clear colours. The chief of the pink-flowered varieties were Frilled Pink (see fig. 159), Duchess of Portland, Norma, Audrey Crier and Doris Usher; of the whites Elsie Herbert, King White and Etta Dyke were especially pure; whilst of the blush-whites Elsie Herbert was the very best. Amongst the darker shades of colour Dobbie's Orange and Dobbie's Scarlet were very prominent.

Messrs. SUTTON AND SONS showed a representative collection adjoining their exhibit of vegetables. Edrom Beauty, Royal Rose, Barbara, Orange Perfection, Thos. Stevenson and Doris Usher are a few of the more noticeable varieties.

Messrs. E. W. KING AND Co., Coggeshall, Essex, showed a dainty exhibit. A gallery at the back was furnished with big

epergnes of the varieties James Box, Kathleen, R. F. Felton and Inspector. Other varieties shown well were Anglican, Royalty (new, maroon), Lavender Geo. Herbert, Morning Mist (new, faint crimson blush), Anglican Brilliant (rose) and Anglican Orange.

ROBERT SYDENHAM, LTD., Birmingham, showed the beautiful orange-coloured variety Robert Sydenham, and there were also good vases of Rosabelle, Princess Mary (pale blue), Edrom Beauty and other varieties.

Mr. J. STEVENSON, Wimborne, showed a selection of most of the best varieties in cultivation.

Messrs. R. H. BATH, LTD., Wisbech, showed a small but choice collection. The vases of Thos. Stevenson, Glow, Agricola and Florence Wright Spencer attracted special notice.

Mr. J. D. WEBSTER, Chichester, exhibited Sweet Peas, Carnations and Spanish Irises.

Messrs. S. BIDE AND SONS, Farnham, made a dainty exhibit; the vases were staged on a white ground beneath a canopy of white drapery. Their novelty, Phyllis Bide (orange-salmon), was afforded a conspicuous place in the collection.

Sweet Peas were also exhibited by Mr. JAMES AGATE, Havant.

Tulips.

Fifteen collections of May-flowering Tulips were shown. The Darwins predominated, and the various collections naturally showed a great deal of duplication. Distinction was found mainly in tasteful arrangement as in the case of Messrs. SUTTON, in novelty of arrangement as in the design of Messrs. DICKSON AND ROBINSON, or in quality of blooms.

Messrs. SUTTON AND SONS, Reading, showed tastefully against black velvet a small collection of the best sorts. The blooms were of specially fine quality. Plutarch, Mahony, Turenne, Dom Pedro and other Breeders were notable for their large size.

Messrs. R. AND G. CUTHBERT, Southgate, N., had some very fine flowers, among which Le Petit Blondin, Ouida, Giant, Duchess of Westminster, and King Harold stood out well among the Darwins.

Messrs. HOGG AND ROBERTSON, LTD., Dublin, gave character to their group by their fine Cottage varieties. Queen Alexandra is a Darwin-shaped yellow, shaded outside lightly with bronze when young. Doris is one of a little group remarkable for its art shades of rose on yellow.

Messrs. A. DICKSON AND SON, Newtownards, showed one of the largest, and at the same time choicest, collections, using small pails to hold the very large bunches by which most of the varieties were represented. The varieties Clara Butt, Melicette, Sophrosyne, Chameleon, and Princess Juliana were notably good.

Mr. A. DAWKINS, King's Road, Chelsea, staged a useful collection of Darwins, including the varieties Duchess of Westminster and Purple Perfection.

Mr. C. BOURNE, Simpson, Bletchley, staged prettily against a grey background a number of good sorts. We were especially impressed by Louis XIV. and Zulu, whilst Inglescombe Yellow and Velvet King stood out well.

Mr. W. A. WATTS, St. Asaph, showed some good flowers, but the arrangement of tall columns much overtopping the baize background was unsatisfactory. The varieties Dal Ongaro, Ellen Willmott, Clara Butt and Gustave Dore were noted as good.

Messrs. R. WALLACE AND Co., Colchester, arranged a large group in a scheme of soft shades, including Inglescombe Yellow, Massenet Lantern, Beauty of Bath and Boadicea, with a touch of purple from the self-coloured Fashion.

Messrs. WATERER, SONS AND CRISP, LTD., also staged a collection on tabling. The varieties La Tulipe Noire, Mareoni, King Harold, Duke of Edinburgh and Turenne were well shown.

Messrs. DICKSON AND ROBINSON, Manchester, carried out a scheme of planting in formal beds of varying shape on the ground. Thus, Rawenhoff and Whistler in one bed were used over Veronica diosmifolia, La Tristesse was over Phlox canadensis, Jaume d'Oeuf over pink Thrift, and Gesneriana spathulata was mixed with Columbines. The experiment was worth trying, but on the whole the combinations were rather disappointing in such small plots.

Messrs. DOBBIE AND Co., Marks Tey, staged a large batch of good flowers. Bartigon, La

Tulipe Noire, Rev. H. Ewbank, Walter T. Ware and some specially fine blooms of Inglescombe Yellow were conspicuous.

Messrs. R. H. BATH, LTD., Wisbech, had two square-based pyramids on the ground in the big tent, edged with Violas and brightened by the clear blues of Scillas. The fine variety Clara Butt formed a pleasing centrepiece, and Louis XIV., Edmée and Salmon King were also good. Many of the blooms, however, were on the small side.

Messrs. BARR AND SONS, Covent Garden, showed one of the richest and most effective collections, arranged in two large square plots. They included the best collection of Breeders and the only Florists' varieties. Rose Hill (crimson-rose) and Music (purple) were espe-

cially good. No matter whether the plants were dwarf bushes or tall, clean-stemmed standards, all were covered with deliciously-fragrant blooms. The range of colour was surprisingly great—rich warm pinks, orange and orange-scarlets, and the pale blush pinks, as well as pure white, all provided a wealth of rich colouring and fragrance.

Messrs. WATERER, SON AND CRISP, LTD., Liverpool Street, London, exhibited three beds of gorgeous Rhododendrons. In one a large breadth of the popular variety Pink Pearl attracted attention, and enhanced the rich reds of Doncaster, Charlie Waterer, and Frederick Waterer. In the opposite bed the new variety, Alice, similar to Pink Pearl, but of a deeper pink and slightly smaller trusses, glowed with

THE CHELSEA SHOW.

FIG. 160.—CAMPANULA TOMENTOSA MAUD LANDALE.

cially good. Of the Darwins we were struck by the beauty of Sophrosyne and Ronald Gunn.

Messrs. CARTWRIGHT AND GOODWIN, LTD., Kidderminster, designed a pleasing arrangement on the ground with a central pyramid leading to lesser domes of flowers at the corners of the group. The deep mahogany-coloured André Doria, Baronne de la Tommaye and Suzon were notably good.

Messrs. JEFFERIES AND SON, LTD., Cirencester, showed Geefs, Ouida, Blue Bird, Ant. Roozen and other good Darwins on the floor of the big tent.

Rhododendrons and Azaleas.

Messrs. R. AND G. CUTHBERT, Southgate, massed Ghent Azaleas in a charming profusion

warm colouring, and was a delightful foil to such pale sorts as Gomer Waterer, Delicatissimum, and Lady Clementina Walsh. In corners of the beds batches of Corona, a charming coral red variety, were particularly charming.

Mr. G. REUTHE, Keston, Kent, included several uncommon Rhododendrons in his groups of hardy plants. The chief Rhododendrons were R. Falconeri, bearing large trusses of delicate flowers, R. Roylei, with almost cinnamon yellow blooms, R. Dalhousiei, and R. Thomsonii. Other notable items were vases of Magnolia Watsonii, and of Anopterus glandulosus.

Messrs. FLETCHER BROS., Chertsey, Surrey, showed groups of well-grown Rhododendrons, of which Mrs. John Waterer, Prometheus, Kate Waterer, and W. E. Gladstone amongst the

dwarf bushes were especially noteworthy. The standards of Pink Pearl, Cynthia, Lady Grey, Egerton and other sorts, were also of more than ordinary quality.

Although the popularity of trained plants has waned in this country, the excellent examples of *Azalea indica* and varieties shown by Mr. CHARLES TURNER attracted a great deal of admiration, and revived old memories.

MESSRS. J. VEITCH AND SONS filled a circular space with dwarf and standard Azaleas. This exhibit was noteworthy for the mass of colour; but the *Azalea indica* varieties are not suitable plants for the style of arrangement adopted.

MESSRS. VEITCH also had an imposing group of hardy flowering shrubs. Hybrid Rhododendrons, Ghent Azaleas and Clematis predominated; and of the first-named the bushes of Pink Pearl bore very large trusses of rich colour.

Flowering Shrubs.

MESSRS. J. PIPER AND SONS, Bishops Road, Bayswater, used the space around the Obelisk and its base for a floral display. Around the lower portion of the plinth they massed panels of *Azalea amoena* with cornices of *Acer negundo* variegata, whilst on a platform around the base were displayed a large number of miniature

were many colour varieties and a double-flowered form.

Brooms in a great variety were the outstanding feature of the group of shrubs displayed by Mr. R. C. NOTCUTT, Woodbridge. Amongst these *Cytisus purpureus incarnatus*, *C. Butterfly*, *C. Daisy Hill*, *C. Beanii*, and *C. purpureus alba* were very beautiful.

Near to their beautiful Rose exhibit Messrs. WM. CUTBUSH AND SON had an equally admirable group of hardy flowering shrubs. Here Hydrangeas were the dominant feature, and they harmonised well with the secondary batches of Pink Pearl Rhododendrons, of *Cytisus Andreanus*, and the Mollis Azaleas.

MESSRS. W. PAUL AND SON, Waltham Cross, included several little groups of *Pyrus angustifolia* fl. pl., a variety which bears large and very fragrant flowers, in their exhibit of hardy flowering shrubs. *Jasminum revolutum*, *Cistus purpureus*, *Rubus deliciosus*, various Rhododendrons, and Clematises in an interesting collection of shrubs.

Mr. CHAS. TURNER, Slough, showed exceptionally fine bushes of Lilacs, chiefly of such double-flowered sorts as Charles Sargent, Mme. Casimir Périér, Mme. Lemoine and Charles Joly.

Mr. L. R. RUSSELL, Richmond, exhibited a

palmatifidum represented the section with finely-divided leaves.

The DONALD NURSERY CO., Newcastle, County Down, Ireland, had splendid bushes of the red-flowered *Leptospermum bullatum Nichollii* and the pink variety *Chapmanii* in their group of uncommon trees and shrubs. Other valuable species were *Tricuspidaria lanceolata*, *Enkianthus cernuus*, *Pittosporum Tobira variegata*, *Olearia Gunnii* and *Myrtus bullata*.

Mr. C. W. CHANTLER, St. Mary Cray, Kent, showed Conifers, Ghent Azaleas, and other hardy shrubs.

MESSRS. W. AND J. BROWN, Peterborough, displayed a large group of Lilac bushes bearing large trusses of fragrant flower. A new Heliotrope, named The Speaker, was included in the exhibit.

Ferns.

MESSRS. H. B. MAY AND SONS, Upper Edmonton, exhibited magnificent stove and greenhouse Ferns in a great variety. A dozen or more perfect plants of *Nephrolepis Willmottae*, each as dense as woodland moss and of fascinating pale-green colour, relieved by graceful little pillars of the "Climbing Fern" (*Lygodium japonicum*), formed a charming feature.

Towards the other end of this monster collection, a magnificent specimen of *Davallia solida superba* was equally delightful in richer, darker green. Colour is not usually associated with Ferns; one's mental impression of these plants is that of fronds of cool graceful green in a great variety of form, but Messrs. MAY always introduce bright colour—much brighter than would be expected—in their exhibits. *Gymnogrammas* of gold and silver hue, the reddish-purple young fronds of *Osmunda palustris*, *Adiantum Veitchii* and *A. macrophyllum* were very bright and attractive; whilst bronzy-red was supplied by the graceful trails of *Selaginella caesia* and the erect, fertile fronds of such *Osmundas* as *regalis purpurascens* and *japonica furcans*.

MESSRS. J. HILL AND SON, Lower Edmonton, exhibited a large bank of stove and greenhouse Ferns, arranged with great skill and taste. Tall tree Ferns (*Cyathea dealbata* and *Hemitelia Smithii*) spread their long, graceful fronds over the dwarfier species. Of these latter *Gymnogramma elegantissima*, *Polypodium Mandianum*, *Davallia Fijiensis elegans*, *Gleichenia rupestris glaucescens* and *Microlepia hirta cristata* were shown as large and exceedingly well-grown plants, which were characterised by healthy green fronds.

Mr. AMOS PERRY, Enfield, arranged in the Lime Avenue the only representative collection of hardy Ferns in the show. Some of the plants were specially fine specimens, and among those particularly admired we noted the forms of *Polystichum angulare* named *decompositum*, *longipinnatum* and *grande*; and *Athyrium filix femina todeoides* and *plumosum axminsterense*. An effective touch was given to the whole by the bolder clumps of foliage provided by *Funkias* in the foreground.

Hardy Flowering Plants.

More than fifty exhibits of herbaceous and Alpine plants were staged under canvas. The largest groups found place on the ground in the big tent, but the majority were on staging in the special tabling tent to the east of the tent which contained the sundries. A few groups were exceptionally fine, but, on the whole, the quality and the methods of staging were a little disappointing. There was too much flat banking of flowers and much too frequent evidence that nurserymen were endeavouring to show a little of everything, in season or out of season, so long as it could be induced to give a touch of flower-colour. There is need for more specialisation. Good examples of such specialisation were the Primulas of Dr. McWATT and LISSADELL, the new Chinese plants of MESSRS. BEES, LTD., the Delphiniums of BLACKMORE AND LANGDON, MESSRS. R. WALLACE AND Co.'s Lilies, MESSRS. GUNN AND SON'S Phloxes, and Mrs. LLOYD EDWARD'S mossy Saxifrages; but there is room for a much further development of it.

Sir EVERARD HAMBRO, Hayes Place, Kent (gr. Mr. J. Grandfield), sent a magnificent collection of pot-grown Alpines which was quite un-

THE CHELSEA SHOW.

FIG. 161.—ROCK GARDEN EXHIBITED BY MESSRS. WALLACE AND CO.

rock gardens, dwarf plants of Tree Paeonies, pigmy Cypresses, Hydrangeas, and many Tulips and other cut flowers.

MESSRS. GEORGE JACKMAN AND SON, Woking, displayed a magnificent collection of Clematis which bore exceptionally large flowers of superb quality. Of the double-flowered sorts Belle of Woking and Duchess of Edinburgh were magnificent. The very best of the singles were Crimson King, Impératrice, King Edward VII., King George V., Lasnrstern, Mrs. Spencer, Castle, and Sensation. Messrs. JACKMAN also displayed very valuable late spring flowering shrubs in a large group. Besides floriferous bushes of Weigelas, Kalmias, Spiraeas, Philadelphuses, and various Rhododendrons, there were neat examples of *Ledum latifolium*, *Andromeda speciosa*, *Cistus ladanifera*, *Vaccinium pennsylvanicum*, and several Japanese Maples of bright colour.

MESSRS. J. PIPER AND SONS, Bishops Road, Bayswater, exhibited three large groups of Wisterias. Many of these standards, which were imported from Japan and were growing in the native vases, were apparently of very great age, and it was interesting to note the revivifying influence of grafting young shoots on the old stocks. From these gnarled old trunks long vigorous racemes of charming flowers hung in great profusion. Besides the common species (*W. sinensis* and *W. multijuga*) there

very large collection of hardy shrubs. The excellent Ivies for which Mr. RUSSELL is justly noted were shown fully as well as in former years, and embraced a surprising number of distinct varieties. Japanese Maples of good shape and in diverse forms and colours, many Vitises, of value for furnishing pergolas, pillars, walls, etc., standard Brooms, grafted with the pendulous forms, and several species of *Ceanothus* were also included in this splendid group. In another part of the grounds Mr. RUSSELL massed with great effect a large collection of Ghent Azaleas. Mr. RUSSELL also showed a variety of hybrid Clematis and a few plants of *C. montana rubens*. The most attractive of the hybrids were Nelly Moser, Lady Londesborough, The Queen, Edouard Desfosse, and President. Adjoining the Clematis a very creditable group of *Caladiums* made a bright and attractive display.

MESSRS. FROMOW AND SONS, Chiswick, Middlesex, arranged very many Japanese Maples outside the opposite end of the large tent. Here was displayed a very interesting assortment of these ornamental shrubs. Of those with golden leaves *Acer japonica aurea* was exceedingly well coloured. Bright red colour was supplied by *Acer pulmatum atropurpureum*, and delicate rose by neat bushes of *A. p. roseum* and *A. p. corallinum*, whilst such sorts as *A. dissectum*

rivalled, whether from the point of view of fine culture or rich variety. *Saxifraga pyramidalis*, *longifolia* and *latifolia*, *Grandfieldii* and other encrusted *Saxifragas* formed a too strongly emphasised feathery mass of white to screen the harsher colours of Azaleas at the back; but the gems were "on the line," or "in front." *Erinacea pungens*, a mass of lavender flowers. *Pentstemon Davidsonii*, *Asperula Athoa*, *Haberlea Ferdinandii-Coburgii*, *Dianthus callizonus* and *Jankae Heldreichii* formed special points in which interest focussed.

Mr. AMOS PERRY, Enfield, arranged a good group on the ground with well-proportioned masses of tree *Paeonies*, German *Irises*, and the Oriental *Poppies* in which he specialises. The silvery-white of Perry's White was the most notable of these—a large showy flower with crimson-black basal blotches.

Messrs. T. S. WARE, LTD., Feltham, staged a large, but rather formal, bank of good flowers; *Antirrhinums*, *Paeonies*, *Pyrethrums* and *Eremuri* were the principal plants represented.

Mr. JAMES BOX, Lindfield, showed a pretty group in which the fine plants of *Lilium canadense* and *L. Grayi* were, perhaps, the best features. The *Anchusas* in the wings gave force to the yellows and buffs of *Trollius* and *Verbascum*. *Azalea rosaeflora* was a notable plant, and *Cypripediums* were well represented.

Messrs. G. GIBSON AND Co., Leeming Bar, Bedale, showed hardy border flowers in a square-based pyramid: too solid and flat-faced to be effective. Alpines lined the base. *Thalictrums*, *Lupins*, *Astilbes*, etc., formed the walls, which were crowned at the top with *Verbascums*.

Messrs. BLACKMORE AND LANGDON, Bath, showed an admirable, though small, batch of *Delphiniums*. Yard-long spikes of the soft lilac *Statuaire Rude* formed the centrepiece, while a dark purple-blue band of *Rev. Lascelles*, W. T. Ware, and R. Cox led to the front row plants or *Moerheimii* and other varieties of *Belladonna* type.

Messrs. G. BUNYARD AND Co., LTD., Maidstone, made effective use of *Lilium longiflorum* over *Astilbe Ceres*, and there were good masses of *Pyrethrums*, *Irises*, *Verbascums* and *Eremuri*.

Messrs. CARTER, PAGE AND Co., London Wall, showed annuals, *Paeony*-flowered *Dahlias* and *Violas* in variety.

Messrs. BEES, LTD., Liverpool, made a valuable exhibit of the best things that we owe to the Chinese collections of Forrest. *Primula secundiflora* (see fig. 153), *Roscoea cantaloides*, *Incarvillea brevipes* and the dwarf silver-leaved *Potentilla fruticosa nana argentea*, which is new, stood out as conspicuously good. These, alas! were arranged on a cork rockery!

Messrs. GUNN AND SONS, Olton, showed fine plants, 3 to 4 feet high, of a few of the best varieties of *Phlox decussata*.

Messrs. BARR AND SONS, Taplow, exhibited a floor group. Columns of *Anchusa* occupied the four corners, and led up to a central mass topped with yellow *Tree Lupins*, *Sparaxis*, *Irises*, *Ixias*, early *Gladioli*, and similar plants.

Messrs. W. CUTBUSH AND SON, Highgate, introduced into a ground group a little streamlet, which provided good places for masses of *Trilium*, *Primula pulverulenta* and other water-loving plants. Spanish *Irises*, *Arum Dracunculoides* and *Spiraea Aruncus Knuffii* showed the varied character of the collection.

Messrs. JACKMAN AND SONS, Woking, had a prettily-arranged square-based pyramid of hardy flowers. The brilliant yellows of *Verbascum densiflorum* and *Isatis glauca* brightened the pale blues of the *Delphiniums*. *Lupin* hybrids formed an interesting corner-piece, and *Lilium umbellatum erectum* was boldly massed.

Mr. JOHN FORBES, Hawick, showed *Violas* and *Delphiniums*.

Messrs. W. WELLS, LTD., Merstham, showed a striking mass of the fine pink-coloured *Antirrhinum Nelrose*.

The IGHTHAM ALPINE NURSERY, Ightham, Kent, showed a small batch of Alpines in which the fine masses of the tiny *Viola Slieve Donard* was a centre of attraction.

The BURTON HARDY PLANT NURSERIES, Christchurch, Hants, staged a small, but interesting, collection of Alpines. *Dianthus alpinus albus* and *Mertensia echioides* were its gems.

Messrs. HARKNESS AND SONS, Bedale, York-

shire, showed International and other new *Verbascums* in a square ground plot, with a fine strain of Iceland *Poppies* and other hardy flowers.

Messrs. R. WALLACE AND Co., Colchester, showed a unique collection of *Lilies*. Its best features were *L. regale*, *L. davuricum luteum*, *L. dalmaticum*, *L. Szovitzianum* (a difficult *Lily* to force well), *L. Martagon album*, *L. tenuifolium Golden Gleam* and *L. Kramerii*, but in all some twenty species and varieties were included, and a more representative batch has never been shown at a spring show. Japanese *Maples* formed a pleasing foil. *Eremuri*, *Irises*, etc., gave a touch of variety to a very pretty decorative scheme.

Messrs. PHILLIPS AND TAYLOR, Lily Hill Nurseries, Bracknell, designed a little oblong water garden to give point to their exhibit of *Trollius*, *Primula*, *Astilbe*, *Orontium* and other moisture-loving plants.

Messrs. ARTINDALE AND SON, Nether Green, Sheffield, showed a grand plant of *Tree-Paeony Louis Mouchelet*, with *Eremuri*, *Primulas*, *Violas*, etc.

Messrs. REAMSBOTTOM AND Co., Geashill, King's Co., showed *Anemones*.

Mr. REG PRICHARD, West Moors, Wimborne.

Mr. W. LAWRENSON, Yarm-on-Tees, made a feature of the *Yarn* hybrid between *Primula pulverulenta* and *Primula Cockburniana*.

Messrs. J. VEITCH AND SONS, Chelsea, showed an interesting batch of *Primulas*, of which, perhaps, *P. japonica alba Unique* and *P. pulverulenta Mrs. Berkeley* were the more noteworthy.

Messrs. LISSADELL, Sligo, show a pretty series of *Primula* hybrids in which *Beesiana*, *pulverulenta*, *Bulleyana* and *Cockburniana* influences are shown. The richest scarlet was *Red Hugh*. The varieties *Asthore* and *Alannah* were pretty shades of salmon-pink. With these were fine plants of the rare species *P. deorum*, *P. Forrestii*, *P. longiflora* and *P. muscarioides*.

Dr. MACWATT, Morelands, Duns, exhibited a unique collection of *Primulas*. A catalogue of them would be interesting, but we can only mention the little known *P. Gambeliana*, *P. Wardii*, *P. elongata*, *P. Littoriana*, *P. heucherifolia* and *P. Giraldiana* among a host of better known species and garden forms.

Messrs. WHITELEGG AND PAGE, Chislehurst, made one of the most pleasing small rockwork exhibits under canvas, but their best plants were shown out of doors.

Messrs. KELWAY AND SON, Langport, exhibited several pretty new *Pyrethrums*, with a selection

THE CHELSEA SHOW.

FIG. 162.—MESSRS. R. AND G. CUTHBERT'S EXHIBIT OF RHODODENDRONS.

gave an example of the interest that can be concentrated in even so small a space as four feet of tabling. His group was a collection of little gems, of which *Phlox Douglasii*, *Tanakaia radicans*, *Roseda sesamoides*, *Sedum pilosum*, *Asperula suberosa* and *Galium olympicum* are but a few.

The KING'S ACRE NURSERIES showed a few Alpines on tabling, of which *Tiarella unifoliata* best deserves mention.

Mr. STUART MAILLES, Stevenage, staged *Globularia trichosantha*, *Silene Hookeri*, *Campanula Allioni* and other choice plants in a little piece of rockwork.

Mr. VERNON T. HILL, Mendip Nurseries, Bristol, included such good plants as *Alyssum spinosum roseum*, *Lithospermum graminifolium*, *Sedum pilosum*, *Veronica E. C. Howell* and forms of *Linaria alpina*.

Messrs. G. AND A. CLARK, LTD., Dover, showed a collection of border plants in which the eye was at once caught by the brilliance of the *Pyrethrums* and the good clumps of *Iris* and *Eremurus*.

Messrs. THOMSON AND CHARMAN, Bushey, staged a small collection of rock and moraine plants, *Lewisias*, the *Warley Aethionema* and others. *Thunbergia Gibsonii* was also included in the collection.

of the best *Delphiniums*. *Anchusa italica Mrs. J. Kelway* is a name they have given to the true "opal"-coloured variety which seems to have occurred in several gardens now.

Mr. WM. ICETON, Putney, displayed a large group of *Lily-of-the-Valley* and *Palms*. The *Convallarias* bore unusually large spikes of pure white flowers.

Messrs. GILBERT AND SON, Dyke, Bourne, Lincolnshire, showed their well-known strain of *Anemones*.

Messrs. BACKHOUSE AND SON, LTD., York, arranged a number of delightful Alpines in a small but prettily arranged piece of rockwork. The *Ramondia*, *Haberlea*, *Onosma* and *Dianthus* merited special notice.

Mrs. LLOYD EDWARDS, Bryn Verog, Llangollen, showed seedling mossy *Saxifragas* and *Aubrietias*.

Messrs. J. COCKER AND SONS, Aberdeen, had an especially good batch of *Anemone sulphurea* with *Aquilegia glandulosa* and the newer *Globe-flowers*.

Messrs. RICH AND Co., Bath, showed a collection of *Pyrethrums* with *Geums* and other hardy plants, but the plant that pleased us most was the old-fashioned little *Viola Jackanapes*.

Messrs. FRED SMITH AND Co., Woodbridge, Suffolk, arranged Eremuri, Lupines and other herbaceous flowers over a foreground of Alpines.

Messrs. B. LADHAMS, LTD., Southampton, had the only good collection of Heucheras we noticed in the show, with a mass of *Thalictrum aquilegifolium superbum* and other hardy plants.

Mr. FRANK LILLEY, St. Peter's, Guernsey, had the best collection of early-flowering bulbs—*Sparaxis*, *Ixia*, *Broadiaea*, etc.—with a centre-piece of the noble *Watsonia coccinea*, and patches of the lovely little Peacock Iris which we have come to look for in his exhibits now, so regularly does he show it well.

Mr. G. W. MILLER, Clarkson Nurseries, Wisbech, showed the double *Pyrethrum Queen Mary*, with batches of Harkness' new hybrid *Verbascums*, *Lady Alison*, *Imperial*, etc. The unblotched *Papaver Princess Ena* was another pretty feature.

Mr. T. R. HAYES, Keswick, showed a collection of rock plants. *Polemonium carneum* is uncommon, and we noticed a good form of *Lychnis alpina*.

Mr. E. C. BOWELL, Cheltenham, exhibited a small bank of Alpines, principally *Saxifrages* and *Primulas*, with patches of *Viola* and *Linaria*.

Mr. H. HEMSLEY, Crawley, showed his hybrid Alpine *Antirrhinums*, with *Matthiola*

Mr. WOOD achieved such admirable results last year. Excavation was not allowed, but 300 tons of soil were brought in to make up the banks, and the total amount of stone employed must have exceeded that weight.

Nothing was so keenly looked forward to as the award of the *Daily Graphic* Cup. This is a beautifully proportioned trophy, valued at 75 guineas, which the proprietors of the *Daily Graphic* have presented to the society to be awarded annually in open competition for the best rock garden, judged not from the point of view of size, but for the natural artistic grouping of the stones, for evidence of design in construction and for suitability to the growth of Alpine plants. The rarity or otherwise of the plants themselves was to carry but little weight. The special judges appointed for this class were Mr. Alfred Parsons, R.A., as an artist; Sir Frank Crisp, as an owner of a rock garden; and Mr. E. A. Bowles, as "a gentleman accustomed to the planting of rockwork."

Starting from the main entrance on the Embankment, we treat of the gardens in the order in which they occur. Of the best groups we cannot say that they were better than last year. They seem to have reached a point beyond which a nearer approach to the actual and to nature is impossible. But the average of the exhibits was much higher than at any preceding show, and it

Mr. REUTHE, Keston, used the Cheddar stone, but failed to gain any connected effect with its arrangement of it and his plants, although many good and rare specimens were included. *Androsace pyrenaica* and *A. helvetica*, *Plantago nivalis*, *Olearia Lyalli* and *Helichrysum frigidum* were notable.

Messrs. R. TUCKER AND SONS, Brookside Nurseries, Oxford, were placed in a square plot on one level. They broke this up by a mound at one corner, crowned with Swiss Pines, and two lesser mounds connected by paved paths. A local Oxfordshire stone was used which, having no natural stratification, presented considerable difficulties in the way of achieving a natural effect in laying it. There were many good plants in the exhibit—*Daphne rupestris*, *Wahlenbergia vincaeflora*, *Silene Veleskyi*, etc., and a cool bog on the north side was well planted with Ferns and *Primulas*.

Miss HOPKINS, Mere, Shepperton, arranged a small group on a curved mound built up with Cheddar stone. It included a number of characteristic plants like the Dresden Daisy, which she has helped to make popular, with good *Sedums* and mossy *Saxifrages*, but the standard *Brooms* seemed out of place, and the moisture-loving *Primulas* were unhappily planted on the crest of a ridge.

The GUILDFORD HARDY PLANT NURSERY, Millmead, Guildford, were a little unfortunate in their use of the raw, unweathered yellowish Bargate stone, and in the too formal disposition of their group as an amphitheatre round a crescent bed in the foreground. *Azalea rosaeiflora* was beautifully shown, and *Sempervivums*, *Oxalis enneaphylla*, *Antennaria dioica*, *Cypripedium*, and *Anthemis* helped to make the group interesting in its plants, but an offending patch of crimson *Mimulus* was planted at the top of a slope.

Messrs. R. WALLACE AND Co., Colchester, essayed a diversified effect in a limited area, with the result that the group had many pleasing pictures in it, and yet lacked cohesion as a whole. On the left were two outcropping bluffs in bold pieces of Cheddar stone, the back one in the shade planted with pale yellows, blues and whites, the nearer one warmed up with a mass of *Phlox Vivid* and sprays of *Saxifraga Aizoon rosea*, with *Campanula Stevensii nana* at a lower level. On the right a little stream dropped down from pinewoods over Fern-clad stones to a small pool in the foreground at the base, giving appropriate sites on its way for *Primulas*, *Cypripedium*, and other moisture-loving plants. Much of the planting was very cleverly done, but one felt that the use of rock garden Conifers was overdone, and that there was a weakness in linking up the whole into one scheme.

Mr. J. WOOD, of Boston Spa, York, using again the weathered mountain Yorkshire limestone which delighted so many visitors last year, built up a rock garden which excelled all others in its restful naturalness and finish. This grey stone is much deeper in tone than the Cheddar, and though it lacks the warmth that the browns and yellows of Lichens give to the long-exposed Somersetshire stone, it has a special beauty in its weathering in deep parallel lines, which connect up easily with neighbouring stones, and whose constant easy repetition gives a feeling of restfulness. Mr. WOOD is an artist, a fact which one appreciated on looking at the little trout beck that tumbled down from the left-hand corner to a deep pool in the foreground. The *Primula farinosa* and *Gentiana verna* in the grass were added touches of perfect taste. The planting scheme was kept low, and though appropriate and beautiful it was felt to be subsidiary, or rather so harmonious with the design that nothing distracting caught the eye. *Sedums*, mossy *Saxifrages*, *Alyssum*, *Erinus*, *Sempervivums*, *Androsaces*—all common things—were used in profusion on the ledges and slopes. But three things seemed out of place: an immense plant of *Azalea rosaeiflora* which made an isolated patch of strong colour on the left, the double *Meconopsis* which almost overtopped the mountain Pines which were just trying to give the effect of distance, and *Veronica salicornoides*, which was used as a plant to line and overhang the water's edge.

Messrs. PULHAM AND SON, Oxford Street, W., made excellent use of a deep plot of ground in creating a miniature rocky glen with bold bluffs:

THE CHELSEA SHOW.

FIG. 163.—PORTION OF MESSRS. J. CARTER AND CO.'S EXHIBIT IN THE LARGE TENT.

valisaiaca, *Campanula Stevensii nana* and other good Alpines.

Messrs. BARRIE AND BROWN, King William Street, E.C., staged a few hardy herbaceous plants and May-flowering Tulips.

Violas in many pretty arrangements were shown by Mr. G. UNDERWOOD, Leicester; Messrs. SEAGRAVE AND Co., Sheffield; Messrs. GUNN, Oltou; Messrs. DOBBIE, Marks Tey; and Mr. H. H. CRANE, Highgate.

Mr. S. MORTIMER, Rowledge, Farnham, exhibited a group of his fine white Stock, named All the Year Round.

Rock Gardens and Formal Gardens.

There were eighteen rock gardens in the open. They stretched along the whole southern boundary of the grounds, Messrs. PIPER'S alone being isolated in a delightful spot near the formal gardens by the main avenue. The exhibits varied in area from over a thousand square feet to less than 300 feet. In character and arrangement the stone used showed a great advance on the exhibits of last year, and the fashionable colour was distinctly grey, several exhibitors utilising the mountain limestone of Yorkshire, with which

it is impossible to have looked at the skilful groupings of stone and careful efforts in planting without feeling that the standard of excellence in rock gardening has been raised to a higher level through the show.

Mr. CLARENCE ELLIOTT, Stevenage, contributed a pleasing piece of work in Cheddar stone, in which a rocky bank was cut through by a path at a low level to give good north and south aspects in a small area. The planting of the encrusted *Saxifrages*, *Ramondias* and *Primulas* was particularly good; but an irregular arrangement of stone on end in the centre of the group rather marred the effect, which large even-sized masses at the base emphasised. *Pentstemon Davidsonii* and *Oxalis enneaphylla rosea* were among the choicest plants.

Messrs. KENT AND BRYDON, Darlington, designed a pleasing little piece of grey Westmorland rockwork. A runnel of water was included at the upper right corner, and was held up by a bog at the bottom. This gave an opportunity for much good planting, and the *Trilliums*, *Gentians*, *Campanulas* and Ferns grouped round it formed a very pleasing picture. *Butterwort*, *Primula farinosa* and *Gentiana verna* in the grass were lively touches of nature that relieved the foreground.

of rock designed in their characteristic style. The stream which traversed the length of the plot was one of the best pieces of water in the rock gardens, but the design was weakened by the unequal planting. Cotton-easters, Lithospermums, and Brooms were well placed, but the large bank of Lilacs and the striking bed of Azaleas in soft shades of pink and cream, however beautiful in themselves, seemed out of place. The German Iris, again, was hardly the right plant for the water's edge. The group, however, was very much admired for its broad conception. It was worked out in the grey Derbyshire limestone.

The show included half a dozen examples of various styles of formal gardening, too different in treatment to allow of easy comparison. They varied from the realistic little Azalea garden of Mr. NOTCUTT, free from stone except in its paving, to the balustraded court and fountain in artificial stone of Messrs. PULHAM. The efforts in this direction greatly exceeded those of any preceding show. It must be remembered that the Society's rules forbade any excavation, and this probably accounts for the raised gardens, which alone would permit of the quiet use of water.

MESSRS. J. CARTER AND CO., Raynes Park, based their design around a central rectangular pool, with spouting dolphins in the centre. On three sides this was surrounded by cross-patterned Horscombe balustrading, clothed with Clematis. The fourth was open to the west, and gave a little low walling for treatment with Alpines. An upper garden was treated with Rhododendrons in rich colours, which bordered the balustrading. The lower was kept quiet with the more restful colours of Darwin Tulips and green turf, and was very pretty. As other examples of the use of Horscombe facing in the garden two styles of garden houses had been erected, the half-open hexagonal one being especially pretty, and near the little lawn was a dove-cote.

MESSRS. R. WALLACE AND CO., Colchester, had the adjoining and similarly shaped plot. It was a garden of quiet colours. At the lower level a border of Irises and Violas, in shades of pale blues and yellows, surrounded a little grass court, overlooked from a well-proportioned garden house. The Roman arches of the house were echoed in the doorway through a Wistaria-covered wall, which led to an upper paved garden. Here three specimen Japanese Wistarias overhung a quiet Lily pool, and Tulips, in shades of mauve and yellow, formed a border bounded by a 3 feet hedge of box. The different levels were opportunities for exhibiting good work in loose walling, and various designs of steps and other work of an architectural character.

Mr. R. C. NOTCUTT, Woodbridge, arranged a very pretty little paved Azalea garden under the shade of the old trees, and governed in its outlines by the existing paths and timber. Standards and dwarfs were used, and the colours cleverly and effectively grouped in the various beds, with Japanese Maples as a foil of foliage. One bed was furnished with R. amoena hybrids and their allies.

MESSRS. J. CHEAL AND SONS, Crawley, showed the uses of their "salignum" arches and temples in a little rectangular garden scheme. The centre piece was a Rose temple, and Rhododendrons, Azaleas, Viburnums, and coloured foliage were allowed to dominate the little formal beds on either side the paths leading up to it. At one end was a paved court, with seats overlooking the whole.

If to be much talked of is a criterion, Messrs. PIPER AND SON, Bayswater, had one of the most effective exhibits of the show in their formal Wistaria garden. It was an attempt to treat an irregularly-shaped piece of ground in an architectural manner, but the object in view was largely defeated by the necessity of maintaining two irregular paths which crossed at the centre and cut the design into four unequal portions. Steps on four sides led up to a central column crowned with Wistaria. Specimen bush Japanese-trained Wistarias stood at intervals on the balustrading, and narrow borders of Lilies and grass plots helped to give some body to a design which was really the "problem picture" of the show.

MESSRS. PULHAM AND SON, Oxford Street, con-

structed a large raised water basin in the centre of a paved court. Balustrade, pergola, fountain, sundial, statuary and other ornaments gave scope for the exhibition of the possibilities of the Pulhamite stone, of which the whole, with the exception of the flag paving, was built. Planting, however, was made subsidiary, and the beds of Lavender and Rosemary were, perhaps, its most important feature.

THE YOKOHAMA NURSERY COMPANY, Kingsway, showed a collection of small Japanese model gardens, dwarfed trained trees in pots, a Japanese tea-house and Shinto temple, and, better than any of these for our Western gardens, some very lovely old pot-grown Wistarias.

MESSRS. LIBERTY AND CO., Regent Street, also showed model Japanese gardens, Wistarias, dwarf Conifers, and various examples of Eastern art in stone lanterns, Bamboo shelters and other garden ornaments.

MESSRS. BARR AND SONS, Taplow, dealing with an awkward, oblong piece of ground, produced an interesting rock garden in the grey limestone from N.W. Yorkshire. At the back it was well and pleasingly planted with such plants as *Gentiana verna*, *Anthyllis montana rubra*, and the Munstead variety of *Cheiranthus mutabilis*. In the foreground, however, we thought the group weakened as a rock garden by the large bed of German Irises, by a large oblong bed, almost exclusively devoted to a rich collection of Orchids with no ground cover, and by using tender *Sarcocodias* on a steep bank above the pool on the left. Iris gracilipes was specially fine.

Mr. MAURICE PRICHARD, Christchurch, Hampshire, also dealt with a rather difficult oblong area of ground, and used the same stone as Messrs. Barr, the grey Yorkshire limestone. The design represented a central moraine, with steep banks on either side, and at the south end; but the planting was hardly in harmony with it. It was really a collection of first-rate plants, each placed in as conspicuous a position as possible, irrespective of its cultural requirements. *Primula pulverulenta* Mrs. Berkeley was especially fine. *Scutellaria indica*, *Cytisus kewensis*, *Androsace primuloides*, *Trollius pumilus*, and *Linaria origanifolia* were a few other things that filled good pockets. Several solid masses of colour provided by *Azalea amoena* seedlings showed how brilliant these little rock shrubs can be; but, at the same time, how dangerous their harsh colours are when let loose among purer shades of the true Alpines.

MESSRS. T. S. WARE, Ltd., Feltham, used the raw Bargate stone. At the best it is difficult to use pleasingly, and in this case was not benefited by the failure to provide any governing plan. It was a collection of good plants—*Astilbe simplicifolia*, *Aquilegia Stuartii*, *Lithospermums*, *Lewisia*, double *Meconopsis*, *Aizoon Saxifragae*, dwarf Phloxes, and many others.

MESSRS. WHITELEGG AND PAGE, Chislehurst, were other workers in the grey mountain limestone. The group was a little flat in its arrangement, and lacked character, except in the very pretty sunless cleft on the left, which formed an ideal site for the cluster of richly-flowered *Ranunculias*. There was a showy central mass of *Edelweiss*, and *Stachys corsica*, *Saxifraga longifolia* var. *latifolia*, and the rose-coloured form of *Saxifraga Aizoon* were well placed.

MESSRS. BAKER'S, LTD., Codsall, Wolverhampton, had good plants rather than a good rock garden. The stone was the white Kentish rag, washed over to bring it into the fashionable grey. The *Primulas* were perhaps the best feature, *P. Veitchii*, *P. sikkimensis*, *P. Lissadell* Hybrid, and others being well represented, but there were plenty of well-grown plants.

Mr. T. H. GAUNT, Farsley, Calverley, built, like so many others, in the Yorkshire stone. At the back it seemed a little overpiled, but this was led up to prettily by drifts of mossy *Saxifragae* and *Veronicas*, and in its deepest face still left good ledges for Alpine plants. There were good clumps of *Dracocephalum nutans* major and *Armeria maritima alba* major.

MESSRS. WATERER, SONS, AND CRISP, LTD., Twyford and Bagshot, had a pretty corner on the extreme east of the gardens, and made good use of it with a steep but well-planted bank, built up of Derbyshire limestone. If it had a fault it was the way in which evenly sized masses were piled stone on stone, each an inch

or two behind the other, and the Conifers used were dotted along at curiously regular intervals. There were, however, plenty of good plants to make a careful examination worth while—*Arenaria juniperina*, *Phlox Douglassii*, *Dianthus arvensis*, *Campanula Allioni*, and *Aethionema saxatilis*.

MESSRS. CHEAL AND SONS, Crawley, confined their rock gardening to planting with rock plants the three outer slopes of a little rectangular formal garden, walled within and topped with Yew. It was a practical suggestion, but not very effective rock gardening.

MESSRS. PIPER AND SON, Bayswater, had a delightfully isolated site near the formal gardens, with a path leading round three sides of it. The foreground was a series of shelves kept so low that 20 feet from the central path the levels had not risen 2 feet. There was much pretty planting here, sheets of *Campanula muralis*, *Saponaria splendissima*, etc., and a lovely little ravine of *Myosotis*, *Pratia* and *Mazus*, shades of blue between whites and purples, especially of *Erinus* (in a flat pocket, where it would almost certainly die of overfeeding!). At the back the stone rose steeply to a crest of Swiss Pines, cut here and there for moraine and drift plants, but both in conception and planting this portion failed to carry on the beauty of the foreground. The general effect was good, but too much of the planting was a colour scheme in carpeting. The work was carried out in Cheddar stone.

AWARDS.

FIRST-CLASS CERTIFICATE.

Adiantum grossum.—This handsome Fern is from tropical South America. It has a vigorous, wiry, black leaf-stalk, clothed with large trapezoid or ear-shaped pinnules of a very leathery texture and bronze-shaded when young. Some of the pinnules are as much as 2 inches in length by 1½ in breadth, and with the black spore-case lining at the under-edge make the Fern a handsome and distinct plant. Shown by Messrs. H. B. MAY AND SONS.

AWARDS OF MERIT.

Pteris flabellata plumosa.—Messrs. MAY found this interesting form in a batch of sporelings from the type. Each little segment of the bipinnate fronds becomes over-developed and lacerated, so that the delicate, almost flat tracery shown by the young fronds becomes with age a richly plumose and dense mass of greenery, reminding one of some of the *Nephrolepis*. Like the type, the variety is an erect-growing plant, reaching 2½-3 feet, and the branchlets come away from the main rachis at the same curiously acute angle. The form is barren, but has been found in some quantity.

Platyterium Cordreji.—A distinct plant, comparable, perhaps, only with *P. Veitchii*, but quite distinct from that species in its broader fronds. It is a stout grower, reaching 2½ feet high, with very leathery, firm, grey leafage, which spreads and branches richly at the tip, erect at first, but arching over at length with its own weight. The barren, branched, light-brown fronds are erect and about 1 foot in height. These two were shown by Messrs. H. B. MAY AND SONS.

Iris Goldenrest.—This variety was selected for award from an interesting collection of seedling Irises to which special reference is made below. It is a pallida × *Cengialtii* seedling, resembling some of those raised by the late Sir Michael Foster, growing about 3 feet in height, flowering early and freely, and having very characteristic unvaried, self-coloured flowers of a bright shade of violet-blue and a good size. The spathes are white and papery. An unbranched spike has sometimes so many as five flowers. The bright yellow beard gives the variety its name. Shown by Mr. W. R. DYKES, Godalming.

Pittosporum Mayi Silver Queen.—The dark-brown stems and grey-green foliage of the type have an added beauty in this variety (to those who love variegation in plants) in the narrow silver edging to each leaf. Shown by the DONARD NURSERY COMPANY.

Calceolaria Stewartii (see fig. 153).—This is a variety of American origin recommended for its qualities as a bedder. It has large, round, flat pouches an inch across, of the richest yellow colour, and borne in the greatest profusion in close, rounded heads. The large (3 by 1½ inches).

rugose, serrate foliage keeps near to the ground, and the freely-branched heads reach a height of about 1 foot. Shown by Messrs. J. VEITCH AND SONS, LTD.

Campanula tomentosa Maud Landale (see fig. 160).—Silvery downy leaves in rosettes at the base and trailing or erect 12-inch spikes of large, pale lavender flowers make this a very pretty plant. The wide cylindrical tube of the corolla is an inch long, and the lobes recurve prettily to show a darker line down the centre of each. Developed spikes carry a dozen flowers. Shown by Miss MAUD LANDALE.

Pinguicula Reutheriana.—A new plant from the Dauphiné. The leaves are oval, about $1\frac{1}{2}$ by $\frac{3}{4}$ inch, disposed flat and with incurved margins as in our British species. The flowers rise on slender 3-inch stems. As shown they were a pale flesh-pink thinly lined with rose and with a violet spur, but in the open flowers are said to be a bright rose-pink. Shown by Mr. G. REUTHE.

Adiantum gloriosum Lemkesii.—This is a garden form, said to have been derived from *A. scutum roseum*. It was shown with *A. Farleyense gloriosum*, and in habit and form it is very close to that variety. Its distinction lies in the pretty salmon-rose shading that suffuses the tender pale green of the young fronds. Shown by Messrs. LEMKES AND SONS, Alphen, Holland.

Oxalis adenophylla.—A pretty species, closely allied to *O. enneaphylla*, but differing in its large rose-coloured flowers and branched stems. The foliage is a pale, silvery green, divided finely into about nine fish-tail segments arranged in a circle. It flowers very freely, each stalk carrying two or three flowers just above the level of the foliage. Shown by Mr. REUTHE and Messrs BEES, LTD.

Begonia Lady Carew.—One of the most beautiful varieties of the tuberous-rooted section, with flowers carmine-rose coloured, a little deeper within, of large size, with perfect centre and unusually smooth, saucer-shaped petals. Shown by Messrs. BLACKMORE AND LANGDON.

Primula secundiflora (see fig. 158).—One of the most beautiful Chinese Primulas in cultivation, having the habit of *P. sikkimensis*, with large, nodding bell flowers of deepest rose-purple, borne in trusses of as many as twenty. After fertilisation has taken place the corolla falls and the pod rises erect to display in a curious fashion the white lines of the calyx. Comparing it again with the well-known *P. sikkimensis*, the leaves, though similar, are smooth, unserrated, and spreading in flat rosettes; the flower stems are shorter and stouter; and the plant as a whole is unfortunately a less satisfactory doer. Shown by Messrs. BEES, LTD.

Clematis Queen Mary.—This is a beautiful variety belonging to the lanuginosa group and, like them, flowering on both old and young wood in summer and autumn. Its value lies in its colour, which is a distinct shade of heliotrope with a sheen of carmine, most marked in bars down the centre. The flowers are about 7 inches in diameter and are more or less intermediate in size, form and colour between its parents, *Ville de Lyon* and *Fairy Queen*. Shown by Messrs. G. JACKMAN AND SONS.

Carnation Scarlet Carola.—A very fine perpetual-flowering variety, with glowing scarlet flowers the size of *Carola*. We noted this variety as a fine novelty at the R.H.S. fortnightly meetings last year, but it has not been exhibited so numerously before. Shown by Mr. C. ENGELMANN.

Lilium regale, shown by Messrs. WALLACE AND Co. This lovely Chinese species received an Award of Merit in 1912 under the name of *L. myriophyllum*, and was now again recommended the same distinction.

Telopea speciosissima (see fig. 152) (The Waratah).—A striking evergreen shrub or tree, with a densely flowered, terminal inflorescence in the shape of a flattened cone, subtended by crimson bracts. The wing-like perianth is blood-red and supports the sessile anthers near the tip; the style is pink, and curves out beyond it, adding to the beauty of the effect. The leathery, evergreen foliage is lanceolate, richly toothed, and new shoots break out just beneath the inflorescence. Shown by the Rev. A. T. BOSCAWEN.

CULTURAL COMMENDATION.

This award was made to the *Telopea*, in recognition of the fact that this was, so far as is known, the first inflorescence to have developed in this country. [This is not the case. A specimen flowered in Sir Geo. MacLeay's garden at Pendell Court in 1882, and was figured in *Gard. Chron.* May 20, 1882, p. 676.—Eds.]

Other Novelties.

Mr. W. R. DYKES, Godalming, sent a very interesting collection of seedling Irises. *Iris chryso-graphes* × *I. Douglasiana*.—This strange hybrid (see fig. 155), between an American and a Chinese species, was perhaps the most remarkable. The seed was sown in 1911, and the plant, now flowering for the first time, bears 11 flower-stems. The form of flower reminds one of *I. sibirica orientalis*. The colour of the falls is a charming pink shade of lilac, a little purplish under the yellow throat patch; the standards also are pale lilac, and are held nearly erect. The stems are solid, wavy in outline, and bear long, leafy, grassy-green bracts which reach up to the flower. *I. Douglasiana* seedlings. — From the typical species, seedlings had given a range of colour from white to violet, an intermediate pale lilac shade being very pretty. *I. Tenax* seedlings. — These also showed an extraordinary range of colour, some self-purple, others pale lilac with darker veins, still others shaded with yellow. *I. Douglasiana Alpha*.—One of the prettiest seedlings: A self-cream colour, lightly veined near the throat with crimson and touched there with golden yellow. A very pretty garden plant, having large spathes shaded with crimson and sometimes holding a second flower. The foliage is grassy, the stems a little straggly. Flowers of *I. Watsoniana* were also shown.

From the Edinburgh Botanic Garden Prof. BAYLEY BALFOUR sent some interesting new Chinese plants recently flowered there. They included *Primula dryadifolia*, a large-flowered gem an inch high; *Saxifraga pentadactylis*, *S. chionophylla*, *S. oranensis*; and a Poppy, probably a form of *Meconopsis rudis*.

Greenhouse Plants.

Messrs. CARTER AND Co., Raynes Park, filled a very large ground space with splendid collections of greenhouse plants. The central mound was composed of *Cineraria stellata* (cactus), of which the quite tiny flowers were a direct contrast to the round blooms of the large-flowered sorts. The outer circles of sweet-smelling Stocks, of *Schizanthuses*, white *Petunias*, *Gloxinias*, *Clarkias* and herbaceous *Calceolarias* linked up the exhibit and made it an exceedingly harmonious whole, which contained especially good strains of the various plants.

Messrs. H. B. MAY AND SONS, Upper Edmon-ton, displayed an attractive group of weeping standard *Wichuraiana* Roses, *Astilbes*, *Hydrangeas*, *Petunias*, bedding *Pelargoniums*, and *Violas*.

Messrs. SUTTON AND SONS, Reading, enclosed their exhibit of greenhouse plants with a series of pillars connected by chains of *Myrsiphyllum asparagoides*, which gave it a secluded and desirable appearance. Inside the boundary several beds surrounded by broad grass walks contained an assortment of splendid plants. In each bed little groups of exceedingly good *Salpiglossis* lightened the more lowly groups of *Schizanthuses*, Stocks, *Primula obconica* hybrids, *stellata* *Cinerarias* and herbaceous *Calceolarias*. All these plants were of exceptional quality, and the tuberous *Begonias* were remarkably fine.

Messrs. STUART LOW AND Co., Bush Hill Park, Enfield, placed in each of the four corners of their group of greenhouse shrubs specimens of *Metrosideros floribunda*, which bore unusually large, crimson inflorescences. *Leptospermum bullatum*, *Ceanothus Veitchii* and *Hydrangeas*, in many varieties, were also included in quantity. The Australian *Boronia polygalifolia*, not so fragrant as *B. megastigma* but of easier culture and of soft pink colour; *Erica Bergiana glauca* and *Azalea rosaeiflora* (a charming little double flower of salmon-pink colour) were also noteworthy.

The exhibit of Messrs. E. WEBB AND SONS, Wordsley, Stourbridge, was in the form of three large mounds, composed respectively of *Cineraria stellata* edged with *Primula obconica* hy-

brids, *Schizanthus compacta* hybrids with *Gloxinias*, and herbaceous *Calceolarias* with *Hippeastrums* and tuberous *Begonias*.

A beautiful exhibit of *Schizanthus* was made by ERNEST G. MOCATTA, Esq., Woburn Place, Addlestone (gr. Mr. Thos. Stevenson). The plants were shapely and literally smothered in blossoms. It is to be regretted that owing to late entry this splendid exhibit was not included in the official list, and consequently received no award.

ALFRED J. WALEY, Esq., Stone House, Reigate, Surrey (gr. Mr. W. A. Dobson), exhibited a group of *Schizanthus* which was composed of exceptionally well-grown plants of a variety of colours.

Mrs. V. A. LITKIE, Clarendon, Maidenhead (gr. Mr. W. Hulbert), also showed a very creditable group of *Schizanthus*.

The collection of *Sarracenias* and allied plants arranged by Mr. A. J. A. BRUCE, Chorlton-cum-Hardy, Manchester, was one of the most distinct and noteworthy exhibits in the large tent. For general elegance and interest nothing could be better, and the design of the group was distinctly good—far better than the average. Low moss-covered arches over a pretty little rivulet spanned by cork bridges made a dainty setting for the many insectivorous plants, and grace and lightness were provided by the slender culms of *Bamboos* and the stems of *Eulalias*. Amongst the *Sarracenias* most prominent were *S. Ashbridgei*, *S. Brucei*, *S. Sanderiana*, *S. rubescens*, *S. Farnhamii*, *S. Drummondii* alba and *S. picturata*, all of which bore fascinating "pitchers."

Messrs. JAMES VEITCH AND SONS, LTD., Chelsea, had *Fuchsias* trained on iron supports to form archways, making a novel and pleasing feature, rising from a table containing splendidly grown *Astilbes* (*Spiraeas*), *Ferns*, *Gentiana verna*, *Aquilegia Stuartii*, *Trillium grandiflorum* and other fine Alpines and border flowers. This firm also exhibited a large batch of *Hippeastrums*, all of magnificent quality, and *Begonia Rex* in variety, in front of a broad row of the yellow *Calceolaria Clibranii*.

Rev. H. BUCKSTON, Sutton Hall, Derby (gr. Mr. Arthur Shambrook), showed magnificent *Calceolarias* of the florists' type, the profusion of blossoms quite hiding the foliage. The group was attractively arranged with *Adiantum Ferns* as an edging.

Messrs. KER AND SONS, Liverpool, showed *Hippeastrums* (*Amaryllis*) and *Anthuriums*. The varieties *Hippeastrum Crimson King*, *Nestor*, chocolate-crimson with white tips; *Alba magna*, white with carmine veins; *Pink Gem*, old-rose colour; and *Fascination*, reddish-apricot with white stripes, were all remarkably good.

Mr. H. N. ELLISON, West Bromwich, showed *Ferns* in variety, and *Cacti* in tiny pots. The latter were exceptionally healthy; these tiny *Cactuses* make admirable subjects for decorative purposes indoors.

Messrs. J. PEED AND SON, West Norwood, showed a large collection of *Streptocarpus* and another of *Gloxinias*. The plants of both kinds were splendidly flowered.

Blue, pink and white-flowered *Hydrangeas* were shown by LEOPOLD SALOMANS, Esq., Dorking (gr. Mr. Geo. Kent). The inflorescences were exceptionally good and evidenced first-class cultivation.

Mr. G. R. SMITH, New Thundersley, Essex, exhibited *Cacti* in variety.

Greenhouse *Calceolarias* were well shown by J. J. WARD, Esq., Rocklands, Finchley (gr. Mr. J. Willis).

Topiary.

Many visitors found much to admire in the large exhibits of topiary, and even those who do not admire the art were compelled to appreciate the great amount of skill and patience which had been expended on the specimens displayed outside the Embankment end of the large tent. The customary forms—birds, beasts and reptiles, barrels, chairs, spirals, and columns fashioned in Yew or Box were shown in large numbers by Messrs. J. PIPER AND SONS, Bayswater; Messrs. WM. CUTBUSH AND SON, Highgate; and Mr. J. KLINKERT, Richmond; whilst Messrs. WILLS AND SEGAR, Onslow Crescent, London, showed standard Bay trees.

Fruit.

Hon. J. WARD, C.V.O., Hungerford (gr. Mr. Chas. Beckett), exhibited 26 fine fruits of Melons, the varieties including Royal Favourite, Superlative, Royal Jubilee, Hero of Lockinge and Scarlet.

Messrs. GEO. BUNYARD AND CO., LTD., Maidstone, showed 50 varieties of Apples and very large fruits of Uvedale's St. Germain Pears, Apples Smart's Prince Arthur, Hambleton Deux Ans, New Bess Pool, George Neilson, Annie Elizabeth, Alfriston and Striped Beehing were surprisingly good for a May show.

In the large tent the KING'S ACRE NURSERY Co., Hereford, exhibited a good collection of pot fruits. In the centre there were many healthy trees of Nectarine Cardinal bearing good crops of nearly ripe fruits. Such Plums as Blue Rock and July Greengage were equally vigorous and fruitful. The front of the exhibit was composed of an unusually good collection of Figs of such varieties as St. John and Negro Largo.

Messrs. LAXTON BROS., Bedford, included a very large quantity of ripe Strawberries in their exhibit. The varieties so well shown were International, Bonntiful, King George and The Earl; all the fruits were of splendid appearance. Standard Red and White Currants, Gooseberries and trained plants of the Loganberry were also shown in good condition. In the open Messrs. LAXTON arranged excellent espalier and grid-iron-shaped and fan-trained trees.

Near the topiary exhibits Messrs. G. BUNYARD AND Co., Maidstone, set up a fruit tree collection, of which the predominant feature was the splendid arches of Pear trees.

Vegetables.

The collection of vegetables shown by the Hon. VICARY GIBBS, Aldenham House, Elstree (gr. Mr. Ed. Beckett), was without its equal in the show. It contained superb dishes of Broccoli Late Queen; Cauliflower Magnum Bonum; Peas Duke of Albany and Early Giant; Vegetable Marrows Custard Table Dainty and The Sutton Asparagus; Potatos May Queen and King Edward VII.; Carrots Favourite, New Red Intermediate and Champion Scarlet Horn; Turnips White Gem and Early Milan; Cucumbers of superb quality, also Radishes, Tomatos, Mushrooms, Beets, Kohl Rabi; Beans, Lettuces, Spinach, Sorrel, Chilian Beet, Globe Artichokes and other kinds.

Messrs. J. CARTER AND Co., Raynes Park, had a magnificent exhibit of vegetables arranged in a very attractive manner on stands of varying heights and ground of black velvet. Peas Early Morn and Eight Weeks; Lettuces Tom Thumb, Brown Dutch and Capucine; Cucumbers Improved Telegraph, Carter's Frame and Ideal; Broccoli Model; Cauliflowers Defiance, Forcing and Forerunner; Turnips Red Top Milan and Long Forcing; Cabbage Springtide; Tomato Perfection; also Radishes, Asparagus, Beets, Beans, Carrots, Marrows and Celery were all shown in superb condition.

Messrs. SUTTON AND SONS, Reading, arranged an exhibit of vegetables on original lines, the group having an imposing background of arches in polished mahogany, some of the dishes being arranged in the recesses on shelves. It was pleasing as much for the style as for the fine quality of the produce. The chief dishes were Broccoli Late Queen, Model and Latest of All; Peas Early Giant, First of All, Green Gem, Duchess of York and Pioneer; Rhubarb The Sutton; Potatos Stirling Castle, Balmoral Castle and others of the "Castle" race; Tomatos Abundance, Dwarf Red and Maincrop; Marrows Green Bush; Cucumbers Satisfaction, Lord Roberts, Unique and Telegraph; also fine Beets, Turnips, Carrots, Beans, and Spinach.

Mr. Bucks, Tresco Nurseries, Ipswich, showed his prolific Tomato, "Buck's Tresco." The fruit trusses were of enormous size, and it is computed that a single truss would develop about 8 lbs. of fruit, and plants 30 to 40 lbs. each.

THE THATCHAM FRUIT AND FLOWER FARM, Newbury, exhibited vegetables in great variety, the various kinds being all excellent produce.

Messrs. H. CANNELL AND SONS, Eynsford, Kent, exhibited a collection of vegetables showing Potatos, Lettuces, French Beans, Tomatos, Cucumbers, Asparagus, Cabbage and other kinds.

Awards made by the Council.

The following is an official list supplied by the Secretary:—

Gold Medals.

Sir Jeremiah Colman, Bart., for Orchids; Charlesworth and Co., Haywards Heath, for Orchids; Sander and Sons, St. Albans, for Orchids; Barr and Sons, Covent Garden, for Tulips; Blackmore and Langdon, Bath, for Begonias; Cutbush and Son, Highgate, for Roses; May and Sons, Edmonton, for Ferns; Sutton and Sons, Reading, for florists' flowers; Veitch and Sons, Chelsea, for stove plants and Azaleas; Webb and Sons, Stourbridge, for flowering plants; Wallace and Co., Colchester, for herbaceous plants, Lilies, etc.; F. Cant and Co., Colchester, for Roses; Dobbie and Co., Edinburgh, for Sweet Peas; Hon. Vicary Gibbs, Aldenham House, Elstree, for vegetables; Sir Everard Hambro, Hayes, for Alpines and Primulas; L. R. Russell, Richmond, for trees and shrubs.

"Daily Graphic" Cup.

J. Wood, Boston Spa, for a rock garden.

The Davidson Cup.

Messrs. Sander and Sons for Cattleya Schröderae var. "Queen Empress."

Silver-Gilt Cups.

C. Engelmann, Saffron Walden, for Carnations; G. Mount and Son, Canterbury, for Roses; W. Paul and Son, Waltham Cross, for Roses; J. Piper and Son, Bayswater, for Wistarias, Hydrangeas, Azaleas, Paeonies, Maples and Tulips; Kent and Brydon, Dartington, for rock garden; R. Wallace and Co., Colchester, for rock garden; J. Wood, Boston Spa, for rock garden; R. Wallace and Co., Colchester, for formal garden; the Duke of Marlborough, Blenheim, for Orchids; Armstrong and Brown, Tunbridge Wells, for Orchids; Cypher and Sons, Cheltenham, for Orchids.

Standard Cup.

W. Cutbush and Son, Highgate, for clipped trees; J. Piper and Son, Bayswater, for formal garden; Manrice Prichard, Christchurch, for rock garden; Allwood Bros., Haywards Heath, for Carnations; A. J. A. Bruce, Chorlton-cum-Hardy, for Sarracenias; R. and G. Cuthbert, Southgate, for Azaleas; A. F. Dutton, Ivry, for Carnations; Fletchier Bros., Chertsey, for Rhododendrons; W. Ierton, Putney, for Lily-of-the-Valley; G. Paul and Son, Cheshunt, for Roses; Phillips and Taylor, Bracknell, for herbaceous plants, Alpines, etc.; T. Rivers and Son, Sawbridgeworth, for pot Citrus, fruits, and vines; Dickson and Son, Newtownards, for Roses and Tulips; Hon. J. Ward, Hungerford, for Melons; James Horlick, Esq. (gardener, W. H. Smith), for Vanda teres and Richardia; J. and A. McBean, Cooksbridge, for Orchid.

Large Silver Cups.

J. Carter and Co., Raynes Park, for florists' flowers; Bunyard and Co., Maidstone, for herbaceous plants and Rhododendrons; G. Jackson and Son, Woking, for Clematis, flowering shrubs, and herbaceous plants; Waterer, Sons, and Crisp, Twyford, for Rhododendrons; B. Cant and Sons, Colchester, for Roses; Veitch and Sons, Chelsea, for greenhouse flowering plants; Mansell and Hatcher, Rawdon, for Orchids; Fromow and Sons, Chiswick, for Japanese Maples; J. Carter and Co., Raynes Park, for formal garden.

Silver Cups.

Cutbush and Son, Highgate, for herbaceous plants; Dobbie and Co., Mark's Tey, for Tulips, Antirrhinums, and Violas; Amos Perry, Enfield, for Paeonies and herbaceous plants; G. Reuthe, Keston, for hardy perennials and shrubs; C. Turner, Slough, for Roses, Azaleas, and Lilies; Backhouse and Son, York, for rock and Alpine plants; Smith and Co., for herbaceous plants; Sutton and Sons, Reading, for Sweet Peas; Sutton and Sons, Reading, for vegetables; Stuart Low and Co., Enfield, for Orchids; Pulham and Son, Oxford Street, for formal garden; Clarence Elliott, Stevenage, for rock garden.

Silver-Gilt Flora Medals.

Artindale and Son, Sheffield, for herbaceous plants; Barr and Sons, Covent Garden, for herbaceous plants; Blackmore and Langdon, Bath, for Delphiniums; J. Rex, Lindfield, for hardy plants; Cartwright and Goodwin, Kidderminster, for Tulips; G. and A. Clark, Dover, for herbaceous plants and Alpines; Cutbush and Sons, Highgate, for Carnations; Cypher and Sons, Cheltenham, for flowering and foliage plants; Dickson and Robinson, Manchester, for Tulips; Gunn and Sons, Olton, for new Phloxes; Hill and Son, Edmonton, for exotic Ferns; Stuart Low and Co., Enfield, for Roses; R. C. Notcutt, Woodbridge, for Rhododendrons, flowering plants, etc.; W. Paul and Son, Waltham Cross, for hardy flowering plants; Peed and Son, West Norwood, for Caladiums; G. Prince, Oxford, for Roses; T. S. Ware, Feltham, for herbaceous plants; Young and Co., Hatherley, for Carnations; Barr and Sons, Covent Garden, for rock garden; T. H. Gantt, Farsley, for rock garden; J. Klinkert, Richmond, for clipped and trained trees; R. C. Notcutt, Woodbridge, for Azalea garden; Donard Nursery Co., Newcastle, Co. Down, for flowering trees; Bide and Sons, Farnworth, for Sweet Peas; Elisha J. Hicks, Twyford, for Roses; E. W. King, Coggeshall, for Sweet Peas; L. Salomons, Esq., Dorking, for Hydrangeas; J. Stevenson, Wimbome, for Sweet Peas; R. Sydenham, Birmingham, for Sweet Peas; T. S. Ware, Feltham, for Begonias.

Silver-Gilt Knightian Medals.

King's Acre Nurseries, Hereford, for fruit trees in pots; Laxton Bros., Bedford, for pot Strawberries and fruit trees.

Silver-Gilt Banksian Medals.

J. Piper and Son, Bayswater, for Topiary and cut trees; Tucker and Sons, Oxford, for rock garden; Waterer, Sons, and Crisp, Twyford, for rock garden; Bees, Ltd., Liverpool, for Alpines; Cutbush and Son, Highgate, for flowering plants; G. Gibson and Co., Bedale, for hardy plants; Harkness and Sons, Bedale, for herbaceous plants; Hobbess, Ltd., Dereham, for Roses; L. R. Russell, Richmond, for foliage plants, Caladiums, Clematis; J. Backhouse, Yorks, for herbaceous plants; R. J. Barnes, Malvern, for Roses; R. H. Bath, Wisbech, for Sweet Peas; C. Bouine, for Tulips; G. and W. H. Burb, Peterborough, for Roses; H. Burnett, Guernsey, for Carnations; Cannell and Sons, Eynsford, for fruit and vegetables; J. Douglas, Great Buckham, for border Carnations; H. Hemsley, Crawley, for Alpines; Vernon T. Hill, Langford, for Alpines; Kelway and Son, Langport, for hardy plants; Ker and Sons, Liverpool, for Amaryllis; Ladhams, Ltd., Shirley, for hardy plants; F. Lilley, Guernsey, for Gladioli and Iris; Stuart Low and Co., Enfield, for Carnations; J. MacWatt, Morelands, for Primulas; G. W. Miller, Wisbech, for herbaceous plants; Paul and Son, Cheshunt, for Lilies; Sutton and Sons, Reading, for Tulips.

Silver Flora Medals.

Amos Perry, Enfield, for Ferns; J. Cheal and Sons, Crawley, for formal garden; Baker's, Ltd., Wolverhampton, for rock garden; Guildford Hardy Plant Nursery, for rock garden; J. Piper and Son, Bayswater, for rock garden; Pulham and Son, Oxford Street, for rock garden; T. S. Ware, Ltd., Feltham, for rock garden; Whitelegg and Page, Chislehurst, for rock garden; R. H. Bath, Wisbech, for Tulips; J. Box, Lindfield, for Sweet Peas; Bertie E. Bell, Guernsey, for Carnations; Cocker and Sons, Aberdeen, for herbaceous plants, Trollius, and Anemones; H. H. Crane, Highgate, for Violas and Violettas; Gunn and Son, Olton, for hardy plants; A. L. Gwillim, Sidcup, for Begonias; Miss Hemms, Tipton-on-Severn, for Sweet Peas; Hogg and Robertson, Dublin, for Tulips; Igham Alpine Nursery, for rock and Alpines; J. Peed and Son, West Norwood, for Glloxinias and Streptocarpus; Reamsbottom and Co., Geashill, for St. Bridget Anemones; Seagrave and Co., Sheffield, for Violas; Thomson and Charman, Adam Street, London, for Alpines; H. Dixon, Wandsworth, for Orchids; Flory and Black, Slough, for Orchids.

Silver Knightian Medals.

G. Bunyard and Co., Maidstone, for fruit trees in pots and Strawberries; Bunyard and Co., Maidstone, for stored Apples; Carter and Co., Raynes Park, for vegetables; Thatcham Fruit and Flower Farm, for vegetables and salads.

Silver Banksian Medals.

Barr and Son, Covent Garden, for Japanese pigmy trees; W. and J. Brown, Peterborough, for Lilies and Gaillardias; Jeffries and Son, Cirencester, for Tulips; H. J. Jones, Lewisham, for Pelargoniums, Fuchsias and Phloxes; Mrs. V. A. Little, Maidenhead, for Schizanthus; C. Waley, Reigate, for Schizanthus; Misses Hopkins, Shepperton, for rock garden; G. Reuthe, Keston, for rock garden; C. E. Waters, Balcombe, for Orchids; Barnes and Brown, King William Street, for herbaceous plants; A. P. Brandt, Blethingley, for Pelargoniums; H. B. Brandt, Nutfield, for Streptocarpus and foliage plants; Rev. H. Buckton, Etwell, for herbaceous Calceolarias; Carter, Page and Co., London Wall, for Dahlias, Violas and annuals; A. H. Cole, Swanley, for herbaceous and flowering plants; Mrs. Lloyd Edwards, Bryn Ogier, for Alpines; H. N. Ellison, West Bromwich, for Ferns and Cacti; J. Forbes, Hawick, for herbaceous plants; Gilbert and Sons, Dyke, for Anemones; W. Lawrenson, Yarm-on-Tees, for hardy Primulas and Alpines; Liss-Jell, Sigs., for hardy Primulas; J. Macdonald, Hupenden, for Grasses; Stuart Maples, Stevenage, for Alpines; R. Prichard, West Moors, for Alpines; Rich and Co., Bath, for hardy plants; G. R. Smith, New Thundersley, for Cacti; G. Underwood, Leicester, for Violas and Pansies; Waterer, Sons, and Crisp, Twyford, for Tulips; J. D. Webster, Chichester, for Sweet Peas; W. Wells, Mersham, for Antirrhinums; Whitelegg and Page, Chislehurst, for Alpines in pots; E. J. Wootton, Eastleigh, for Carnations.

Bronze Flora Medals.

E. C. Bowell, Cheltenham, for Alpines; Burton Hardy Plant Nursery, for Alpines and rock plants; J. J. Ward, Finchley, for Calceolarias; Godfrey and Son, Exmouth, for flowering plants; P. Ladd, Swanley, for flowering plants.

Bronze Banksian Medals.

C. Chantler, St. Mary Cray, for flowering trees, foliage, etc., trees and shrubs; Wils and Sagar, Ouslow Crescent, for Bay trees; Laxton Bros., Bedford, for trained fruit trees.

HORTICULTURAL SUNDRIES.**Standard Cups.**

Jas. Carter and Co., for scientific seed testing, drawings, etc.; Sutton and Sons, for garden tools, cutlery, and other garden requisites.

Silver-Gilt Banksian Medals.

J. Bentley, Ltd., for chemical specialities exhibit; Four Oak Spraying Machine Co., for exhibit of spraying apparatus, etc.; Fowler, Lee and Co., for exhibit of fruit, etc., bottling apparatus, and bottled fruits; The Union of South Africa, for exhibit of South African produce; Walter Voss, for exhibit of insecticides and fertilisers.

Silver Flora Medals.

"Country Life," Ltd., for garden papers; the Elnham Jam Co., for exhibit of jams, preserved fruits,

and lavender water; Headley Bros., for exhibit of garden books and pictures.

Silver Banksian Medals.

Acme Patent Ladder Co., for exhibit of steps, ladders, etc.; Barr and Sons, for exhibit of garden tools; Blake and Mackenzie, for exhibit of flower pots, seed pocket filling machines, etc.; Boundary Chemical Co., for exhibit of weed killer, syringes, etc.; the Dryad Cane and Metal Works, for exhibit of Conservatory furniture; the En-Tout-Cas Co., for exhibit of garden seats, etc.; Hartjen and Co., for exhibit of spraying machines; Hartley and Sugden, for exhibit of sectional boilers, etc.; Vernon T. Hill, for exhibit of slug traps; London Provincial, Etc., Building Co., for exhibit of portable garden house; Mrs. Miller, for exhibit of Moxleyen confections; H. Pattison, for exhibit of horse boots, tools, etc.; J. Pither, for exhibit of mushroom spawn; Pullen-Burry, Ltd., for exhibit of transverse travelling; Robinson Bros., for exhibit of fertilisers, insecticides; Mrs. Sewell, for exhibit of Elmhurst preserves.

Bronze Banksian Medals.

Abbott Bros., for exhibit of Osterley Table Tray, etc.; J. Bradley, for exhibit of the Bunty Tea House; Garden City Trug Co., for exhibit of trugs; Jeyes', for exhibit of insecticides and sprayers; Arthur Key, for exhibition of miniature lawn; C. P. Kinnell, for exhibit of heating apparatus, etc.; C. A. Peters, for exhibit of wood preservatives; J. Pinches, for exhibit of horticultural labels; Prentice Bros., for exhibit of fertilisers; H. C. Slingsby, for exhibit of ladders, barrows; J. Unit, for exhibit of garden tents and chairs; Vipan and Headley, for exhibit of garden seats, arbour, etc.; Mrs. Webb, for exhibit of nesting boxes; H. E. Wemyss, for exhibit of reversible garden chairs; A. Cashmore, for exhibit of garden ornaments.

Standard Cup.

The Yokohama Nursery Co., for exhibit of miniature Japanese Gardens.

PICTURES, STATUARY, ETC.

Silver-Gilt Cup.

Bromsgrove Guild, for pictures and statuary.

Silver Cup.

Howther and Sons, for garden ornaments.

GARDEN PLANS.

Silver Banksian Medal.

A. White.

Bronze Banksian Medals.

Wallace and Co., and Cheal and Sons.

SOCIETIES.

NATIONAL TULIP.

MAY 20 AND 21.—The annual exhibition of the above society was held at the Royal Hospital Gardens, Chelsea, on the second and third days of the R.H.S. Spring Show. The competition and the flowers were much better than of recent years.

Twelve varieties: 2 Feathered and 2 Flamed of each class.—The 1st prize exhibit of Mr. C. W. NEEDHAM, Hale, Cheshire, was so good that all the flowers are worthy of mention. He showed Samuel Barlow (flamed bizarre), Annie McGregor (flamed rose), Ravenshoe (feathered bybloemen), George Hayward (flamed bybloemen), Mrs. Collier (feathered rose), Chancellor (feathered bybloemen), Stockport (feathered bizarre), Sir Joseph Paxton (flamed bizarre), Mabel (flamed rose), Geo. Edward Schofield (feathered rose), Garibaldi (feathered bizarre), and Mrs. Atkin (feathered bizarre). Mr. J. W. BENTLEY, Stakehill, Middleton, who won the 2nd prize, showed good blooms of Annie McGregor, George Edward, Chancellor and Samuel Barlow; 3rd, Mr. A. D. HALL, Merton, Surrey.

Six varieties: 1 Feathered and 1 Flamed of each class.—The flowers in this class were not quite so good as in the former, but Mr. C. W. NEEDHAM's 1st prize exhibit included very good examples of Sir Joseph Paxton and Annie McGregor; 2nd, Mr. A. D. HALL; 3rd, Mr. J. W. BENTLEY.

Three Feathered varieties: 1 of each class.—The 1st prize exhibit of Mr. C. W. NEEDHAM was especially good; he showed Mrs. Collier, Stockport, and John Moodie; 2nd, Mr. J. W. BENTLEY; 3rd, Mr. A. E. CHAFER, Cambridge.

Three Flamed varieties: 1 of each class.—The best bloom in this class was that of Adonis in the 1st prize exhibit of Mr. J. W. BENTLEY; 2nd prize, Mr. C. W. NEEDHAM.

Six Breeder varieties: 2 of each class.—The competition was very good. Mr. J. W. BENTLEY won the 1st prize with splendid blooms of such varieties as Alfred Lloyd, Mrs. Barlow and Lady Grosvenor; 2nd, Mr. A. D. HALL, who had a beautiful Rose seedling; 3rd, Mr. C. W. NEEDHAM.

Three Breeder varieties: 1 of each class.—Although Mr. C. W. NEEDHAM, who won the 1st prize, showed a very fine bloom of Samuel Barlow, the flowers in this class were not of equal merit to the foregoing; 2nd, Mr. J. W. BENTLEY. In the class for six varieties restricted to growers of fewer than 400 blooming bulbs, Mr. A. E. CHAFER won the 1st prize with a collection which included a good bloom of Adonis; 2nd, Mr. Mr. H. S. BARTLEET, Shooter's Hill. Mr. BARTLEET was awarded the 1st prize in the class for three varieties.

The Samuel Barlow prizes were won by Messrs. A. D. HALL and C. W. NEEDHAM in the order named.

SINGLE BLOOMS.

Mr. A. D. HALL won the 1st prizes offered in the classes for single blooms of bybloemen breeder with a good seedling rose breeder with Miss Willmott, and flamed rose with Mabel. Mr. C. W. NEEDHAM was similarly successful in the classes for bizarre breeder with Dr. Hardy, feathered bybloemen with Talisman, feathered bizarre with G. Hayward, and feathered rose with Miss Collier. Mr. J. W. BENTLEY won 1st prizes offered for flamed bybloemen with Talisman, and for flamed bizarre with Alfred Lloyd.

The competition in the Open Class for 20 vases of garden Tulips, 7 blooms of each variety, was much better than last year. Messrs. BARR AND SONS, Covent Garden, won the 1st prize with a beautiful display; 2nd, Messrs. HOGG AND ROBERTSON, Dublin; 3rd, Mr. C. BOURNE, Simpson, Bletchley.

LINNEAN.

MAY 7.—At the meeting held on this date Professor E. B. Poulton, F.R.S., president, in the chair.

Mr. H. N. RIDLEY gave an account of "The Botany of the Utakwa Expedition, Dutch New Guinea," which had been worked up by various botanists. He stated that the extensive collection of plants made by Mr. C. B. Kloss during Mr. Wollaston's expedition to Mount Carstensz, Dutch New Guinea, in 1912-13, is the most important collection of New Guinea plants brought to this country. In spite of the large collections made by Dutch and German collectors, there are upwards of five hundred new species and eight new genera in the collection, many of great interest.

The plants were collected at various heights, from sea-level to an altitude of about 13,000 feet, where vegetation ceased. The areas explored may be divided into four botanical regions:—(1) The Coastal region, where the flora was largely of Malayan affinity. (2) The foothills, ranging from 500 to 3,000 feet elevation, an area of dense forest, the flora still typically Malayan, but containing a distinct Australian element. (3) The Frontal mountain belt, from 3,000 to 8,000 feet elevation, the Begonia and Balsam region. Here cultivation ceased. Palms disappear, and the first of the Palaearctic forms are met with, such as Viola, Ranunculus, Hypericum and Galium. (4) The main mountain range. Here the big forest trees disappear and herbaceous plants show a marked increase.

Casuarinas, Pandani and Violets form a conspicuous part of the flora. The highest tree is Podocarpus papuanus, sp. nov. This attains an altitude of 10,500 feet. Above 11,000 feet the rocks became too steep for most plants, the only plants being Rhododendron bushes, a daisy (Myriactis), some grasses and mosses. The flora of this upper region from 8,000 feet upwards comprised many Palaearctic forms, Geranium, Thalictrum, Astilbe, Euphrasia, Potentilla, Gentiana, etc., with the Australian types Pterostylis and Corysanthes.

Mr. A. F. R. Wollaston exhibited a series of photographs of the scenery and vegetation taken during the expedition, and Major Gage, Dr. A. B. Rendle, Mr. E. G. Baker and Dr. Otto Stapf discussed the paper.

SCHEDULES RECEIVED.

Yorkshire Agricultural Society's Annual Show at Bradford, on Wednesday, Thursday, and Friday, July 22, 23, and 24. Manager of Horticultural Section, Mr. Peter Blair, Trentham Gardens, Stoke-on-Trent.

Richmond Horticultural Society. — Annual Flower Show, Wednesday, June 24, 1914.

MARKETS.

COVENT GARDEN, May 20.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

				Smilax, per bunch of 6 trails	1	0	1	3

REMARKS.—There is a good demand for white flowers, mostly for double white Narcissus and English-grown Stock, which is somewhat scarcer. Double white Narcissus is arriving from Guernsey, but better quality flowers are being received from growers in Lincolnshire. White Pelargonium is selling well. Carnations are more plentiful, and their prices are lower. Malmaisons are arriving in good condition, and trade in these flowers has improved. Darwin Tulips are practically over. Large numbers of Gladioli are arriving from Guernsey, and The Bride variety is in much finer condition. Fine inflorescences of yellow Richardias (Arums) are coming to hand from this quarter, and their prices have fallen; there seems to be no demand for them, and they are only purchased by the chief London florists. Roses are only of a medium quality, but Sweet Peas are arriving in a splendid condition, and they can be had at prices

ranging from 2s. to 12s. per dozen bunches. Iceland Poppies, Paeonies, white and coloured Pyrethrum, Cornflowers, blue-flowered Statice, and white and pink Gypsophila are all being sent in large consignments.

REMARKS.—Business in this department is more brisk, especially among bedding plants. There is a good demand for blue-flowered Hydrangeas, and Ferns also are selling better. Asparagus Sprengeri in pots is selling freely. The scarlet Salvia Pride of Zurich is very popular, also the pink Verbena Miss Willmott.

REMARKS.—Shipments of fruit from Australia and Tasmania to hand this week consisted of 173,000 packages, including Apples, Grapes and Pears. There are large supplies of Strawberries, including baskets, each containing about 4lb. weight of fruit, from French growers. The supply of Peaches and Nectarines from English and Belgian growers is increasing daily. The market is well supplied with both Melons and Figs. English-grown Grapes are available in fairly large quantities. The crops of Cherries and Apricots on the Continent are both very heavy this year. Gooseberries have been a shorter supply this week. Mushrooms are very plentiful, and selling badly, but forced vegetables are scarcer. Asparagus has not been very plentiful during the past week, and supplies of all ordinary vegetables are considerably shorter.—E. H. R., Covent Garden, May 20, 1914.

REMARKS.—Trade in old tubers will soon be finished, but their prices remain fairly firm. New Potatoes also are realising good prices. The supply is quite equal to the demand.—Edward J. Newborn, Covent Garden and St. Pancras, May 20, 1914.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending May 16, is furnished from the Meteorological Office:—

REMARKS ON WIND AND WEATHER.

May 19, 1914.
The centre of a depression of moderate depth travelled eastward across Scotland on Sunday and Monday, and rain, mostly slight, was experienced in nearly all parts of the Kingdom. In various localities in the north-west, north, and east some rain fell on Tuesday also. At some Scottish stations, and also at Rounton, thunder was heard early in the week, and a few places reported snow, sleet, or hail. An anticyclone, which had extended to Ireland from the Azores on Tuesday, subsequently stretched eastward across the United Kingdom, and by the end of the period its central area was situated over the south-west of Norway. This system was accompanied by fair, dry weather, and towards the end of the week, when it came more directly over the Kingdom, the temperature rose from its low figure of the earlier days and became high for the time of year. Until Thursday the main wind current was between west and north-west, and its force light to moderate, but on the following days it was light and variable—mostly easterly in the south, and westerly in the north.

THE WEATHER IN WEST HERTS.

Week ending May 20, 1914.
A Very Hot, Dry, and Sunny Week.—The present term of hot weather came in very suddenly, the previous six days having been as unseasonably cold as the past week has been hot. On the coldest day of the former period the temperature in the thermometer screen never rose higher than 47°, whereas on the warmest day of the past week the highest reading was 75°—a difference of 28°. The difference on one day between the highest and lowest temperature in the thermometer screen was as much as 36°. The ground is at the present time 3° warmer at 2 feet deep, and 4° warmer at 1 foot deep, than is seasonable. No rain has now fallen for eight days, and no rainwater has come through either percolation gauge for six days. The sun shone on an average for nine hours a day, which is three hours a day longer than is usual in the middle of May. On the first day of the week no sunshine at all was recorded, whereas on each of the past four days the sun was shining brightly for between eleven and thirteen hours.

Light airs and calms alone prevailed during the week, the direction of these light airs being mostly some point between north and east. The mean amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by as much as 12 per cent. A selected bush of Hawthorn first came into blossom on the 14th inst., which is eight days earlier than its average date in the previous twenty-three years, and four days earlier than last year.—E. M., Berkhamsted, May 20, 1914.

GARDENING APPOINTMENTS.

Mr. A. H. Campin, for the past 20 years Gardener at The Manor House, Alton, Hampshire, as Gardener to W. H. HERBERT, Esq., Whetstone Pastures, Leicestershire.
Mr. H. W. Jack, of University College, Cork, has been appointed by the Secretary of State for the Colonies, on the recommendation of Kew, an Assistant Agricultural Inspector in the Federated Malay States.
Mr. M. Free, formerly a member of the Gardening Staff of the Royal Botanic Gardens, Kew, has been appointed Gardener of the Brooklyn Botanic Garden, New York.
Mr. H. E. Downer, formerly a member of the Gardening Staff of the Royal Botanic Gardens, Kew, has been appointed, on the recommendation of Kew, Gardener at the Botanic Gardens, Smith College, Northampton, Mass., U.S.A.

LAW NOTE.

TENANTS' CLAIM FOR COMPENSATION.

BEFORE His Honour Judge Mackarness at the Worthing County Court, Mr. G. F. Page, arbitrator under the Agricultural Holdings Act, asked for the Judge's decision, on a point of law, whether the words in a lease, "And any other crops then growing on the said premises," would properly cover bulbs, Paeonies, and Rhubarb. The lease was one which the executors of the late Mr. H. Pullen-Burry and Mr. A. Pullen-Burry held under the Provost and Fellows of Lancing College. That lease terminated last September, and the tenants made a claim under the lease for £9,900, of which £8,180 was in respect of bulbs planted among the fruit trees at Malthouse Farm. When the lease was granted in 1892 it was stipulated that nine-tenths of the farm was to be planted with fruit trees of which there were to be 320 standards to the acre. Terms were arranged of compensation to the tenants for the fruit trees at the end of the lease. Field bulbs were little cultivated, if at all, in England 21 years ago, but it was stated that before the expiration of the lease the tenants had planted some 10 million bulbs on this farm. The claim for compensation for these bulbs was described in Court as twice the value of the freehold of the land. What the County Court Judge was asked to do was to give definite legal construction to those words in the lease, "and any other crops then growing on the said premises." Mr. Barrington Ward (instructed by Messrs. J. E. Dell and Box) appeared as counsel for the tenants; Mr. John Flowers, instructed by Messrs. Freeman and Son, as counsel for the landlords; and the arbitrator was legally represented by Mr. C. J. Sherwood. There was much legal argument over the word "crop." Did crop necessarily mean food? The lease in particular words had mentioned fruit trees; must the words, "any other crops," have some relation to the particular words that had gone before? If so, then as bulbs were clearly not fruit, although the flowers might possibly be described as the fruit of the bulbs, the tenants' claim might not be good in law. But, argued the other side, what does the word "other" mean? Evidently not the "same," more likely something of the opposite. For the landlords it was also argued that the question of movability was important. It was necessary for the arbitrator to find, as a matter of fact, whether the bulbs were movable or not in order that he could put the case properly before the Judge. Landlords did not pay compensation. Mr. Flowers insisted, for things that were in an ordinary sense movable; and there was an affidavit before the arbitrator that the bulbs could be moved without injury between July and September. Another point raised by Mr. Flowers was whether the cultivation of bulbs was detrimental to fruit culture. Mr. Barrington Ward urged that as a matter of fact there were two crops—the crop of blooms and the increase of

the bulbs themselves. This increase of the bulbs was a valuable crop. In the end His Honour decided to take ten days to think over his judgment. What he was going to do, he indicated, was simply to answer the question whether bulbs came within the meaning of the words in the lease.

Judgment was delivered on the 14th inst. His Honour said there could be no doubt that bulbs came under the head of flowers. There were also bulbs producing food plants. The landlords were bound to pay for fruit trees and not merely fruit. They must, therefore, pay for the bulbs and not merely the blooms. His decision was that bulbs, Rhubarb, and Paeonies were included in the words "other crops."

CLAIM FOR COMPENSATION.

At the Redhill County Court on Monday Frederick Humphreys, Norwood Hill, gardener, sued Miss Christabel Ellis, of Little Myntburst Farm, Leigh, for compensation arising from an alleged accident.

The applicant, aged sixty, had an accident thirty-five years ago, suffering injury to the spine, and since then he had been weak in the right leg and arm. For twenty years he was employed by the late Rev. C. J. Lucas, and never had a holiday or an illness. At the end of October he asked Wright, the gardener to the respondent, for a job, which he gave him. His wages were £1 a week. On January 16 he was carrying a plank across a meadow, and stepped into a hole and sprained his knee. He did not see the hole as it was covered over with grass. Witness continued work for a day or two, but owing to the condition of his knee he had to leave his work on January 21. He went to a doctor and received treatment. Up to April 23 he was resting. About a month after the accident respondent's butler called and paid him 10s. for three day's wages, and he (witness) told him the Prudential Insurance Company would not pay him when he applied, as the claim had first to be made to the employer under the Workmen's Compensation Act. His left knee was much better, but not quite so strong as previously. Witness applied to the Prudential Insurance Company for insurance money. The notice was given by the company, and the notice stated that the accident was on January 21.

Dr. C. F. Wakefield, of Norwood Hill, said the applicant had a weak right side, but he could do his work all right. On January 21 applicant came to him, and his left knee joint was hot, painful, and swollen. It was just such a condition that might have been caused under circumstances told by the applicant.

Respondent's counsel submitted that the applicant was a casual workman, and that no notice of the accident was given until March 20, and that the notice was incorrect, so that the respondent was prejudiced.

The respondent said she received the notice on March 20.

His Honour said, in spite of the able argument of applicant's counsel, he had come to the conclusion that the claim must not succeed. It was quite clear that it was the duty of the applicant to satisfy the Court that he had given a written notice to his employer as soon as practicable after the accident was said to have occurred, and if he had not done so he must show that the employer had not been prejudiced owing to his neglect. There was not the slightest doubt that the written notice was not given as soon as practicable. As to whether the employer had been prejudiced, he had lost the opportunity of investigating the facts connected with the alleged accident. There would be judgment for the respondent.

His Honour made an order for costs, on Scale B, against the Prudential Approved Society.

CLAIM FOR COMPENSATION.

At the Clerkenwell County Court, under the Workmen's Compensation Act, an award was made on Friday last, by agreement, of £110 to Mary Dobson, widow, of Aberdeen Road, Highbury, against William Clinton, of Aberdeen Park Nurseries, Highbury Grove, in respect of the loss of her husband.

It was stated that the deceased man, a gardener, met with a fatal accident whilst in the employ of Mr. Clinton at Spencer's Yard, Highbury Grove, on February 10 last.

TRADE NOTE.

MR. H. JENKINS, who for the past six years has been nursery manager for Messrs. Michie and Co., of Alnwick, Northumberland, has been appointed by Messrs. Alfred Spring and Co., Ltd., of London, as their representative for the Midland Counties for the sale of their manure "Stimuland." [Thanks for contribution to R.G.O.F. Box.—Eds.]

ANGULOIA CLIFTONII: B. D. K. *Anguloia Cliftonii* grows best in the shady end of an intermediate house. The plants should be watered freely when growing actively, and partially dried off for a time after growth is completed.

AVOCADO PEAR: C. G. B. We have not seen seedlings of the Avocado Pear (*Persea gratissima*) "growing like Hyacinths in water, and up to 6 feet in height," but as Chestnuts and acorns will germinate and grow to a goodly size when treated similarly it is quite possible that your information is correct, although the height may perhaps be somewhat exaggerated. The seeds of the Avocado Pear should be sown as soon as they are received, and placed in a tropical temperature. A soil similar to that used for *Codiaeums* (*Crotons*) will be found suitable.

FIGS FALLING: C. A. B. There is nothing whatever the matter with your Figs; the only reason for the failure in the first crop is that it appears too early in the year to be fertilised by the agency of insects.

GARDENERS' NOTICE: H. J. In the absence of any agreement to the contrary a head gardener is entitled to a month's notice or a month's wages in lieu of notice, and the mere fact that he is paid weekly for the sake of convenience does not alter his rights. You cannot demand from your present employer any correspondence which he had with your former employer as to your character. If, however, testimonials were given to you personally, and you handed these to your present employer when he engaged you, you can demand them back again.

MELON ROOTS UNHEALTHY: C. I. N. Your Melons are suffering from "Tomato canker." There is no cure for this disease, and the affected plants should be removed and burnt immediately. Careful watch should be kept on plants which now appear to be healthy, and on the least sign of the disease the parts should be cut off and destroyed, or the canker will spread.

NAMES OF PLANTS: W. F. Godwin. 1, *Bougainvillea spectabilis*; 2, We do not recognise the variety; 3, *Arctostaphylos Uva-ursi*; 4, *Eunymus nanus*.—L. B. *Pulkinghorne*. *Berberis Hookeri*.—M. E. *Bathe*. *Cydonia japonica* *Moerloesii* *Salvia officinalis purpurea* variegata. The seedling Broom is near one of the parents of *Cytisus praecox*, namely *C. purgans*.—A. B. C. *Bromus mollis*.—W. B. S. *Chieranthus Allionii*.—L. D. 1, Send in flower or fruit; 2, *Halesia tetraptera*; 3, *Prunus Padus*; 4, *Berberis Darwinii*.—*Hortus*. *Lonicera tatarica*.—W. H., *Bromley*. Both specimens are "The Loquat," *Eriobotrya japonica*.—C. J. E. 1, *Prunus Padus*; 2, *Crataegus punctata*; 3, *Staphylea pinnata*; 4, *Pyrus salicifolia*; 5, *Tsuga canadensis*; 6, *Caragana* sp.?: better specimen desirable.—G. W. 1, *Laelia purpurata*; 2, *Dendrobium chrysothoux*; 3, *Epidendrum cochleatum*; 4, *Maxillaria Harrisoniana pubigera*.—O. T. S. 1, *Dendrobium cretaceum*; 2, *Bulbophyllum auricomum*; 3, *Dendrobium Pierardii*; 4, *Masdevallia caudata*.

NARCISSUS: R. L. F. 1, *N. Poeticus* variety; 2, *N. biflorus*; 3, unrecognised. We cannot advise you how the varieties have been introduced to your garden.

NECTARINES, CRACKING: *Anxious*. The cause of the cracking of your Nectarines is the presence of too much water at the root. The plants absorb more water than the fruits will hold, and the delicate skins burst under the pressure.

NOTICE OF DISMISSAL: J. R. L. In the absence of any agreement to the contrary a head gardener is entitled to a month's notice or a month's wages in lieu of notice. He should give up occupation of the lodge on the same day that his notice expires. In cases of gross misconduct a gardener, like any other servant, can be instantly dismissed, but as you do not mention the reason for dismissal it is not possible to express an opinion as to whether your conduct would have entitled your employer to take such drastic steps. Your son who is working under you would, as a general rule, be entitled to a week's notice. The fact that he was paid fortnightly would not necessarily alter this rule; but it is somewhat unusual to pay wages every fortnight, and this might possibly justify a presumption that a special arrangement of a fortnight's notice was contemplated. Your son could not claim anything for the hire of the bird-cage. No doubt it was understood that the cage would be lent without making any charge, and in the circumstances an agreement to pay for the hire of it would not be presumed.

ONIONS TURNING YELLOW: *Inchicore*. The Onion fly is no doubt the cause of your Onions failing. Syringe the young plants with paraffin twice weekly immediately they show above ground, using a wineglassful of paraffin to 4 gallons of water, keeping the mixture well stirred. Soot used freely is also a good preventive of Onion fly. Plants raised in boxes in a cool house or frame during January and planted out in April seldom suffer from attacks of Onion fly.

RAMBLER ROSES BUDDED LAST SUMMER: A *Reader* *All the Year Round*. As a rule Roses of the *Wichuraiana* section require no pinching back, as they break freely and naturally at the base and become bushy enough. Those of the multiflora group should be cut back to three or four eyes, and this should be done at once.

TOMATO PLANT DISEASED: W. G. Your plant has been killed by the "Sleeping Disease." No cure is known for this pest, but the infected soil must be sterilised by heat before it is again used for Tomatos, or the next year's crop will be affected by the disease.

TREATMENT OF SOIL: *An Amateur*. The advice to bring the subsoil to the top when digging needs qualifying. In such cases as yours, where the subsoil is pure clay, such a procedure, without a considerable amount of after-treatment, would render the garden infertile, for pure clay in its natural state is incapable of supporting vegetation. We are well aware that several successful vegetable growers advocate, and no doubt practice, annual trenching of the kitchen garden soil, but these gardeners are in a position to expend a considerable amount of labour on the soil after the trenching has been done, and to ameliorate it by adding various substances, thus making it very fertile. But the majority of gardeners, who are not placed so fortunately, find bastard trenching to be best, and it is this method that we advise you to follow.

VINE LEAVES: I. F. B., *Elmwood*. There is no *Phylloxera* present in the Vine leaves. The spots are known as "sap-warts"; they are produced by the double condition of an excess of atmospheric moisture and too bright a light. We do not make any charge for replies to enquiries, and have therefore placed the remittance you sent in the collecting box for the Royal Gardeners' Orphan Fund.

THE RED AND BLUE PIGMENTS OF FLOWERS.

THE most beautiful colours in nature—the reds, blues, and purples of flowers and fruits—have withheld the secrets of their composition longest; but, as the result of the work which Professor R. Willstätter (of the Kaiser Wilhelm Institute for Chemistry, Berlin) and his collaborators have carried out during the last three years, the chemistry of these pigments is now known.

So long ago as 1905 incentive to this work was given by H. Moliseh, the distinguished Viennese botanist, who proved that these pigments—which were generally looked upon as amorphous substances—not only exist in many flowers in a crystalline condition, but may be isolated as microscopic crystals.

A paper published last year by Willstätter and Everest foreshadowed interesting developments in this field, but the rapidity with which the investigations have advanced must have surprised even the investigators themselves. Proof has now been obtained that, in all investi-

gated cases, these colouring matters (the anthocyanins) are members of one class of chemical compounds, and, moreover, that they are closely related to the colouring matters of many yellow flowers. This latter result is a confirmation of similar conclusions arrived at independently by various other workers.

To the flower-lover there are many points of interest which arise from this work, and a few such may be mentioned.

It has been shown that most of these pigments—which in themselves are purple—have the power of combining with acids to form substances which vary in colour from bright red to magenta, whereas, on the other hand, by uniting with alkalis, they give rise to blue colouring-matters. The horticulturist who for years has striven to obtain a blue Rose will be interested to know that these researches have shown that the colouring matter present in the red Rose is identical with that which imparts to the Cornflower its fine blue colour. The only difference between them is that in the red Rose the pigment is united with a plant acid, whereas in the Cornflower it is combined with potash. From this it appears that there is no reason why success should not ultimately attend the efforts of those who may devote themselves to the production of this novelty.

In like manner it has been observed that the pigment of the ordinary Poppy does not seem to possess the power of combining with alkalis to produce a blue compound, hence it would appear useless to attempt the production of a blue flower in this case—a variation from red to purple only being obtainable.

For years the deep red Hollyhock has been grown on a large scale in various Continental countries, and the dried flowers have been used extensively for improving the tint of poorly-coloured wines. This adulteration led to many attempts being made to discover a method of detecting the presence of the adulterant, but in view of the very close resemblance between the pigments it seemed almost impossible to expect success, and previously all such attempts had failed. The work of Professor Willstätter, however, has shown exactly how the pigments of the Grape and of the Hollyhock are related to each other, and has led to a successful method—involving the use of ferric chloride—for distinguishing between these pigments.

In most cases the method of obtaining pure crystalline pigments from flowers has been reduced to a few very simple operations, *e.g.*, it is often sufficient to extract the colour with alcohol containing either hydrochloric or acetic acid, precipitate it from this extract by the addition of ether, then take up the solid so obtained in dilute hydrochloric acid, from which it separates in crystals. From the red Rose, crystalline pigment equal to 1 per cent. of the weight of dried petals can thus be obtained, whereas the Cornflower only contains about 0.6 per cent. of pigment, and it is far more difficult to obtain it from this flower. In the *Pelargonium zonale* the amount of pigment rises to 6½-7½ per cent. of the weight of the petals.

It has been shown that the power which these pigments possess of combining with acids is dependent upon oxygen, and not, as is so often the case in organic compounds, upon the presence of nitrogen in them. They contain no nitrogen.

For a long time differences of opinion have arisen as to whether or not these colouring matters—like so many naturally occurring compounds—exist in the plants in chemical combination with sugars. The researches above mentioned prove conclusively that they do.

Thus is added to the credit of the scientist the discovery of one of the most obscure of Nature's secrets, but, like most such work, it leads him on to further problems. His work has shown what these beautiful substances are; the problem now arises, How are they produced in the plant laboratory? Let us hope that ere long this question, too, may be answered *Arthur E. Everest.*

THE BANANA.

TO many people the Banana as put on the table in this country has only one merit—it is easily peeled, and so does not distract the brilliant causeur from his work of setting the table in a roar. But by the travelled man the Banana is always welcomed. Though he may pass it by and take an English fruit, yet he loves to see it, for it recalls memories of hot and hungry tropic-mornings when, after a scrimmage through jungle, he came upon a native village, and ate the delicious fruit ripe and succulent, fresh gathered by his coolies.

Of those pyramids of yellow-golden fingers touched at the base with emerald which adorn the coster's barrows of all our cities, of their origin, cheapness, nutritive value, Mr. Fawcett tells in excellent manner in his book on "The Banana."* From the preface, by Sir Daniel Morris, to the last page of the volume, there is not a dull page, for Mr. Fawcett has put his thirty years' experience of planting in Jamaica into the making of this book.

Incidentally, he destroys some of our illusions: for instance, that which held that the Banana, cultivated as it has been for countless centuries, had lost altogether its power of setting seed. Though this is true of many and perhaps of most varieties, seed has been obtained by fertilising the female flowers of the *Gros Michel* (*Musa sapientum*) with pollen from *Musa Basjoo*, a Japanese species. Moreover, the commonest Philippine Banana, the *Saba*, not infrequently produces seed.

From the recent experiments by d'Angremond in Surinam it is established, moreover, that, whereas the seedless fruits of the Canary (*M. Cavendishii*), Jamaican (*M. sapientum*) and Apple Bananas are produced without pollination, pollen is necessary for the production of seed in the fertile species *M. Basjoo* and *M. ornata*. As is so commonly the case, the best fruits find their way but rarely into the

* *The Banana: Its Cultivation, Distribution, and Commercial Uses.* By W. Fawcett, B.Sc., late Director of Public Gardens and Plantations, Jamaica. Published under the auspices of the West India Committee by Duckworth 7s. 6d. net.

market. The big, coarse fruit of the barrow is a plebeian which triumphs over the smaller, better-flavoured Chinese or Canary Banana, and it owes its triumph to the fact that it can stand the long journey—from Central America or Jamaica—better than the finer fruit of the Canaries.

Another illusion, or error rather, which Mr. Fawcett demolishes is that which imputed synonymy to the Banana and the Plantain. They are distinct. The Plantain is the fruit of *Musa paradisiaca*, and good as a cooked fruit—a tropical substitute for the Potato, and

remains that in most plants pollination gives rise to fruit and seed, and without pollination neither fruit nor seed is produced. It still remains to explain the relatively few aberrant cases in which an unpollinated plant, though it produces no seed, nevertheless produces fruits. The rapidity with which the Banana has established itself on the European market is described vividly by Sir Daniel Morris in his brief but excellent preface. Fifty years ago Jamaica exported fruit to the annual value of £723; to-day the value of its exports of fruit, chiefly Bananas, amounts to 1½ million pounds sterling. In the

ORCHID NOTES AND CLEANINGS.

ORCHIDS AT JARVIS BROOK.

A FEW years ago the firm of Messrs. Stuart Low and Co. purchased a large holding of land on the east side of Crowborough, in the highest part of the Weald of Sussex, a district favourable for the culture of Orchids. The object of acquiring the new land was twofold—to find space for the cultivation of decorative plants and general nursery stock which had become crowded at the main establishment at Bush Hill Park, Enfield, and to remove the large collection of Orchids which had increased rapidly by hybridisation and importation to a locality distant from London and known to be favourable for their culture.

In the open ground are planted large quantities of Roses of all kinds, and large blocks of houses are devoted to the culture of perpetual-flowering Carnations. Our visit, however, was made for the purpose of inspecting the Orchids, which occupy twenty-four spacious houses in two blocks, joined together at the ends by long corridors and heated by seven Robin Hood boilers. The firm specialises in importations of showy Cattleyas, Laelias, Dendrobiums, and other decorative Orchids, and their reputation is well sustained in the collections at the new establishment, for there are thousands of specimens, from the batches imported this spring to the established plants in flower. *Dendrobium Wardianum* is one of the best represented, the large-flowered type often called *Lowii* partly filling several houses, the new importations breaking into from three to nine growths to a plant, ensuring them over the difficulties of the early stage. The extraordinary long-bulbed, free-growing type of *D. formosum giganteum*, which is certainly a new type, with very fine white flowers with yellow centres, gives growers who have experienced difficulties with the old type a fresh chance of success; the dark-flowered *D. nobile*, and a batch of the white form, *D. crepidatum*, *D. dixanthum*, *D. clavatum*, *D. fimbriatum*, *D. crassinode*, *D. crystallinum*, *D. Phalaenopsis*, and other showy species, *D. thyrsoiflorum*, *D. Jamesianum*, and the dwarf floriferous type are all giving bloom. A house of *Renanthera Imschootiana* gives a brilliant display of tall spikes of deep red butterfly-like flowers, and shows it as one of the best plants for the exhibition season. An interesting phenomenon in this house is the presence of a plant of larger growth, but with similar flowers, imported before *R. Imschootiana* was known and probably to be found in the Reichenbach herbarium under another name.

The houses of *Cattleya Mossiae* and *C. Mendelii*, containing thousands of fine specimens, many of them in bloom, are in themselves worthy of a visit. Both species are of the best type, and the variation in the colouring of the flowers is remarkable, the *C. Mossiae*, numerous as they are, scarcely having two exactly alike. A large batch of white and white-petalled forms is present, the forms of the *Reineckiana* section, one of the best of which is *C. M. Magaliae*, and *C. M. Lady Dorington* being specially good. Among remarkable plants in these houses are *C. Mossiae Wageri*, with five flower-sheaths; *C. Mendelii* alba, *C. M. alba* Stuart Low, *C. Warszewiczii* alba Firmin Lambeau, of the F.C.C. and Gold Medal stock; *C. maxima* alba, *C. O'Brieniana* alba, *C. Loddigesii* alba Stanley's variety; and a small batch of white-petalled forms of *C. Percivaliana* and white *C. labiata*. Houses of *C. labiata*, *C. Schröderae*, *C. Harrisoniana*, *Vanda coerulea*, and other standard Orchids, in most of which some fresh arrivals were being acclimatised, were noted; and in many of the houses small lots of rare species imported with the showier things were present.

To mention some of the batches most prominent by their evidence of good culture and free flowering, we found specially good a fine

FIG. 164.—IRIS GOLDCREST: FLOWERS BRIGHT VIOLET-BLUE, BEARD COLOURED GOLDEN.

(See p. 382.)

the Banana is the fruit of one of the almost infinite varieties of other species of *Musa*, the chief of which have been named already.

Those who grow Musas in houses in this country will find in Mr. Fawcett's pages many useful hints, as, for example, the fact well known to travellers that the lower parts of the leaves are so channelled as to conduct rain-water falling upon them towards the base, and the application of the fact that water supplied in this way is important for the proper shooting of the flower-stalk. On one point we find ourselves in disagreement with Mr. Fawcett. He observes (p. 16) that there is no difficulty whatever in understanding how the seedless Banana arrives. To account for the phenomenon continuous selection of poor seeders is invoked. But the fact

economic development of the West Indies Sir Daniel, as is well known, played an important part, and it must be a source of real and legitimate satisfaction to him that the enterprise which he helped to foster has in literal sense borne such a rich harvest of fruit.

As was remarked at the beginning of this account of Mr. Fawcett's excellent work, the book is full of matter, and we may conclude by drawing attention to the account given of attempts to dispense with cold storage in the carriage of this fruit. Experiments appear to show that Bananas may be "shipped" successfully by packing them in peat or other absorbent material, such as well-dried husks of maize. Herein lies a useful hint for those who wish to preserve fruits or seeds of plants generally.

lot of *Miltonia vexillaria* and hybrids densely set with flower; a lot of *Roezlii* and variety *alba*; some fine tufts of *M. Phalaenopsis*, with one pure white form; a house of *Cattleya Trianae* with most of the famous forms; two houses of *Odontoglossums*, chiefly of the best variety of *O. crispum*, in flower or bud, with some excellent blotched forms; one large home-raised variety being of extra merit. Of a number of hybrid *Odontoglossums* some were in flower, and a large lot of *Odontiodas* had fine spikes of brilliant red blooms, chiefly on plants of *O. Vuylstekeae*, *O. Bradshawiae*, *O. Cooksoniae* and *O. Devossiana*.

A small warm house was plentifully furnished with sprays of the white Moth Orchid, *Phalaenopsis Rimstadiana*, with smaller lots of *P. Aphrodite*, *P. Schilleriana*, and a plant of the

leopardinum, and other *Bulbophyllums* and *Cirrhopetalums*, *Dendrobium Victoria Regina*, *Odontoglossum platytilum*, and some very fine scarlet forms of *Sophronitis grandiflora*. Two houses of *Cypripediums* have some plants in bloom, one hybrid between *C. Leeanum* *Clinkaberryanum* and *C. Mrs. Wm. Mostyn* being a fine novelty of perfect shape and rich colouring.

The hybrid Orchids occupy suitable places in many of the houses devoted to the species, and some long ranges are devoted to them entirely. Mr. Jack, who so ably manages this department, showed us batches of *Brasso-Cattleya*, *Laelio-Cattleya* and various other crosses in all stages of development, a very large number being due to flower this and next year. An interesting batch was of *Cattleya Whitei*, both home-raised and imported natural hybrids, the home-raised

For watering purposes rain-water is preferred, but at such an elevation provision has to be made in case of drought, and a pumping apparatus and reservoir have been installed to pump and store the fairly soft water of the district.

THE ROSARY.

SEASONABLE WORK IN THE ROSE GARDEN.

Roses of all kinds are exceptionally early this season. Already at the end of April *Irish Brightness* was in flower, and *Rosa Hugonis* is now in full bloom. This last is a beautiful species, and often a few days earlier than *R. xanthina*, another beautiful yellow-flowered species. It is welcome news that the National Rose Society has officially recognised the name "*Pernetiana*" for the valuable race originated by M. Pernet-Ducher. This group will probably become a very important one. *Madame Edouard Herriot*, one of its best representatives, is fully two weeks earlier than the majority of Hybrid Teas out-of-doors, and if the raisers can give us greater variety of colour in this section, we may expect to have Roses out-of-doors in full bloom by the end of May in favourable seasons. Owing to the heavy rains of March, much of the manure applied earlier in the season has been washed away, and it will be necessary to apply fresh dressings, giving a little at frequent intervals rather than heavy mulchings very seldom. If preferred, the grower can make his own fertiliser instead of buying it. The recipe is as follows:—Two parts dissolved Peruvian guano, one part fine bone-meal, half a part sulphate of potash, one part dried blood, half a part nitrate of soda. All these ingredients should be well mixed together and applied at the rate of 5 ounces to the square yard. The best time to apply it is in the early spring, but even now it would be beneficial, especially in northern districts. Another good mixture is kainit, bone-meal, and blood manure (about 1 cwt. of each) well mixed with three barrowfuls of rather dry potting soil. Leave for two days and then apply a dressing to all the Rose beds; another dressing should be made a month after, and a third after the first blooming. The surface soil should be kept well stirred, and for this reason no small plants should be placed between the Roses. Hybrid Perpetuals should be thinned of all superfluous shoots, especially in the centre of the plant. It is well sometimes to tie out the main growths a little so as to admit the air. Tea Roses on walls will soon be in bloom. They require plenty of liquid nourishment. Rambler Roses, especially *Wichuraiana*, should not be grown too thickly and may be opened out with ropes. Rose pests will be busy this month, and search should be made for the caterpillars of the winter moth and mottled amber moth. Spray with nicotine or tobacco wash, or apply arsenate of lead paste, to destroy caterpillars. The bushes should also be sprayed with potassium sulphide to prevent attacks of fungus. Handpicking is the best method for the eradication of Rose beetles, cockchafers, slug-worms, green Rose maggots, and other grubs. Damaged foliage is often the result of hail or cold winds, but it is sometimes caused by a disease known as black spot. There is no certain cure for this troublesome fungus disease: it is said by Dr. Waddell that the application of formaldehyde will check it. He describes the method of application in the *National Rose Annual* for 1913.

The budding of stocks will now need attention. They should be supported by a small cane or they will soon be blown over. The soil between the stocks and also between the rows should be stirred. If bushy plants are desired for potting in autumn, pinch back the plants at once to about 2 inches. Stocks to be budded

FIG. 165.—*LAELIO-CATTELEYA MEDINA EXCELSIOR*: SEALS WHITE, LIP DARK RUBY-RED WITH YELLOW LINES AT BASE.

(See p. 382.)

rare *P. intermedia* *Portei*. In the next division in bloom were several plants of the elegant blue *Vanda coerulea*, some *Rhyncostylis retusa*, *Coelogyne asperata* (*Lowii*), *C. speciosa*, with good plants of *Vanda Sanderiana*, *Aerides odoratum album*, *Luisia Amesiana*, some fine forms of *Vanda tricolor* and other warm-house Orchids. A house of *Cymbidium*s has a fine lot of the known species including *C. insigne* and hybrids. Some are in flower: one flowering for the first time, *Cymbidium Venus* (*Holfordianum* × *insigne*) has a charming blush-white flower of perfect shape, with small purple spotting on the lip.

Among interesting and rare plants in bloom were the red and purple *Cryptochilus sanguinea*, a small batch of the pretty and fragrant *Ornithocephalus grandiflorus*, *Bulbophyllum*

having the better flowers. *Laelio-Cattleya Dominiana* of very rich colour gave promise for the batch with which it was raised, and *L.-C. St. Gothard*, *Brasso-Cattleya heatonensis* and other *Brasso-Cattleyas*, and the pretty rose and orange-tinted *Brasso-Laelio-Cattleya Fowleri* were in bloom.

In a retired corner of the block is the seed-raising house with its cases of freshly germinated seedlings and store pots of healthy little seedlings, the house itself being filled with plants in their first pots.

In one corner is a sturdy batch of *Sophronitis* crosses, some of which have flowered, *S.-C. Doris*, *S.-C. Thwaitesii*, *S.-C. Blackii*, *S.-C.-L. blechliflora*, and the pretty and interesting *Lowiana insignis* (*Brasso-Laelia Helen* × *Sophronitis grandiflora*).

must be kept hoed. If red rust or orange fungus shows itself the affected parts must be immediately cut off and burnt. Gaps in the beds can

be filled with pot-grown plants, preferably those which were taken from the open ground last autumn. The rest of these autumn-potted plants should be set out in rows about 2 feet apart and 15 inches apart in the rows. Plunge them down to the rim of the pot and keep them moist. They will bloom in July or earlier, and Polyantha Roses especially treated in this manner are very useful for decoration.

FIG. 166.—MILTONIA J. GURNEY FOWLER: FLOWERS CLEAR ROSE-PINK, WITH RUBY-RED MASK.
(See p. 382.)

for a longer period. Climbers such as Fortune's Yellow and Yellow Banksian should be severely pruned after flowering. In the case of the former cut back all side-shoots close to the main

growths. Thin out the main shoots where necessary, and in autumn, when the growth has finished, prune back the growths again. The flowers will then be produced from the basal

eyes and will be especially fine. From Banksian Roses the old wood should be removed, but the fine spray-like growths can be retained. Indoor climbing Roses should be grown somewhat on the lines of a vine, providing plenty of heat and moisture, so that the new wood is produced early. Then in the autumn the houses can be thrown open and the wood well ripened. Experience.

TREES AND SHRUBS.

NEW CHINESE SPECIES.

Concluded from p. 345.

CORYLOPSIS VEITCHIANA is a beautiful spring flowering shrub, with pale yellow flowers, sweetly scented, and containing handsome red anthers. The pendant racemes are about 3 inches long.

EXOCHORDA RACEMOSA VAR. *WILSONII* is a spring-flowering shrub, bearing white blossoms larger than those of the older *E. grandiflora*. It is a strong grower.

GAULTHERIA PYROLOIDES VAR. *CUNEATA* is an attractive little plant, bearing pure white fruits. It is evergreen, and grows to a height of about 12 inches.

GAULTHERIA VEITCHIANA is also evergreen. It bears blue fruits and large leaves.

HYDRANGEA SARGENTIANA is remarkable for its beautiful, velvety foliage, as well as for its handsome blossoms. The leaves, of a dark green colour, are about 10 inches long and 5 inches wide; they are covered thickly with short hairs. The inflorescence consists of a large, flat head containing numerous flowers. The inner flowers appear to be blue, but this is due to the colour of the stamens. Unfortunately, the plant is unable to stand strong sun, and should be grown only in a shady position.

ILEX PERNYI forms a dense, pyramidal bush. The leaves are small and spiny, almost sessile, and set closely on the branches. It is of very slow growth.

ILEX CORALLINA has slender, drooping branches, and is in habit very unlike the majority of Hollies. The leaves are 4 inches to

FIG. 167.—ADIANTUM GROSSUM.
(See p. 382.)

The culture of Roses under glass is a very interesting pursuit, and now is a very good time of year to make preparations for planting out. This method is better than that of pot culture, as the stems of the blooms are much longer. Good, deep soil is necessary, with plenty of bone-meal and well-decayed manure. The best plants to treat will be those grafted this season and obtainable in 48-sized pots. Plant in rows a yard apart and about 2 feet apart in the rows. As they develop cut out every alternate plant; those remaining will soon attain a height of 5 or 6 feet. Melody is a good variety for planting under glass; Richmond makes a fine blaze of colour and Sunburst is extremely attractive. Lady Pirrie would also be most suitable, and so would Cherry Page, which is a lovely shade of pink with a suffusion of golden-yellow. Plenty of heat and moisture is necessary for greenhouse Roses. The flower-buds should be removed in the summer. Hybrid Perpetual pot Roses which have finished blooming should be hardened off, but Teas and Hybrid Teas should be kept indoors until June. A top-dressing of good artificial manure is of considerable benefit to the second growth. Any re-potting which is necessary should be done next month, so that the roots may be well established by the autumn. Rambler Roses in pots which are now showing colour should be watered twice a day on very bright days. They should be placed in a cool situation, as they will thus develop a finer colour. Roses for covering walls and low roofs can be selected from the non-climbing sec-

5 inches long, and about 1 inch wide; they are thin in texture, and bear spines along the edges.

ILEX FARGESII bears long, narrow leaves of a leathery texture, 5 inches to 6 inches

long, and 1 inch to 3 inches wide. They are of a paler green than those of either of the foregoing species. The plant grows slowly and forms a well-shaped shrub.

LONICERA MUPINENSIS forms a bush of about 4 feet in height. The flowers are small, dark red in colour, and are carried on long peduncles.

LONICERA THIBETICA bears long, thin branches and small leaves. It forms a spreading, open bush upwards of 6 feet in height. The flowers are blue, or bluish-purple, and the fruits orange-yellow.

OSTEOMELES SCHWERINAE bears small foliage, and is a neat, compact species. In China it grows to a height of 4 feet.

PIPIANTHUS No. 885 is a much hardier plant than *P. nepalensis* and flowers and fruits freely here in an exposed position. It forms a well-shaped bush.

RIBES LONGERACEMOSUM is remarkable on account of the length of its pendulous racemes of flowers. The blossoms are shaped like an urn and are of a greenish-brown colour, set rather widely apart on the rachis. The raceme, which develops in May, is 18 inches to 20 inches long.

RIBES LAURIFOLIUM is a low-growing, evergreen shrub, with thick, leathery leaves, borne on red petioles. It flowers towards the end of January, and the blossoms (which are of a pale yellow shade) last a long time, and are uninjured by frost. The species is dioecious, and the flowers of the male plant are the more showy. It is a very interesting species, being unlike any other of the genus.

RUBUS LAMBERTIANUS is a strongly-growing Bramble, suitable for growing up poles or pergolas. It is semi-evergreen; part of the foliage falls in the autumn, first assuming a brilliant scarlet hue. The flowers, which are white, are followed by bright yellow fruits.

RUBUS GIRALDIANUS is conspicuous in winter by reason of its gleaming white stems. It grows to a height of 8 feet to 10 feet, and the foliage is very graceful—quite unlike the rather coarse foliage of *R. biflorus*. It should be planted in bold masses, for winter effect.

RUBUS ICHANGENSIS has long, slender stems, which require support. Its chief attraction lies in the curious, steely-blue colour of the leaves. See *Gard. Chron.*, Oct. 25, 1910, fig. 114.

SPIRAEA (SORBARIA) ARBOREA VAR. *GRANDIS* is a beautiful *Spiraea* which flowers in late summer. It is remarkable for the size of its inflorescences, which attain a length of 18 inches and a width of 15 inches across the base. The flowers are white.

SPIRAEA SARGENTIANA flowers in June. It produces in great abundance large, flat corymbs of white blossoms.

STRANSVAESIA DAVIDIANA VAR. *UNDULATA* is an interesting evergreen shrub with a rather variable habit of growth, some plants growing much closer to the ground than others. The leaves are long, of a dark, shining green. The flowers are suggestive of the Hawthorn, and the berries are bright red.

STYRAX WILSONII is a very pretty species. The leaves are small, the stems thin and delicate; the latter bear quantities of white flowers at a very early stage of growth.

VIBURNUM FOETIDUM is evergreen, and has a dense habit of growth. The leaves are light green and thin in texture.

VIBURNUM PROPINQUM is also evergreen, but the foliage is dark and glossy.

VIBURNUM THEIFERUM (6 feet) is deciduous, and bears large, shining leaves. Its chief beauty is said to lie in the large, bright red fruits, but these have not yet appeared on our specimen.

VIBURNUM DAVIDII is an evergreen shrub of low growth and neat habit. The leaves are about 6 inches long. The flowers are white.

CLIMBING PLANTS.

The following section consists of climbers of various kinds, which we have cultivated with success.

VITIS ARMATA VAR. *CYANOCARPA* is an excellent climbing plant, with deep green leaves which assume brilliant colours in autumn.

VITIS HIMALAYANA VAR. *RUBRIFOLIA* is a clinging variety. It bears dark purple leaves with silver-white veinings, and has a very attractive appearance.

ACTINIDIA No. 1029A is a fast-growing species with rough, green leaves. Unfortunately it does not seem to be quite hardy.

ARISTOLOCHIA HETEROPHYLLA is an interesting plant. The leaves are not so large as those of *A. Siphon*, but it bears an abundance of reddish-brown flowers of the same curious shape as those of the last-mentioned species—a shape which gave rise to the name of "Dutchman's Pipe."

ADVANTAGES AND DISADVANTAGES OF LATE WINTER PRUNING.

APRIL has often been recommended as the best time for pruning Apple trees, particularly young ones; but there are disadvantages as well as advantages in this late work. Fruit buds are liable to be knocked off by the pruner, as the least touch brushes them off at that period. On the other hand, the pruner is tempted to leave shoots intact that should be cut, because of fruit buds being at or near the ends. The advantages are, particularly with young trees, that the best wood buds to cut above can be seen late better than early, and, more important, that many buds which looked like wood buds in the winter have

FIG. 168.—*BEGONIA LADY CAREW*: FLOWERS CARMINE-ROSE COLOUR.
(See p. 382.)

CLEMATIS GOURIANA VAR. *FINETII* is an autumn-flowering *Clematis*, which bears large panicles of little white flowers.

CLEMATIS MONTANA VAR. *RUBENS* is a beautiful variety of *C. montana*, and one of the best of spring-flowering climbers. The deep rose-coloured flowers are borne in great profusion, and are slightly larger than those of the type. The foliage and the young stems are rather darker in colour than those of *C. montana*, and by this means the variety can be recognised when not in flower.

CLEMATIS MONTANA VAR. *WILSONII* has much larger flowers than the type, and blooms in late summer.

SINOMENIUM ACUTUM VAR. *CINEREUM* is a pretty climbing plant with shining green leaves and stems. *E. Beckett, Aldenham House Gardens, Herts.*

developed into fruit buds by April, so that pruning can be done by cutting below them where extension is needed. *A Southern Grower.*

SCOTLAND.

GLASGOW'S NEW PARK.—The Glasgow Parks Committee has recommended the Town Council to accept the generous offer of Lord Glenconner to give 15 acres of land on Garngad Road, Glasgow, as a public park, and a sum of £1,000 to meet a portion of the expense of laying it out.

LEITH PUBLIC BOWLING GREENS.—The various public bowling greens in Leith were opened for the season on May 9 by Provost Malcolm Smith. No fewer than 40,000 players used the greens in 1913.

THE BULB GARDEN.

PROSPECTS OF THE LILY SEASON.

THE heavy rains experienced in the beginning of May, and the abundant July-like sunshine which followed so unexpectedly and beneficially in their train, have had a marvellous effect upon the development of Oriental Lilies. This influence has, in south-western Scotland, been especially observable in such fine species as *L. candidum* (which has a deservedly wide circulation in my garden this year), *speciosum*, particularly *magnificum* and *Kraetzeri*, which I account the two grandest

in growth of all my Lilies is *Hansonii*, with its flower-beds distinctly formed, as if its intention were to reveal its golden radiance quite early in June; *Lilium Burbankii*, a vigorous and effective derivative from the famous "Panther Lily" of far California; *L. Henryi*, which, notwithstanding its pendulous habit, has, as Mr. Grove has expressively indicated, high artistic capabilities; and *L. monadelphum* var. *Szovitzianum*, which grows stronger here, and reaches a greater height than I have found it attaining almost anywhere else. By far the grandest grower of all the longiflorums, which are especially adapted for conservatory cultivation,

endured for much longer than two years. I cannot, therefore, recommend them very highly for garden cultivation. *David R. Williamson, Manse of Kirkmalden, Wigtownshire.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

INSECT PESTS IN THE GARDEN AND ORCHARD.
—In reading the articles on the "Market Fruit Garden" by *A Southern Grower*, which are so practical and so frank that they are always full of interest, even to those who do not grow fruit to any extent, one cannot but notice how large a part of the labour and expense in the growing of fruit successfully nowadays is taken up in combating the insect and fungous pests—in the struggle between "the grower and the grub." I think, too, that one can hardly avoid the impression that there must be a flaw in the methods adopted. One paragraph of *A Southern Grower's* recent article (p. 310) is headed "The Forlorn Hope of Spraying." "Fruit-growers," he writes, "keep on spending large amounts of money in spraying without any hope of more than partial benefit." "Spraying against the leaf-curling aphid after an attack has caused the curling is a waste of time and money." "In the case of the apple-sucker . . . it is doubtful whether a single spraying, however well done, kills more than one sucker in ten; at any rate, before the blossom falls." "On examination, two days after the operation (of spraying with a strong soft-soap wash), I find at least half a dozen live pests to one dead enemy." Such expressions of experience could be continued almost indefinitely from other growers and writers. Of course, one would not advocate the abandonment of spraying, but it might be suggested whether more discrimination is not needed. So far as fungous pests are concerned, spraying and washing as at present practised seems to be the most obvious and effective method, and information as to the appropriate fungicides, and the times of their application, is for the most part available. But with regard to spraying for insect pests it seems that perhaps enough consideration has not been paid to the question of the possible destruction at the same time of their natural enemies, and that that may be one reason why the results are so often found to be ineffective and disappointing. To take one insect pest, the most widespread and most protean of all—the aphid. It has many natural enemies, such as the ichneumon fly, and so on. But to consider only one, the lady-bird and its larvae. It seems very likely that indiscriminate spraying might in destroying the aphids also destroy the lady-bird and its larvae, and with the enormous powers of reproduction of the aphid it would matter little whether only one or a thousand were missed by the spraying, if by the destruction of its natural enemies at the same time it was left practically a free field for the rest of the year. As I now grow nothing but Daffodils, Iris and Gladioli I hardly ever even see an aphid, but some years ago, when trying to grow something of everything, including fruit, following a "black Easter" in the spring, my garden was visited with a devastating plague of aphid. I sprayed, but with much the same ineffective results as *A Southern Grower* describes, and gave it up in despair. Later in the year, however, I chanced to observe a colony of lady-bird larvae feeding on the aphid on some badly infested *Lilium candidum*, and I was very greatly impressed with two things—one, the speed with which they cleared off the aphid, and, secondly, that no more aphid reappeared on those plants, as was invariably the case after spraying. Thereupon I went out into the highways and the byways and, provided with a suitable box, I compelled them to come in. I liberated hundreds of lady-birds and their larvae in my garden in this and subsequent years, and though, of course, I can only give it as my impression, I was satisfied that it was at least as effective and more lasting than spraying—and a thousand times cheaper. My experience, however, also seemed to show that even for the aphid only it was unlikely we should be able to dispense with spraying entirely. For the lady-bird

FIG. 169.—PORTION OF ROCK GARDEN EXHIBITED BY MR. WOOD AT THE CHELSEA SHOW.

representatives of this richly fragrant and refined Eastern Lily, *giganteum Szovitzianum*, *Henryi*, *Hansonii* (the extremely graceful "Yellow Martagon"), *Chalcedonicum*, *davuricum*, and *longiflorum Wilsonii*. *Lilium Washingtonianum*, one of the loveliest and most admired of Californian introductions, whose odour is nearly as powerful and pervasive as that of a Magnolia, has also developed with marvellous rapidity; but on the contrary such members of the superbly-endowed auratum family as *platyphyllum*, *Wittei*, and *virginale* have been much more deliberate in their growth, though growing in the finest garden loam enriched with leaf-mould. At present (May 20) by far the most advanced

though they also succeed wonderfully in the open garden (if the soil is fibrous in character, and the situation moderately sunny and sheltered), is the variety called *giganteum*, which must not be confounded by any of my readers with the great Himalayan Lily that proudly bears that name. It has been probably so denominated, not on account of its possessing any gigantic attributes, but because it is more vigorous in its growth and somewhat more commanding in its aspect than other varieties of this exquisite Japanese Lily.

For some years I cultivated *Lilium Kramerii* and *Lilium rubellum*, but I found that though they were precious by reason of their delicate distinctive colouring, they seldom

larvae never appeared, or got to work as early as I could wish, and there was always a period when I awaited its advent with some anxiety. This, to a great extent, might be met by specially breeding them under conditions that would bring them out rather earlier, and it seems that there is an opening for a profitable business in breeding these, and other natural enemies of our insect pest, for distribution to fruit-growers and others. The whole subject of discrimination in spraying for insect pests in relation to their natural enemies is one which, I think, might very well be taken up by the new research committee of the R.H.S., and in due course information might be obtained: (1) Whether in any cases an insecticide could be found which would destroy the pest without injury (or with a minimum of injury) to its enemy; (2) at what times it would be safe (or safest) to spray with this consideration in view; (3) as to the possibilities of breeding the natural enemies of the various insect pests, with a selection of those which would be likely to prove most suitable for this purpose, and how far it would be possible or advisable to replace spraying by these methods. *A. J. Bliss.*

SLUGS IN THE GARDEN.—For years I have been thoroughly disheartened by the damage which has been caused to plants, etc., by slugs. The district in which I live seems to be peculiarly suitable for this garden pest, and I have tried all manner of suggestions for getting rid of them, without success, and the rheumatic idea of going out to gather them up on a damp night I have long since given up. However, I have just discovered a method which has proved a great success. A short time ago I read an article on the slug in a local magazine, and the writer suggested placing pieces of thin board round the garden and examining them next morning. I tried this with the same disheartening disappointment. However, an idea struck me to try scattering a little bran underneath these boards, and on the first morning when I examined them I found about 200 underneath six pieces of board. The slugs seem to have gorged themselves, and the boards being there for shelter they had remained under them. I should be very interested to know if any of your readers could answer the question how the slug discovers from a distance that the bran is underneath these boards. *R. W. Potts, Highfield, Eaglescliffe, Co. Durham.*

THE SOURCE OF YELLOW ROSES.—When my eye caught the heading of the able article of *White Rose* in the *Gardeners' Chronicle* (p. 343) I thought surely now someone has at last discovered how we can produce Roses of the type of Cloth of Gold and Maréchal Niel, and imagine my disappointment at being left as much in the dark as before. Shall we ever know the truth of the origin of Maréchal Niel? Some have asserted that it was derived from Isabella Gray, a Rose introduced by Gray in 1856, and Maréchal Niel was introduced by Pradel in 1864. Of course, this is quite possible. Probably Isabella Gray was obtained from Lamarque, a Rose introduced by Maréchal in 1830, and Cloth of Gold, another derivative from Lamarque, was introduced in 1843. But what I should like to get at is to what species we are indebted for these climbing and dwarf-growing yellow Teas and Noisettes? Can we, I wonder, trace them all to the yellow China Rose (*Thé Jaune*)? I cannot find any date of its introduction, but Wm. Paul says in his *Rose Garden*, p. 303, that "although a fertile seeder it never produces varieties worthy of notice." But supposing it was introduced anterior to Lamarque, may it not through hybridisation by insects have produced some of our yellow Teas and Noisettes? I am afraid the origin of such Roses as Maréchal Niel will now remain a mystery, for I imagine there is no one living who can give us its origin, and certainly old writers are discreetly silent upon the subject. How, then, are we to obtain Roses of the type of Maréchal Niel and Duchesse d'Auerstaedt? Will it not be from the Teas and Noisettes themselves? And will not some of our Continental raisers turn their attention again to their production as their fathers did, instead of continually striving for Hybrid Teas, beautiful and useful though these

Roses are? It is quite evident if we go to the various yellow species mentioned by *White Rose* we shall obtain briar-like nature in our crossings, and can we improve on what Pernet Ducher has done and is doing in this direction? Of course, it is possible for some hybridist to obtain from a blending of these yellow species with some other type as distinct a break as Pernet Ducher obtained with Soleil d'Or, and I would say good luck to his efforts, but what I should prefer to see would be more additions to our Roses of such varieties as Maréchal Niel and Cloth of Gold but lacking their erratic behaviours. *Experience.*

—I do not quite comprehend what *White Rose* means when he says that Rose sulphurea, or hemisphaerica, is always single flowered. Here the flowers are produced in large numbers on elongated sprays of the previous year's wood, and two flowers on one of the peduncles are not at all unusual, whilst sometimes there are three. Parkinson's note shows that he and his contemporaries understood the peculiarities of this beautiful Rose to a remarkable extent. It merely requires the shoots to be severely thinned, the Rose buds less severely, and there is no lack of its glorious blooms. It succeeds equally well here at the foot of a south wall and as a bush partially protected, and I have seen it thriving in one of the coldest districts in the United Kingdom where Hybrid Teas and Climbers are repeatedly cut to the ground, and it unscathed. Probably, therefore, where it fails it is treated too kindly, in the belief, as it was that of Parkinson, that it is less hardy than other Roses. *R. P. Brotherton.*

THE LESSER NARCISSUS FLY.—Since my last note we have now, from an authoritative source, a pronouncement which distinctly assists us to a conclusion, confirmatory, so far as it goes, of the views which I have expressed in this discussion; and destructive, as I venture to suggest, of the theory put forward by Mr. A. J. Bliss, inferentially backed up by Mr. George St. Ox, that this fly acts only as a "scavenger," and therefore is not to be regarded as a pest and enemy of the Narcissus. I quote from the *Journal of the Board of Agriculture*, Vol. XXI., No. 2, just issued:—"The second species, *Eumerus Strigatus*, which may be known as the small Narcissus fly, has only recently proved a serious pest to Narcissus . . . and as it is an exceedingly destructive insect is likely to prove as serious a pest as *Merodon*" (p. 137). This does not look much like only "scavenger" work. And again, p. 140: "The eggs hatch, and the larvae burrow into the necks of the bulbs. Of these larvae some appear to feed rapidly, and are full grown in August. . . . In an advanced stage of the attack the interior of the bulb is entirely destroyed, and is full of a semi-liquid decaying mass." I need not further quote, but I strongly recommend growers of the Narcissus to procure this number of the *Journal of the Board of Agriculture* which deals with the subject in considerable detail, and is admirably illustrated. I may mention that the preventive measures recommended are those which I have already indicated in my notes. *Charles E. Shea.*

IRIS VERNA.—This pretty little Iris, which hails from Virginia and neighbouring States of North America, has just flowered. It appears to have enjoyed the spell of dry, warm weather, and to have done better than is often the case. It is essentially a May flowerer, usually during the third and fourth weeks; but this year it began to open its flowers on the 11th, partaking of the hurry which is so conspicuous this season with our early summer flowers, which have overtaken the legitimate spring flora. *Iris verna*, the spring Iris, is one of the smallest species. It has narrow bright green, tough leaves, 3 or 4 inches long, the flower rises just above on a short, leafy stalk; the long perianth-tube lifting it well above the sheaths. The flower is a brilliant violet-blue, 2 inches in length, rather conical in shape, as the standards are upright and the falls spread downwards. Both are the same colour, but the latter has a broad orange-gold median blotch edged with white, which sets it off extremely well. Thus it catches the eye of man, as no

doubt it is intended to attract the insect visitor. Another point in its favour is the delicious scent of Violets. Parenthetically I may say here that the scent distribution in Irises is very irregular. *Iris Haynei*, which has just flowered, has a strong scent of Lily-of-the-Valley, and is, so far as I know, the only *Oncocyclus Iris* which has a perfume; and among the *Regelias I. Leichtlinii* is very sweet, and *I. Korolkowii* scentless. *Iris verna* is seldom seen in cultivation; it is a slow grower and not an easy one. It needs well-drained soil, not too dry in summer, preferably a loam, rather on the stiff side, but warm. *Elconora Armitage.*

ROADSIDE BEAUTY.—Mr. E. Molyneux's general eulogy of tarred roads is easily confuted by my own particular experience. In his view the tar is "a boon to plants, especially fruit-growers. . . ." I own two cottages by the side of the main road here; one is not at all beautiful, so I screened it with pillars of *Wichuriana* Roses. The other is occupied by my gardener, who has trained similar Roses up the side of the cottage. An outlying part of my own gardens comes down to the road, from which it is bounded by a low wall covered with Roses. In every case the Roses have been killed or crippled by the tarring of the road. Two fine Plum trees, planted as a screen to the road, have been badly injured. There is no doubt about this at all; the fine particles of tar at the time of its application were carried by the wind and covered the wood and the foliage. I could quote other instances in this neighbourhood. *G. H. Engleheart, Little Clarendon, Dinton, Salisbury.*

THE R.H.S. AUTUMN FRUIT SHOW.—The new regulation (No. II.) issued by the Royal Horticultural Society for competitors at the Autumn Fruit Show in September next has come as a great surprise to a large class of exhibitors who have hitherto shown as "amateurs" or "private gardeners" in Divisions 1, 4, 5, and 6 at this annual show, and it seems likely that such a drastic alteration of the former regulation must seriously, and perhaps injuriously, affect the whole character of the exhibition, as well as the actual exhibitors and their gardeners. Of course, the Council of the R.H.S. is within its rights in classifying so-called "amateurs" as "market-growers" if they grow fruit for sale even in the smallest area, and although the fruit so grown may not be of the kind suitable for exhibition at this autumn show such growers can have no real ground for complaint, and must bow their heads to the alteration; but what about their gardeners? Their case appears to me a hard one where they have only their gardens to look after and grow fruit for show, while the fruit orchards for market purposes are under the independent charge of a bailiff or head farm man. Such cases must be fairly numerous in the fruit-growing districts. These gardeners, many of them distinguished and most capable men, will now lose the small and well-deserved extra emolument arising from the winning of money prizes; their employers will cease to show, and there will be no further need in many gardens for the skilful cultivation of the best sorts, both old and new, of Pears and Apples, and the nurserymen will suffer seriously in consequence. Surely it would be a pity to thus endanger the stability of this important annual show in this sudden, and, in my opinion, ill-considered way. If we are all, both small and great, to be classified as "market growers" cannot something be agreed upon in the shape of a sliding scale, and the prizes formerly allotted to the amateur divisions be readjusted accordingly? This should certainly be possible if approved of and taken in hand by the Fruit Committee, and I would suggest a classification of all market growers according to the acreage of fruit grown by them, commencing, say, at 10 acres up to a total area of 250 acres and over. This would, I think, increase instead of diminish the interest in the show, and would at any rate stimulate the smaller growers and their gardeners to continue their present useful work. The prizes might at the same time be judiciously restricted to the very best well-flavoured Pears and Apples to the exclusion of the large showy and in many cases tasteless varieties now unfortunately so much in favour for exhibition purposes. *Savile G. Reid.*

The Week's Work.

THE ORCHID HOUSE

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

THE CATTLEYA HOUSE.—Many of the plants that flowered early in the year in this house are developing their new growth, whilst those that flowered late last summer and autumn are also well advanced. Afford the plants every encouragement to grow freely in plenty of sunlight, but take care that the sun's rays do not cause scorching. Plants in flower include *Cattleya Mendelii*, *C. Mossiae*, *Laelia purpurata* and the numerous primary and secondary hybrids from these. Afford the roots plenty of moisture whilst the flowers are expanded, but as soon as the spikes have been removed reduce the amount to just sufficient to keep the pseudo-bulbs plump until such time as the new breaks have grown well beyond the base of the old stems. Many of the plants need to be repotted during the next few weeks, but not such as are producing their flowers, unless the flower-buds are cut off. It is better to defer the work of repotting until the flowers are removed or until new growth commences. Shade carefully all newly-potted plants until the roots are re-established, and afford very little water to the soil, for the growth is best kept moist by spraying or sprinkling through a fine rose on the water-can. If sprayed once or twice a day in favourable weather, and the stages are kept moist, there will be no danger of the plants shrivelling. To keep insect pests in check spray with an insecticide regularly once a week during the next few weeks.

PERISTERIA ELATA.—Plants that are not developing their flower-spikes are starting into growth, and the work of repotting should be done as soon as growth commences, as roots develop rapidly, contemporary with the new top-growth. It is not desirable to repot the plants annually; once in two years should suffice. For that reason compost of a lasting nature should be used; it may consist of one-half fibrous loam, the remainder of peat, leaf-mould, sand and broken crocks or charcoal. See that the pots are clean and filled to about one-third their depth with material for drainage. When the plants have been turned out of the old compost back pseudo-bulbs that are not of service may be removed and repotted to increase the stock. Make the compost firm, and shade the plants carefully from strong sunlight for a few weeks afterwards.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

THE FORMAL GARDEN.—Just now is the busiest time of the whole year in the flower garden, for the beds have to be cleared of the spring-flowering plants, made ready, and replanted with their summer occupants. It is now safe to make a start with the summer bedding, but it is always wise to reserve the more tender subjects, such as *Begonias* of various types, *Heliotropiums*, *Dahlias*, *Ageratums*, *Coleus*, *Cannas* and *Celosias*, for planting last. If standard plants of such subjects as *Plumbago capensis*, *Streptosolen Jamesonii*, *Lantanas* and *Fuchsias* are used as "dot" plants, it is essential to have them well hardened by exposing them to the night air before they are set in the beds. Such plants cannot easily be afforded protection when in the beds, but, should the weather turn cold, it is easy to protect dwarf bedding plants by sticking short branches of Yew, Box, Laurel or other evergreens in the ground about them. These sprays of evergreen have not only the advantage of protecting the plants from high winds and low temperatures, but they also shade them, and thus keep the atmosphere about them humid, which is a great advantage before the roots are re-established. If the plants can be kept from flagging by this means there

will be no need to resort to frequent waterings, which not only may cause the soil to become cold and sour, but also entail a great expenditure of labour.

COLOUR SCHEMES.—One of the most pleasing examples of bedding that I noted last year was a pair of medium-sized beds arranged with two shades of the same colour. The ground was composed of *Ageratum Malvern Beauty*, of a beautiful lavender-grey colour, and at intervals were arranged standard plants of the strong-growing *Ageratum mexicanum* of a deeper tone. The effect, and especially at twilight, was enchanting. Another arrangement that pleased me consisted of *Viola Bullion*, as a ground to standards of *Calceolaria amplexicaulis*. A further design had a groundwork of *Heliotropium Lord Roberts*, with standard plants of the darker variety *President Garfield*.

HERBACEOUS BORDER.—Hardy perennials are growing rapidly, and attention must be paid to such details as watering the roots and staking the shoots; it is a good plan to stick a stout branching stake, such as is used for the support of Sweet Peas, in the middle of a clump and allow the plants to grow through the loose branches, which will afford them support in a more natural manner than when tied to an ordinary stake. Arrange the sticks so that they lean outwards, for if growth is directed inwards the interior of the plant will be crowded and the appearance will be too rigid.

MICHAELMAS DAISIES.—The remarks on staking apply especially to perennial *Asters*, and these plants should be well thinned; in the case of large-leaved and strong-growing kinds, 1 foot apart is not too much space for the individual shoots.

ANNUALS.—These plants are growing rapidly, and if evergreen branches had been placed amongst them for protection they may be removed. *Nemesias*, *Verbenas*, *Salpiglossis*, *Scabious* and certain other kinds should be stopped with a view to securing plenty of side-shoots for flowering. Most annuals are shallow-rooting plants, therefore in dry weather do not neglect to water them freely. A little soot scattered over the soil before watering will benefit the plants, causing the foliage to assume a deep green colour. Sprinkle a little artificial manure on the soil occasionally and place twiggy sticks to support the growth, allowing the plants to grow naturally through the sticks.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY,
Knowsley Hall, Lancashire.

LILIAM.—Liliums on which flower buds are forming should be removed from the pits to an intermediate house, and the shoots secured to stakes. Give the roots copious waterings of liquid manure and weak soot-water. Guard against green fly, which attack the points of the shoots. Later batches of *L. auratum*, *L. speciosum album* and *L. s. rubrum*, also *L. s. Melpomene* are developing roots on the stems close to the bulb; top-dress the plants with equal parts of good loam and decayed manure, but allow space for watering. Gradually inure the plants to more air and a lower temperature, and where local weather conditions permit, stand them out-of-doors on a bed of coal ashes in partial shade. Afford water very carefully, for an excess may cause the soil to become sour. When roots appear on the surface and flower buds show, feed the plants twice weekly until the blooms develop, removing to an intermediate house when the flowers begin to show colour. Stake each shoot securely.

RICHARDIA AFRICANA.—These plants are showing signs of maturity, and should be placed out-of-doors in a position where they may receive full sunshine to complete their ripening. Withhold water from the roots gradually until early in August when the plants may be overhauled and repotted. This applies to such as are grown all the year round in pots. Plants showing signs of deterioration will benefit if hardened off and planted out early next month in a well-prepared, richly-manured trench. Remove all

suckers from the main root-stock, and place the latter 15 inches apart.

BEGONIA.—Continue to pot rooted cuttings of fibrous-rooted *Begonias*, using a light porous compost. Tuberos-rooted *Begonias* grown from seed in January require larger receptacles; enrich the compost with a little pulverised cow manure, and pick off the early flowers to throw all the strength into the plants for the present. Afford weak liquid manure to established plants showing flower, and support the shoots to neat stakes. Frequent light fumigations will keep mite in check.

CHRYSANTHEMUMS.—The composition and preparation of the compost for the final potting of *Chrysanthemums* are details of importance. The loam mellow from storage should be broken up into pieces, and mixed with mortar rubble, sand, leaf-mould, and bone-meal. Mix the materials well, and after a week turn the heap again. Use clean pots, and let them be well drained, placing moss or some of the coarser portions of the compost on the crocks. Before the final potting securely stake the plants, and harden them to enable them to be placed outside. To check rust, add a wineglass of petroleum to four gallons of warm water, and syringe the plants once a week with this specific, which should be kept in a state of agitation, so as to mix the oil with the water. To destroy aphid dust the foliage with tobacco powder.

FRUITS UNDER GLASS.

By W. HEOLEY WARREN, Gardener to the Aston-Clinton
Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buck-
inghamshire.

THE VINERY.—Attend to the vines in the succession houses, as formerly directed, and thin the bunches and berries in later vineries. Bunches that are required to hang on the vine during the greater part of the winter should be thinned more freely than those that are intended to be cut when ripe. Special attention should be given to vines planted in March or April, and every encouragement given so that they make a rapid, healthy growth, and in this way cover the allotted space with good, strong foliage. Young vines growing freely in a well-prepared border are benefited by copious waterings and a warm, moist atmosphere. When the leading growth has attained to a length of 8 or 10 feet it should be stopped, thus concentrating the energy of the vine in the main rod, that it may become properly matured. This will also allow the foliage to develop more freely, and the tendency of the leaves to fall will be eliminated in a way that is not so apparent when the main and side-growths are allowed too great a freedom. Muscat varieties that are swelling their berries require plenty of heat and moisture: it is therefore necessary to damp the paths, staging, etc., during the early morning and again several times during the day when the weather is bright and sunny. The house should be closed in the early part of the afternoon, and the night temperature not allowed to fall below 70°. If exposed to the direct rays of the sun Muscat Grapes are somewhat liable to scald, especially those on the upper side of the bunches; therefore, if necessary, during the hottest part of the day in very hot weather lightly shade that side of the house on which the sun is shining. Probably a light temporary shading will suffice, as it is only necessary to break the fiercest rays of the sun, at the same time allowing of the admission of sufficient light. The roots of Muscat vines should be generously nourished, and at least every three weeks suitable quantities of food should be applied to the roots. If the vines are extra vigorous and carry a heavy crop of fruit, and the borders are well drained, it may be necessary to feed them even more frequently. The borders of a Muscat vinery must never be excessively wet nor sodden, for this would be fatal to good results. Vigorous vines may be allowed to carry a reasonable quantity of lateral growths, which will do no harm, but rather assist in maintaining an equal balance between root and foliage and ensure a healthy state of root activity. Early varieties, such as Black Hamburg, require a temperature

not lower than 60°, and artificial heat must be employed. Let the air circulate freely both day and night, for when the atmosphere is in constant motion moisture does not condense on the berries. The soil in the borders does not require to be as moist as it was when the vines were in full growth, but it should not be allowed to become so dry that the surface cracks. It is an easy matter to keep the border in a correct state of moisture with but little watering if a suitable mulch of dry litter or leaves is employed.

MELONS.—The plants, if healthy and clean, should not be destroyed when the early fruit is cut. If the bad leaves are removed, the growth regulated, and the plants well watered with liquid manure made tepid, a fresh crop of fruit equal in all respects to the first will soon develop. If, however, the plants have become infested with red spider, thrips, etc., any attempt at successive cropping would be useless, and the plants should be uprooted and destroyed. Pollinate the flowers of plants in pits and frames daily, and place the fruits that have set on pieces of slate, tile or glass, to prevent rotting. A bottom heat of 70° will suffice at this time of the year, and the atmospheric temperature should range from 70° to 80°. Guard against infestations of red spider by damping the surface of the bed frequently, admitting plenty of air, and close the lights early in the afternoons.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

ENDIVE.—A small sowing of this vegetable for cropping early in autumn should be made now or very soon. It is important to transplant Endive when the seedlings are very small, and the plants will do well in almost any kind of soil. Usually a finely-divided variety is chosen for earliest use, and Broad Batavian for subsequent sowings.

POTATOS.—The haulm is growing very strong this year, and no delay should occur in preparing the ground for the final earthing-up of mid-season and late varieties. Satisfactory crops can be produced without drawing soil to the stems, but, except in ground of a very light nature, unless earthing-up is practised some of the tubers are sure to become green through exposure, and where the growth is vigorous the haulm is apt to be partially prostrated, both of which are obviated by proper earthing.

TOMATOS. It is safe to plant Tomatos that have been properly hardened in the open in districts where they succeed. Even in the north Tomatos will furnish fair crops provided the plants are well advanced at time of planting, and not more than two or three clusters of fruit left, the tips being pinched beyond the third truss. But the fruit is always deficient in flavour, and much of it fails to colour till picked and matured under glass. Very serviceable fruits may be grown by affording the plants the protection of ordinary cold frames, the plants in this instance being planted close to the fronts and trained near to the glass, and very slightly ventilated. In glass structures growth must be regulated carefully and frequently to prevent crowding, nor should side-growths be left to grow beyond an inch or so. Should the white fly make an appearance vaporise the plants with nicotine at once, and again at brief intervals till all the insects are destroyed. Plants bearing heavy crops must be fed with stimulants, either dissolved in water or sprinkled among the plants and washed in the soil.

BROCCOLI AND OTHER BRASSICAS.—It is the practice of some growers to prick the seedlings into beds to gain strength before finally putting them into their permanent positions. I find they succeed equally well transplanted direct from the seed bed, and at this period most of the plants are large enough to handle. The roots are drawn through a solution of soil and water, planted deeply in drills, watered, and afterwards left to themselves. Firm ground is very important for this crop, so that growth may be slow and hard enough to endure the cold of winter. This is one reason why the plants should have a long season. Nor does early planting affect the time of cutting. At

present we are using late varieties which were planted a year ago. Later than this Broccoli is not wanted, because Cauliflower is ready to cut from plants set in the autumn.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

GOOSEBERRIES.—The crop is very early this year, and a large proportion of the fruit may be picked when green for preserving, and for uses in tarts, etc. If choice Gooseberries are required for dessert, the fruits should be well thinned, leaving only the best berries to ripen. A mulch of decayed manure will assist the bushes and ensure clean, healthy growth. If extra fine fruit is desired, afford the roots copious waterings during hot, dry weather, and feed them with liquid manure and concentrated fertiliser alternately; when the fruit is ripening use only clear water. Nets will be required to protect the fruit from the birds, unless the bushes are grown in a wire enclosure. Guard against caterpillars, red spider, and other insect pests; red spider is often a source of trouble to Gooseberries, especially those growing in very light, hot soils, and the bushes will soon become unhealthy if prompt measures are not taken to destroy the pest.

CORDON AND STANDARD GOOSEBERRIES.—The fruit on cordon-trained Gooseberries can be picked easily, and at the same time the trees produce very fine fruit. To ensure a succession of berries early and late varieties must be planted. Attend to the pinching of the shoots, so that plenty of light and air can reach the fruit. Pinch back the side growths to four or five leaves, and these will form fruiting spurs for next season. Should they start to grow again, remove the secondary shoots. Tie the top shoot to the support early, extending it to its full length. Cut away all shoots as they appear at the base of the tree. Standard Gooseberries are an attractive novelty, and help to break up the uniform appearance of the kitchen garden. Take care to support the heads by the use of strong stakes.

PEACHES.—Our trees have set a good crop. Attend to the preliminary thinning of the fruit, leaving the final thinning until later. Remove all badly-placed and twin fruits, and a moderate number of the others, according to the crop and state of the tree.

THE "FRENCH" GARDEN.

By PAUL AQUATIUS.

CLOCHE BEES.—The Cos Lettuces have been cleared from the beds and the cloches removed. The Carrots growing as an intercrop should soon be ready for pulling. Let the Carrots be well watered, also the crops growing in unheated beds, so that they may be marketed from late in June to the end of July. Make arrangements for successional cropping for the autumn. The main crops are Cauliflowers, Celery and Carrots for the manure beds; late Celery, Endive or Beans for the cold ground. Cos Lettuces, Cabbage Lettuces, Endive, Radishes, or Spinach may be grown as intercrops; the selection may be regulated in accordance with the local demand.

MELONS AND CUCUMBERS.—Most of the Melon beds are completed. The beds for Marrows may be made immediately and the soil covered with a row of cloches, which will shelter the young Melon plants till frames and lights are at liberty during the next fortnight. The weather has been very favourable to this crop, and full ventilation should be afforded from 8 a.m. till 5 p.m., except for those planted last, which need to be shaded carefully for a time. Stopping of the main stems while the plants were in the nursery beds has resulted in two laterals developing, which should be stopped at the fourth or fifth leaf, care being taken to have 3 or 4 inches of clear stem from the collar of the plants. As the side shoots develop stop them after the second leaf; this will cause other shoots to form, and these are stopped after the first leaf. These shoots will bear female flowers in great numbers and always produce the best fruits. Though the plants are kept moist at the roots, watering should not be excessive to obtain a hard and

sturdy growth, but after the fruits are set water may be afforded liberally. Cucumbers are planted in similar beds as for Melons. The plants are set 1 foot from the front of the frame, slanting the stem towards the top. Keep the lights closed and shaded, with mats preferably. Though moisture-loving plants, Cucumbers grown in frames find plenty of moisture in the damp ground, and the grower should regulate the watering according to the growth of the plants and the state of the weather.

OUTSIDE CROPS.—The Cabbage Lettuces are being marketed daily, and these will be followed closely by the Cos varieties (autumn sown). They are best pulled early in the morning and placed in the shade of a shed until the evening, when they should be dipped once in clear water and packed in hampers. As soon as the ground is cleared of the crop hoe and rake the surface in preparation for the Cauliflowers, which are set as an intercrop. If the plants are heavily mulched it will save much labour in watering and the produce will be of better quality. Carrots and Turnips sown in March and April need copious waterings, for the roots are forming and should be ready for marketing from the third week in June. The crops of Onion, Cabbage and Spinach set in the autumn have been marketed; the ground is available for growing Kidney Beans, Witloof Chicory Turnips, Cauliflowers and Red Celery. Once the space is prepared for either of these crops no plant or seed should be inserted till the ground is thoroughly soaked either by heavy waterings or rains. The planting of the Tomatos is completed and the plants will be benefited by the shelter of cloches until the middle of June. Kidney Beans should be set from the seed-bed in rows at 18 inches apart. A succession can be obtained by inserting seeds direct into the ground, taking care not to plant them deeply. A second sowing of Witloof Chicory should be made before the second week in June to produce roots for forcing after Christmas in succession to those sown in May. If cloches are available ridge Cucumbers may be set in the open ground and covered with the cloches until well established.

MANURE BEES.—The crops of Carrots and Turnips have been marketed and the beds should be hoed and well raked. The Cauliflowers will soon occupy the whole space, especially if they are watered freely. The plants should be examined daily with a view to covering with the leaves such inflorescences as are exposed to the light. Some of the heads should be ready for cutting within a few days; the crop should be disposed of at the earliest opportunity, as they are valuable in the first fortnight in June.

THE APIARY.

By CHLORIS.

WATER.—I have often strongly recommended the supply of water during dry weather in the breeding season. Some weeks ago I came across an excellent idea. The drinking water had a little salt added (about a teaspoonful to a pint); this was done to prevent bees getting their saline water from a contaminated source, such as drains from a manure heap. Then the water was placed under a shelter, made by placing four bricks on end and putting a piece of board on top just larger than the water vessel. The idea had occurred to my friend because the faeces of bees have been reported by the Board of Agriculture experts to be a fruitful source of spreading the infection. All apiarists ought to be aware of the fact that bees drop their faeces whilst on the wing, hence the point of covering over the water supply. There is only one further suggestion I would add in carrying out the idea; wash out the drinking vessel several times during the week with disinfectant.

SUPERS.—In fruit districts the supers should be put on, even if it be necessary to crowd the bees on seven or eight frames by using the divider. To secure good work the supers should be very warmly wrapped up and packed so that no heat may escape or draught enter, as this is fatal. An old beekeeper once said, what will keep the heat in will keep it out, and so for this purpose use plenty of non-conducting material.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.
 Editors and Publisher. — Our correspondents would oblige by delaying in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPOINTMENTS FOR JUNE.

TUESDAY, JUNE 2—
 Scottish Hort. Assoc. meet
 WEDNESDAY, JUNE 3—
 Roy. Hort. Soc. Coms. meet. (Lecture at 3 p.m. on "Iris.") B.G.A. Ex. Council meet.
 THURSDAY, JUNE 4—
 Nat. Hardy Plant Soc. Sh. at R.H.S. Hall, Westminster. Linnean Soc. meet
 FRIDAY, JUNE 5—
 Dundee Hort. Assoc. meet. Soc. Française d'Hort. de Londres meet.
 MONDAY, JUNE 8—
 United Hort. Ben. and Prov. Soc. Com. meet.
 WEDNESDAY, JUNE 10—
 Birmingham Bot. and Hort. Soc. Orchid Sh. (provisional).
 SATURDAY, JUNE 13—
 Stirling Hort. Assoc. outing to Greenfield, Alloa. R.H.S. Gardens Club outing.
 TUESDAY, JUNE 16—
 Roy. Hort. Soc. Coms. meet. and Nat. Gladiolus Soc. combined show. (Masters Memorial Lecture by Prof J. Bretland Farmer, F.R.S., D.Sc., at 3 p.m.)
 WEDNESDAY, JUNE 17—
 Yorkshire Gala (3 days).
 THURSDAY, JUNE 18—
 Linnean Soc. meet.
 WEDNESDAY, JUNE 24—
 Richmond Fl. Sh. Croydon Hort. Soc. Fl. Sh.
 THURSDAY, JUNE 25—
 Isle of Wight Rose Soc. Sh. at Ryde (provisional). Roy. Botanic Soc. meet. Sherbourne Floral Fête. Canterbury, Kent Rose Show.
 SATURDAY, JUNE 27—
 Windsor, Eton and District Rose and Hort. Soc. Sh.
 TUESDAY, JUNE 30—
 Roy. Hort. Soc. Summer Sh. Holland House, Kensington (3 days). Roy. Agricultural Soc. Ex. at Shrewsbury (4 days).

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 57.2°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, May 27 (6 p.m.) Max. 59°. Min. 40°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, May 28 (10 a.m.): Bar. 29.7; Temp. 64°. Weather—Bright Sunshine.

PROVINCES, Wednesday, May 27; Max. 55°, Seilly; Min. 47°, Aberdeen.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Hardy Bulbs and Roots, at 1. Palms and other decorative plants, at 5. At 67 and 68, Oheapside, E.C., by Protheroe and Morris.

FRIDAY—

Orchids. At Protheroe and Morris's rooms, at 12.45.

A valuable contribution to the subject of the influence of radio-active substances on plant growths has been made by M. Georges Truffaut, the results of whose experiments are published in *Jardinage* (May, 1914).

M. Truffaut's record of his investigations is prefaced by an interesting account of the progress of knowledge with respect to radio-activity and radio-active substances.

Knowledge on this subject dates from 1896, in which year Becquerel discovered

that uranium salts, although themselves non-luminous, give off emanations which pass through sheets of black paper and act on photographic plates enclosed therein.

The investigations of Professor and Madame Curie on radium led to the introduction of the term radio-activity to express the facts which they discovered concerning the emanations which are given off by radium. These emanations have remarkable properties, and produce remarkable effects. They pass through metals such as aluminium, but are arrested by sheets of the heavier metals—lead, for example. They cause diamonds and rubies to fluoresce, and they induce obscure but profound changes in living tissues.

The discovery that a radio-active substance such as radium renders the air or other medium in which it is contained a better conductor of electricity, provides an electrical method whereby the existence of radio-active substances may be discovered, and as a result of the application of this method it is now possible to obtain from various minerals supplies of radio-active substances. By this means compounds of thorium, polonium, and actinium have been isolated, and their radio-activities investigated. Moreover, it has been found possible to compare the radio-activities of these various substances, the unit (U) of comparison being the radio-activity of a gram of black oxide of uranium.

Measured by this standard, the radio-activity of radium is two million units and that of mesoradiothorium four million.

As an indication of the enormous amount of energy liberated in the emanations from radium it may be mentioned that one gram (about 15 grains troy) of radium liberates in the course of its disintegration some three million million heat units—i.e., about as many units of heat as are liberated during the combustion of over 1,000 lbs. of coal.

Beside affecting the electric conductivity of the air, the emanations from radium and similar bodies possess potent chemical properties. They decompose water into its elements, and thus setting free oxygen bring about oxidation processes.

That radio-activity affects the growth of plants was demonstrated by Stoklasa, who showed some years ago that seedlings treated with water containing radio-active substances develop more rapidly than normal seedlings.

Later experiments in France showed also that radio-activity produces an effect on vegetation, and that on a soil of low fertility and poor in nitrogen the effect is but slight. These experiments also indicated the most serviceable quantity of radio-active substance to use for horticultural purposes.

M. Truffaut's first series of experiments was based on these facts, and involved the use of radium bromide as the radio-active manure. The experiments were carried out with Haricot noir de Belgique, Tropaeolums, Sweet Peas (in pots), Anthemis, and Chrysanthemums.

The soil used was rich in nitrogen and in mineral substances. The results of the

experiments were remarkable. They showed that the radio-active substance had exerted a marked influence on growth, but that this influence, instead of resulting in an increased yield, brought about a decreased yield.

This fact, though at first sight disconcerting, is by no means fatal to the prospects of radio-active manures. For M. Truffaut observed that the crops treated all showed conspicuous evidence of having enjoyed a surfeit of nitrogenous food, and those which had the largest doses of radio-active manure were found to suffer most from this excess of nitrogen.

That this conclusion is correct seems possible from the fact that in the case of the Haricot noir the later crops taken from the treated plants were somewhat larger than those from the untreated plants; indicating perhaps that as the stores of nitrogenous food material in the soil became less copious the radio-active substances produced a beneficial effect. Somewhat similar results were obtained with Anthemis, except that with them the best plants were those which received $\frac{1}{2}$ per cent. manure containing $7\frac{1}{2}$ per cent. of radio-active substance. More manure or more radio-active substance produced a less good result.

In a second series of experiments carried out by M. Truffaut and Dr. Szilard the relative values of different radio-active substances were investigated.

The materials employed were:—

- (1) Insoluble radio-active compounds—viz., oxides of uranium.
- (2) Insoluble minerals of low radio-activity.
- (3) Soluble compounds of low radio-activity.
- (4) Strongly radio-active compounds.
- (5) Radio-active residues from the commercial extraction of radium and mesothorium.

The experiments were carried on with Chrysanthemums in pots, and each pot received so much of one or other radio-active manure that the number of units was the same in all the pots. The soil used was well supplied with nitrogen, but less rich than that used in the preceding experiments: $\frac{1}{2}$ per cent. of a complete fertiliser was added to the potting soil.

In the early stage of the experiment symptoms of excessive nitrogenous feeding, similar to those exhibited by the Haricot noir, were observed. But by August, when the plants were flowering, those treated with certain radio-active substances were manifestly superior to those which received manure only.

Of the treated plants the best were those which received $\frac{1}{2}$ per cent. manure (i.e., 1 part manure to 100 of soil) together with an amount of carnotite equal to $7\frac{1}{2}$ per cent. of the manure.

That is to say, the proportions were:—Soil, 20,000; complete fertiliser, 100; radio-active substance (carnotite), $7\frac{1}{2}$.

Each pot received about $\frac{1}{3}$ gram (5 grains) of carnotite, which is a mineral of low radio-activity. Next in order of excellence were the plants which received 5 per cent. instead of $7\frac{1}{2}$ per cent. of carnotite. Those to which black oxide of uranium

KALMIA LATIFOLIA (NAT. ORD. ERICACEAE)

(From a photograph taken in the R.H.S. Gardens, Wisley, Surrey.)

was added (11 milligrams per pot) were also good, but less so than the foregoing. M. Truffaut concludes from these experiments that (1) radio-active substances produce a definite effect on vegetation; (2) the insoluble radio-active substances give at least as good results as those given by soluble radio-active substances; (3) radio-active minerals or oxides give the best results; (4) the use of black oxide of uranium is practicable; for the results are good and the price low. This substance costs about £1 per pound, and one pound suffices for about a ton of soil; (5) it may be dangerous to use radio-active residues of commercial manufactures, since these residues may contain poisonous substances — e.g., salts of barium, sulphuric acid.

In conclusion, it is to be observed that experiments carried out by M. Truffaut with Spinach in the open gave no well marked results.

Our Supplementary Illustration.—

Kalmia latifolia is a native of the mountainous districts of North America, and may be ranked amongst the most beautiful of the hardy evergreen shrubs. It belongs to the Ericaceae, and thrives best in a moist, peaty soil, although it will grow in a sandy soil that does not contain lime. The fine specimen illustrated in the Supplement is growing in the gardens of the Royal Horticultural Society at Wisley, and measures slightly over 5 feet high by about 7 feet broad. The flower buds are just commencing to open, and are somewhat in advance of those on plants of the same species growing in other parts of the garden. This is probably due to the shelter which is provided on the north by a Holly hedge and on the east by large Rhododendrons. Our photograph was obtained in July last.

Coloured Supplement for next week.—

The subject of the Coloured Plate to be published with our next issue is *Philesia buxifolia*.

NEW SUPERINTENDENT OF PUBLIC PARKS AT SHREWSBURY.—Mr. ARTHUR WARD, who has held the office of foreman in the Birmingham City Parks for the past six years, has been appointed Park Superintendent of the borough of Shrewsbury. Mr. WARD, who is a son of Mr. JAMES WARD, Superintendent of Public Parks at Norwich, gained experience under his father in the Norwich parks for some years, and has also been employed in the Royal Gardens, Windsor, Welbeck Abbey Gardens, Warren House, Stanmore, and elsewhere. His fellow employees at Birmingham have made him a presentation as a souvenir on the occasion of his taking up his new post.

NATIONAL ROSE SOCIETY.—PRIZES OFFERED IN AMATEUR CLASSES.—A correspondent writes as follows upon the new regulations of the National Rose Society:—"A new feature of the N.R.S. schedule of prizes for the summer show to be held at the Botanic Gardens, Regent's Park, is that each of the 1st prizes to be awarded to amateurs consists of a piece of plate instead of the money prizes heretofore offered in the majority of the classes, save that where challenge cups have been offered in former years these, with their money prizes, some three or four in all, are still maintained. As this leaves nearly seventy classes for which these pieces of plate are to be provided, it will clearly give a good deal of work to those deputed to select the prizes, and it will also be an interesting question whether the alteration will be

appreciated, and the exertions of the selection committee appreciated. Exhibiting Roses is an amusement by no means free from expense, and there can be little doubt that in the past many exhibitors, especially those who come from a distance, have been in the habit of looking to the prizes they may secure either to recoup themselves some of this expenditure, or to furnish new Roses for the next season's campaign. Clearly the seventy pieces of plate will be of little service in this respect, and more than one intending exhibitor has already been heard to say he would prefer to secure the second rather than the premier position. Possibly the Society may have been thinking less of the convenience of its members than of carrying into effect something of the nature of a self-denying ordinance to accompany the increased stringency in its definition of an amateur which takes effect this year. Or again, it may be regarded as a form of economy. In the case of the notable classes, such as the Amateur Champion class or the Metropolitan Champion class, the offer of a cup or permanent trophy of some kind is reasonable enough, but they are scarcely likely to be thought of equal value when multiplied to the extent indicated above. Pieces of plate distributed in this quantity may even become rather a burden than an acquisition. However, it is only by experiment that progress is effected, and perhaps by its new departure the Society may be enabled to ascertain in what direction a move may best be made. Exhibitors as a class are not wont to be reticent in expressing their views, and it scarcely admits of doubt that they will cause their opinions to be known before the summer is over."

FLOWERS IN SEASON.—We have received from Mrs. INA SCOTT-ELLIOT, of Teviot Lodge, Hawick, a number of fine, long-spurred Aquilegias. For the past fifty years Mrs. SCOTT-ELLIOT has been at work improving the strain of these attractive flowers, and has produced some extremely fine varieties. Among those she has now sent us, those with red flowers are especially noteworthy; the collection also includes mauve and pink flowers of very delicate tones. From Messrs. KELWAY AND SON, of Langport, Somerset, comes a box of Pyrethrums, showing the latest developments in this flower obtained by this well-known firm. Wilson Barrett is a fine double flower of a bright rose-pink colour. General Buller is a single flower, of which the petals are deep, flaming crimson, lighter on the reverse, while the centre is bright orange-yellow. Mary Anderson is an attractive double variety, the outer petals being a pretty shade of rose-pink, and the inner ones tipped with yellow. Queen Alexandra is a white double flower.

AGE OF HEATHS.—From the *Pharmaceutical Journal* we learn that the monks of the Great St. Bernard Hospice have gathered, for purposes of micro-examination, several specimens of Ericaceous plants growing at altitudes from 2,000 to 2,400 metres. As a result, the following ages have been attributed by F. KAMGESSER, the well-known scientist, to the plants he examined:—*Vaccinium vitis-idaea*, thirteen years; *Vaccinium myrtillus*, two years; *Calluna vulgaris*, thirty-three years; *Rhododendron ferruginosum*, one hundred and three years.

APPOINTMENT.—The County Council of North Wales has appointed Mr. WM. WILLIAMS, of Hengrave Hall, Bury St. Edmunds, as Horticultural Instructor, University College, Bangor, North Wales.

THE WORLD'S CORN CROPS.—The Board of Agriculture and Fisheries has received the following telegram from the International Agricultural Institute:—"A condition premising an average yield being represented by 100, the condition of crops in certain countries on May 1 was as follows:—Wheat: Spain, 110; Roumania, 115. Winter Wheat: United States,

112. Rye: Spain, 110; Denmark, 106; Netherlands, 105; Roumania, 115. Barley: Spain and Roumania, 110; Japan, 106. Oats: Spain and Roumania, 110. The condition of cereals in Belgium, Russia and Sweden was good, and in Italy and Algeria, average.

MATTHIOLA INCANA.—Herr SPRENGER describes (*Osterr. Garten Zeitung*, Heft 5, 1914) the variations exhibited by *Matthiola incana* in the wild state. On the rock cliffs at Gaeta it bears pure white flowers. In the vicinity of Naples it is dark blue. On the coast of the peninsula of Sorrento Herr SPRENGER has seen it blue and white striped. In Majori its flowers are red, in Liguria blue or violet, in Silesia sometimes violet and sometimes red, as it is also on the inhospitable coasts of Corfu. Whether the white form in Gaeta is a true wildling or whether it be an escape from cultivation is hard to say. If the latter, Herr SPRENGER says that we should expect to find the double form as well; but this is scarcely so, since, as is now well known, only some individual singles carry the power of producing doubles. In the Mediterranean the wild Stock is a shrubby plant with woody stem. It lives for five or six years, branches vigorously, and may reach a yard in height. The smooth leaved *M. incana glabra graeca* is, however, dwarfier.

A NEW WINTER-FLOWERING BEGONIA.—

A promising addition to the numbers of winter-flowering Begonias is *Melior*, a plant described by Messrs. J. A. PETERSON AND SONS, of Cincinnati (U.S.A.), in *Möllers Deutsche Gärtner Zeitung* (No. 13, 1914). The plant is the result of a cross between Lonsdale's Light Pink (a sport from *Begonia Gloire de Lorraine*) and *B. socotrana*. The hybrid is a strong grower, from 1 to 2 feet high, with dark-green, roundish leaves. It flowers profusely and its male flowers, which are from 1½ to 2 inches across, possess each four petals. The female flowers, which are formed rarely, have five petals. In colour *Melior* is of a delicate rose, somewhat lighter than *Glory of Cincinnati*. Flowers are produced from November to March, and are at their best in December and January. During flowering-time the plant should be kept at a temperature of about 58°. Propagation is easy, and cuttings root well in a mixture of equal parts of turfy loam and leaf-mould, to which some sand is added.

CITROPSIS, A NEW GENUS ALLIED TO CITRUS.—The Citrus-like plants of equatorial Africa, hitherto classed in the genus *Limonia*, have been investigated recently by W. T. SWINGLE and MAUDE KELLERMAN, of the U.S. Bureau of Plant Industry (see *Journal of Agricultural Research*, Vol. 1., No. 5, 1914). The plants in question have fruits of from 2 to 3 centimetres in diameter, in groups of 2 to 5 borne on the axils of the leaves. ENGLER has grouped these African species of *Limonia* in a new section, *Citropsis*, thus distinguishing them from the true *Limonias* of the Asiatic mainland. The authors above cited conclude, however, that these plants must be separated from *Limonia* and placed in a new genus *Citropsis*. The relation of the African plants is said to be closer to *Citrus* than to *Limonia*, and in this conclusion the authors are confirmed by the fact that the plants may be budded easily on commonly cultivated species of *Citrus*.

THE WILD SNAPDRAGON.—An article by Herr SPRENGER on "The Snapdragon at Home" (*Osterr. Garten Zeitung*, 4, 1914), describes the variation exhibited by this plant in the wild state. As in gardens, so in nature, the *Antirrhinum* shows great variety. In Corfu its flowers are violet-purple with yellow lip; but white-flowered forms are not uncommon. On the walls of the King's palace at Rome the flowers are of a delicate lilac-rose tint; but Herr SPRENGER has not seen a wildling with pure yellow flowers. The wild plants, though they blossom sparingly, have flowers which are not

smaller, but if anything larger, than those of the cultivated plant. A wild, small-leaved form exists. The Snapdragon which is common in Corfu is in Greece confined to the islands Hydra, Tenos and Naplia.

SPRING FORAY IN THE FOREST OF DEAN.—The sixth informal spring foray of the British Mycological Society will be held in the Forest of Dean from Friday, May 29, to Tuesday, June 2. Daily forays will be made from the Saturday to the Tuesday inclusive, and the various places to be visited will be selected on the previous evening. The hon. secretary and treasurer is Mr. CARLETON REA, 34, Foregate Street, Worcester.

A RUST-PROOF STOCK FOR ROSES.—M. LOUIS WEIGAND, writing in the *Handelsblatt für den Deutschen Gartenbau*, claims that he has obtained a stock, which he names Weigand Rust-free Canina, that is completely resistant to rust. It arose among the firm's stock of *R. canina*, and is said to have other valuable qualities—e.g., freedom from spines, wood which is hard, not brittle and with little pith, hardy with well-developed, compact root system. All the varieties which have been budded on it develop vigorously.

ROSES AND DAHLIAS.—We learn from the *Board of Trade Journal* that H.M. Consul-General at New York (Sir C. W. BENNETT, C.I.E.) reports an enquiry from New Jersey for the names of the leading English and Irish growers of Roses and Dahlias for export. The name and address of the enquirer may be obtained by United Kingdom growers of Roses and Dahlias for export on application to the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall Street, London, E.C. Any further communications regarding the enquiry should be addressed to the British Consulate-General, New York.

GRAPES FROM ARGENTINA.—According to the *Board of Trade Journal*, H.M. Legation at Buenos Aires reports that the first trial shipment of Grapes from Argentina to the United Kingdom left Buenos Aires on April 17. The fruit, which is stated to be of first-class quality, comes from the vine-growing district of the Province of Mendoza, and the consignment consists of 1,336 boxes of about 7 kilogs. each (a kilog. equals 2.204 lbs.), and 290 boxes of about 3½ to 4 kilogs. each. The fruit is packed in skeleton boxes and is laid within wooden shavings. Should this trial shipment prove a success there is a possibility of a large trade in Grapes between the Argentine Republic and the United Kingdom.

THE HEMP PLANT AND ITS PRODUCTS.—The Hemp plant (*Cannabis sativa*), though sometimes grown as a garden plant, is pre-eminent for its economic uses. In cool countries the durable fibre contained in its stems is employed in the manufacture of rope, etc. In hot countries it is grown for the narcotic resin deposited on the leaves, flowers and fruits of the growing plants. In India three distinct products are thus produced, namely, Ganja, which consists of the tops of the female inflorescences that are covered with the resin, Charas, which is the resinous substance itself, and Bhang, the mature leaves. They are all used for smoking; but Bhang is also used as an infusion in the preparation of an intoxicating drink. Ganja is known as a drug in this country, and comes into English commerce under that name, or as "hashish," and is usually in compressed dark-green masses. In English medicine it is employed either in the form of a tincture or extract. Little is known about these products, except by those who trade in them; but some interest was recently aroused by a report in the daily Press of proceedings having been taken by the depart-

ment of Customs and Excise against a Greek merchant trading in London for making a false statement of the contents of some barrels sent by him to Port Said. To quote from the report, "It was observed that at an address near Holborn a number of barrel staves and other parts of barrels were being taken in. Later, twenty empty casks were removed to the place of an earthenware dealer, and subsequently they were sent to Port Said. The specification stated the contents of the barrels to be 'toilet sets,' unrated value £30. The Egyptian Government was communicated with, and on the barrels being examined at Port Said it was found that each of the staves had a slot in which was packed hashish amounting to 456 pieces, and weighing 267 pounds. The consignment was confiscated by the Egyptian Government, and the importer proceeded against under their Customs Act, a fine of £1,215 being imposed. Numbers of staves similar to those in the confiscated barrels were found in the London warehouse, but in a broken condition. It was stated by the prosecuting counsel that hashish could be bought in this country at 9s. for 5 ounces, but in Egypt the same quantity would cost from 25s. to 30s. The defending counsel asked the magistrate to dismiss from his mind 'that hashish was the deadly stuff it was made out to be. It was simply Hemp seed or cake made from Hemp seed, and there was no prohibition in this country. Even a canary might eat as much of it as it liked, and, further, it was not a question of defrauding the revenue.' The full penalty of £100 or three months' imprisonment was imposed."

PROPOSED NEW PARK FOR ABERDEEN.—The proposal to acquire the estate of Keppelstone, to be utilised as a west-end park for the city of Aberdeen, is meeting with general approval. The estate, which extends to about 15 acres, is situated in the environs of the city, partly without and partly within the city boundaries.

THE ANGLO-AMERICAN EXPOSITION.—The following is a programme of conferences to be held during the season at the Anglo-American Exposition, Shepherd's Bush. The conferences will be held at the Palace of Music, commencing each day at 2.30 p.m. —On Wednesday, June 10, the following gentlemen will read papers on hardy plants:—Mr. S. ARNOTT, on "June-flowering hardy perennial plants, natives of America"; Mr. R. W. WALLACE, on "Some aspects of modern gardening." Mr. GEORGE YELD will preside. On Tuesday, June 23, Mr. H. R. DARLINGTON (Vice-President of the National Rose Society) will deliver a lecture on "One hundred years of progress in the development of the Rose"; Mr. E. G. HILL, of Richmond, Indiana, U.S.A., a paper on "The position of the Rose in America." Mr. C. E. SHEA (President of the National Rose Society) will preside on this occasion. On Wednesday, June 3, the conference will be on Sweet Peas. Mr. CHARLES H. CURTIS (late hon. secretary of the Sweet Pea Society) will speak to the subject, "One hundred years' progress with the Sweet Pea in England"; Mr. W. ATLEE BURPEE, U.S.A., will contribute a paper on "The development of the Sweet Pea in America." Mr. LEONARD G. SUTTON will preside. On Thursday, July 16, a conference will be held on forestry, the arrangements for which are not yet complete. The hon. secretary for the forestry section is Mr. WILLIAM DALLIMORE, 43, Leyborne Park, Kew Gardens. On Saturday, July 18, the subject will be border Carnations. Mr. ROBERT MORTON will read a paper on "One hundred years' progress in border Carnations"; Captain SMITH will read a paper on "The cultivation of this plant." Mr. H. R. TAYLOR (chairman of the National Carnation Society) will preside. On Tuesday, August 12, Mr. JAMES

KELWAY will contribute a paper on "The Development of the Gladiolus in England." Papers will also be read on the "Progress of the Gladiolus in the United States." Sir FRANCIS BURDETT will preside. There will be a Dahlia conference on September 2, and the following gentlemen have promised to read papers on this subject:—Mr. GEORGE GORDON (president of the National Dahlia Society), on "One hundred years of progress with the Dahlia in England"; Mr. JOSEPH CHEAL, on "The value of the Dahlia as a decorative plant for the garden and park"; whilst the subject "Progress of the Dahlia in America" will be treated by an authority in America. Mr. GEORGE GORDON will preside. On Thursday, October 1, a paper will be read on "Fruit culture in England," by Mr. E. A. BUNYARD; another on "The development of fruit culture in Ireland," by Sir FRED MOORE; and a paper on "The present position and future prospects of fruit culture in British Columbia." The first Temporary Exhibition was held in a spacious building (No. 21) in the Exposition grounds on May 25, Messrs. G. and W. H. BURCH, of Peterborough, showing an excellent collection of Roses, to which a large Silver Medal was unanimously awarded. On Tuesday, the 26th inst., Mr. J. A. BROWN, Peterborough, showed a large collection of hardy flowering plants. Next week Messrs. KELWAY AND SON, of Langport, will hold a large exhibition of their specialties in the same building. These will be on view the whole of the week, commencing on Tuesday. By holding continued exhibitions of this nature the Executive Committee hope and believe (by reason of promises received) that a permanent exhibition of plants, cut flowers and fruit in season will be held during the time the exhibition is open. Owen Thomas, Hon. Secretary of Horticultural and Arboricultural Committee.

"BOTANICAL MAGAZINE."—The following plants are illustrated and described in the issue of this *Magazine* for May:—

ABIES MAGNIFICA, tab. 8552.—This magnificent Fir is well known in gardens, having been introduced into England so long ago as 1851. The species grows wild in the forest belt of the Sierra Nevada, at an elevation of 6-9,000 feet. At Bayfordbury, Hertfordshire, there is a fine specimen over 60 feet high, with a trunk 6 feet in girth.

ZEPHYRANTHES CARDINALIS.—This is a remarkably handsome plant, with red, funnel-shaped flowers, and thrives under the cultural treatment suitable for *Z. carinata*. The plant flowered at Kew in June, 1893; the bulb had been obtained from the Bahama Islands, where it is cultivated in gardens, but its exact habitat is not known.

MAZUS REPTANS.—This pretty Alpine has been extensively exhibited at recent R.H.S. meetings. It received the Award of Merit of the Floral Committee on March 4, 1913, under the name of *M. rugosus*. Its habit may be likened to that of some of the smaller Lobelias, the prostrate growth making a compact mass which flowers freely.

LONICERA LEDEBOURII.—This shrub, which is of a sturdy, erect character, is a native of California. It bears flowers of a deep orange-yellow colour about the beginning of June, and is very popular as a garden plant in its native country. It was introduced into Britain in 1838, and is common in cultivation, but is often confused with *L. involucrata*.

PITHECOCTENIUM CYNANCHOIDES.—The species described is a native of Brazil and other South American States. It has been in cultivation at Kew since 1834, when the seeds were presented to the Gardens by Dr. DORMER, and it frequently flowers in the summer. It is an attractive twining plant, bearing tubular flowers, which are white on the exterior but yellow inside.

FIG. 170.—MESSRS. SUTTON AND SONS' EXHIBITS AT THE CHELSEA SHOW.

RHODODENDRON EXHIBITION AT WESTMINSTER.

MAY 25-29.—The exhibition of Rhododendrons held during the past few days by Messrs. JOHN WATERER, SONS, AND CRISP, LTD., in the Horticultural Hall, Westminster, created much interest. The large building was filled with a brilliant collection arranged in bold lines and broad masses of colour (see fig. 171). The visitor on entering was confronted with a central group that stretched as far as the opposite wall and extended with undulating fronts on either side almost round to the east and west annexes. Two other large groups, one to the right and the other to the left, were in the body of the Hall, separated from the central mass by pathways, having the effect of sweeping carriage drives, and there were also terraces planted with hardy perennial flowers and Alpines. The most imposing feature was the central bay of the main group, which was composed of a mass of Pink Pearl Rhododendrons, interspersed with standards of Bagshot Ruby varieties, leading to masses of the white and black coloured Sappho,

all three white varieties; Helen Waterer, scarlet with white base; Cynthia, rosy-pink; Strategist, pink; fastuosum flore pleno, the "blue" Rhododendron; and White Pearl. We were pointed out numerous seedlings of great beauty, many being distinct from others in cultivation, but as yet the stocks of these are too scarce for the varieties to be put into commerce. A corner was filled with a striking group, composed of Azalea van Thol, with large salmon-rose coloured blooms. Variety was furnished by groups of other shrubby flowering plants, such as Kalmias, Ericas, and Veronicas.

CHELSEA SHOW.

IN the present issue we publish illustrations of some of the new plants exhibited at the Chelsea Show and described in the last issue.

In fig. 165 is shown the handsome Laelio-Cattleya Medina Excelsior for which Messrs. FLORY AND BLACK received a First-Class Certificate. The flower, in its more Cattleya-like shape and fine colour, shows a marked advance

land in 1890, and many plants of it have been grown during the past twenty years, it remained for Mr. W. H. SMITH, of West Dean Park Gardens, Chichester, to show its full possibilities. The semi-circular group of plants, bearing fully 150 large and richly-coloured spathes, may well be termed the finest exhibit of Richardia Pentlandii that has been staged, and, from the cultivator's point of view, it was a very noteworthy exhibit. Richardias are divided into two natural groups: those in which the leaves are hastate at the base, as in *R. albo-maculata*, and those, such as *R. africana* and *R. Pentlandii*, in which the base of the leaf is cordate; and it is said that *R. Pentlandii* is much the largest-leaved species in the genus. But the plants shown by Mr. SMITH had such exceedingly fine spathes, well set on long stalks, that the foliage by comparison appeared to be small. The story of the introduction of *R. Pentlandii*, of how Mr. Whyte, of Pentland House, Lee, received six tubers from a friend in 1890, with the information that he would probably find a yellow-flowering one amongst them, was told in the *Gardeners' Chronicle* for July 30, 1892, p. 123, by Mr. W. Watson, and another account appeared in the issue for May 12, 1894, p. 590, relating how, in May, 1892, Mr. E. E. Galpin, of Barberton, South Africa, brought to Kew six tubers of a yellow-flowering *Richardia* which had been given him by a gentleman in the Transvaal, who obtained them from a Staats artilleryman, who got them from a Basuto chief whilst on active service. One of the tubers flowered at Kew in 1894, and proved to be identical with Mr. Whyte's *R. Pentlandii*.

As supplementing the report printed last week it should be said that Messrs. T. S. RIVERS AND SONS, Sawbridgeworth, showed fruit trees in pots, including Peach Duke of York, which was raised by them. We have seen good crops on trees of this variety growing against walls in the open in the West of England, and it is well known as a trustworthy early variety for the Peach house. The pot trees shown by Messrs. RIVERS bore fruits almost ripe. Duke of York is a large, well-coloured Peach, and the flesh is of good flavour. Besides Peaches of this variety, this firm showed good Nectarines, Cherries and Plums, which also evidenced the same skilful cultivation.

FIG. 171.—EXHIBITION OF RHODODENDRONS AT THE R.H.S. HALL, WESTMINSTER.

with tall Conifers at the back. Japanese Maples gave the necessary touch of greenery, and our admiration of these splendid foliage plants was equal to our appreciation of the specimen Rhododendrons. The Maples seemed to throw a sheen on the flowers beneath them, making the colours appear softer in the bright sunlight. Of the almost endless number of varieties of Rhododendrons on view, it is difficult to know which to appraise most. Many would acclaim Pink Pearl the gem of the collection, with its trusses of soft pink flowers, that seemed to excel all others in size and grandeur. Others might prefer Alice for its deeper colour, neater habit of growth, and more compact truss. One was heard to give the palm to Gomer Waterer as the Rhododendron of the show, whilst another's fancy was Bagshot Ruby, the finest of all the red varieties, and better even than Doncaster. Where so many are good we can only enumerate a few of those that pleased us most, merely giving the names and their colours as follows:—Prometheus, rosy-crimson; Viscount Powerscourt, rose with very dark blotches; Duchess of Connaught, white and yellow; Mrs. John Clutton, Mme. Carvalho, and Geo. Hardy,

on the earlier Laelio-Cattleyas. *Miltonia vexillaria* J. Gurney Fowler, illustrated in fig. 166, and the beautiful variety "The Baroness" were the two finest plants in the remarkable display of Orchids shown by Messrs. ARMSTRONG AND BROWN. Both plants were exhibited as crosses of *M. vexillaria* Memoria G. D. Owen, the other parent being unnamed; but in the case of *Miltonia* J. Gurney Fowler there seems not to be any departure from *M. vexillaria* Memoria G. D. Owen, and it is one of the best forms of *M. vexillaria*.

Adiantum grossum, fig. 167, shown by Messrs. H. B. MAY AND SONS, is a very desirable addition to decorative Ferns. The handsome green fronds are of thicker substance than those of most *Adiantums*; a desirable quality for cutting.

Iris Goldcrest (fig. 164), shown by Mr. W. R. DYKES, Godalming, received an Award of Merit, and was fully described on p. 363. *Begonia* Lady Carew (fig. 168), shown by Messrs. BLACKMORE AND LANGDON, was one of the best varieties in their remarkable group of these plants.

RICHARDIA PENTLANDII.—Although the "Golden Arum" was introduced from Basuto-

SOCIETIES.

ROYAL HORTICULTURAL SUNDRIES AT CHELSEA.

Our report in the last issue gave particulars of the exhibits of flowers, fruits and other garden produce, and we now publish details of the horticultural sundries, those indispensable mechanical aids to culture, which were exhibited in a special tent.

The exhibits of Messrs. J. CARTER AND Co., Raynes Park, Messrs. J. BENTLEY, LTD., Barrow-on-Humber, Messrs. CORRY AND Co., Covent Garden, PRICE'S PATENT CANDLE Co., Battersea, Messrs. WALTER VOSS AND Co., Millwall, THE BOUNDARY CHEMICAL Co., Liverpool, Messrs. ROBINSON BROS., West Bromwich, Messrs. COOPER AND NEPHEWS, Berkhamsted, and

in size, possess the great advantage of the larger structure. Messrs. J. WEEKS AND Co., Victoria Street, London, displayed fascinating little models of their well-known glasshouses, which embody the latest improvements. Messrs. CHAS. P. KINNELL AND Co., Southwark Street, London, exhibited their well-known boilers. Messrs. HARTLEY AND SUGDEN, Halifax, displayed various heating appliances, and Messrs. HONTSCH AND Co., Twickenham, showed excellent types of hot-house boilers. Garden tools and cutlery were exhibited in a great variety. Messrs. SUTTON AND SONS, Reading, filled a whole length of tabling with a very valuable and interesting collection, in which especial prominence was given to appliances for use on lawns and golf links. A variety of high-class digging and cutting tools, as well as watering appliances, were also on show. Messrs. BARR AND SONS,

CHASE CONTINUOUS CLOCHE Co., LTD., Queen Victoria Street, London, who showed lengths of their handy seed raisers and protectors; and the FRENCH CLOCHE Co., Westminster.

Messrs. H. PATTISSON AND Co., Streatham, demonstrated the ease with which their patent horse boots may be adjusted, and also showed weeding tools and brooms.

Horticultural labels of every shape and size were displayed by Mr. JOHN PINCHES, Camberwell, and there were numerous exhibits of fruit preserves.

ROYAL GARDENERS' ORPHAN FUND. ANNUAL FESTIVAL DINNER.

MAY 21.—The twenty-sixth anniversary dinner of the friends and supporters of this gardening charity was held on the 21st inst. at the Hotel

FIG. 172.—FORMAL GARDEN EXHIBITED BY MESSRS. JAS. CARTER AND CO. AT THE CHELSEA SHOW.

JEYES' SANITARY COMPOUND COMPANY, Cannon Street, London, were interesting and valuable. The spraying appliances of Messrs. H. HARTJEN AND Co., Noble Street, London, THE FOUR OAKS SPRAYING Co., Sutton Coldfield, and Messrs. G. W. PERSER, LTD., Hatton Garden, London, comprised a variety of ingenious contrivances. The "Holder" sprayer, shown by Messrs. HARTJEN, permits the free use of both hands, and is especially commendable.

An interesting mechanical novelty in the show was the Pullen Burry Transverse Travelling Hothouse. Examples were shown just inside the Sloane Square entrance, where an attendant demonstrated the ease with which the structures can be moved, and indicated their horticultural value. Besides an example of the hothouse described in the *Gardeners' Chronicle* of April 12, 1913, Messrs. PULLEN BURRY exhibited an amateur's greenhouse, and an "Ideal" travelling frame, both of which, though smaller

Covent Garden, London, also showed many useful tools; their bulb-planting implements are unique and valuable. Mr. V. T. HILL, Langford, Bristol, showed the V.T.H. patent slug trap, which provides an effectual means of catching these pests.

Garden furniture and ornaments were shown in great variety, and many of the summer-houses were of excellent design. The chief exhibitors were THE LONDON, PROVINCIAL AND EXPORT BUILDING Co., Hull; Messrs. J. USHE AND Co., Edgware Road, London; THE DRYAD WORKS Co., Leicester; Mr. J. BRADLEY, Derby (The "Bunty" Garden Tea House); Messrs. NIPAN AND HEADLEY, Leicester; and Mr. H. E. WEMYSS, London. Messrs. C. H. PULLEN, LTD., Derby, showed examples of wood preservatives, and THE GARDEN CITY TRUG Co., Fleet, Hants, exhibited well-made trug baskets, some of them being fitted for carrying tools. French gardening appliances were displayed by the

Cecil, Strand. Baron Bruno Schröder was in the chair and presided over a large gathering. Among those present were Sir Harry J. Veitch, Col. Mark Lockwood, M.P., Col. S. J. Smith-Young, Dr. F. W. Keeble, F.R.S., E. Rochford, Thomas Cox, H. Morgan Veitch, E. Manwaring, W. E. Cluncher, W. A. Bilney, N. N. Sherwood, W. J. Jefferies, Edward Sherwood, Leonard G. Sutton, Martin H. F. Sutton, Edward White, R. Hooper Pearson, J. B. Slade, G. J. Ingram, P. Rudolph Barr, Geo. H. Barr, Donald Anderson, Jas. T. Anderson, E. C. Anderson, G. H. Cuthbert, R. G. Cuthbert, W. Pomart, J. F. McLeod, H. B. May, and D. Inghamells.

The chairman gave the usual loyal toasts, which were received with musical honours, after which he proposed the toast of the evening, "The Royal Gardeners' Orphan Fund." It was, he said, a great pleasure to be present in the capacity of chairman at the festival dinner,

although when then chairman, Mr. May, asked him to preside he felt reluctance in accepting such a responsible position. Not only (he continued) was gardening the oldest profession in the world, it was also the most important, for we may regard agriculture as a branch of gardening, and without agriculture there could be no food and industry would be impossible. The development of every country begins with the cultivation of the land. Apart from its antiquity and utility gardening was also the greatest pleasure a man could enjoy. In England this was especially so, for whether in large towns, suburbs, villages, or hamlets, one could everywhere see the intense love of the Britisher for his garden. To night all thoughts were turned towards the professional gardener, who spent his

sent year £1,868 had been dispensed, and £150 had been paid, at the discretion of the committee, on providing outfits for children leaving the fund and beginning to work. During the past two years it had been possible to place on the funds all children seeking admission; but they could not expect that they would always be enabled to do this, and this year already there were sixteen waiting to be placed in the list next year. The annual subscriptions amount to only £450, leaving more than £1,000 to be made up by voluntary donations. The thanks of the committee were especially due to Lady Ilchester and Sir Frank Crisp, who had been good enough to help the institution by throwing open their grounds to the public for a small fee, and also to the gardening societies and local sec-

tion of the privilege. He spoke of the great honour in which the name of Baron Schröder was held in all gardening circles, and of the fact that it was in great measure due to the late Baron that the R.H.S. now possessed its splendid hall. Baron Schröder then replied briefly with a few words of thanks, and referred to the pleasure it had given him to be among them and to hear such good news of the work of the fund.

The secretary, Mr. Brian Wynne, then announced that the sum subscribed during the evening amounted to a little over £1,200. The principal sums included £100 from the chairman, Baron Bruno Schröder; N. N. Sherwood and his sons, £100; Sir Frank Crisp, Bart., £62; Messrs. Sutton and Sons, £50; Messrs. Rothschild and Sons, £26 5s.; Frank C. Marks, £25; Anthony

FIG. 173.—CINERARIAS AND PRIMULAS EXHIBITED BY MESSRS. ED. WEBB AND SONS AT THE CHELSEA SHOW.

life in ministering to the pleasure of those for whom he worked. If such a man was taken from us in the prime of life, was it not our duty to care for the orphans he leaves behind? This work was done in a splendid manner by the R.G.O.F. There was no more praiseworthy work than aiding the orphan and fatherless; indeed, it was a national duty to support the young, on whose health and efficiency the future depended. He had great pleasure in giving the toast of the fund, coupling with it the name of the treasurer, Mr. Edward Sherwood.

Mr. Sherwood, in reply, said that he had great pleasure in announcing that the fund continued to prosper. Its usefulness became more and more apparent, and the number of applicants greater every year. Nearly £30,000 had been subscribed since it was founded. During the pre-

retaries who had been indefatigable in collecting donations. The shilling subscription fund had this year met with unprecedented success, and it was hoped that it might assume large proportions. He had pleasure in seconding the appeal of the chairman for support of this eminently useful charity.

Mr. N. N. Sherwood proposed the toast of "The Visitors," and appealed to those present to continue to aid in the good work which was being done. He asked them to do their best to support the charity and make it an abiding success. Mr. W. J. Jefferies replied for the visitors, and expressed the great pleasure it gave to him and to all those present to hear such a satisfactory account of the activities of the society. Mr. H. B. May proposed the toast of "The Chairman," and expressed his apprecia-

Waterer, £25; R. B. Leech, £29 18s. 6d.; G. H. Cuthbert, £27 15s.; Sir Jeremiah Colman, Bart., £20; J. F. McLeod, £20; Whitpaine Nutting, 18 guineas; R. Hooper Pearson, £17 (including 5 guineas from the proprietors of the *Gardeners' Chronicle*); David W. Thomson, £15 9s.; W. Ponpart, £14 12s.; J. W. Blackburne, £12; F. C. Stanisby, £11; Sir Edgar Speyer, Bart., £10 10s.; Messrs. James Carter and Co., £10 10s.; Messrs. Barr and Sons, £10 10s.; Messrs. G. Bunyard and Co., Ltd., £10 10s.; Wm. Howe, £10 10s.; Edward White, £10 10s.; A. W. Metcalfe, £10 10s.; Sir Harry Veitch, £10 10s.; J. C. Geiselbrecht, £10; Leonard Sutton, £10; Martin H. F. Sutton, £10; Thomas Hay, £9 7s.; H. B. May, £7 7s.; G. Caselton, £7 7s.; T. A. Morris, £6 6s.; T. W. Sanders, £6 6s.

The following each subscribed 5 guineas:—Lady Veitch, Mrs. Tiarks, Reg. R. Cory, L. Foersheim, John Margetson, E. Mainwaring, C. A. Bingel, W. J. Jefferies, Osman and Co., Ltd., Dr. F. Keeble, F.R.S., Col. M. Lockwood, M.P., W. G. Churcher, Corry and Co., Ltd., W. Cuthbush and Sons, J. T. Anderson and Sons, Ltd.

The sum of £5 was contributed by Thos. H. Mann, J. L. Walker and W. A. Bilney.

Covent Garden growers subscribed £170, collected by Mr. D. Ingamells, including Mr. Edmund Rochford, £10; Mr. Jesse F. Smith, £6 6s.; and 5 guineas each from Mr. James Sweet, Mr. John Rochford, Mr. Joseph Rochford, Mr. H. O. Larsen, Mr. O. Hiehle, Mr. J. Collingridge, J. C. Mee, Mr. G. E. Messer, Messrs. Forster and Robins, and Messrs. C. P. Kinnell and Co., Ltd.

The tables and orchestral platform were beautifully decorated with flowers contributed by the kindness of Sir Harry J. Veitch, Mr. T. Rochford, Mr. G. H. Barr, Mr. T. S. Ware, Mr. A. F. Dutton, Mr. C. Engelmann, and Messrs. Lowe and Shawyer.

The musical programme, which was interspersed with the toasts, was excellent.

HORTICULTURAL TRADES' ASSOCIATION.

DINNER TO SIR HARRY J. VEITCH.

MAY 19.—As announced in our last issue, the members of the Horticultural Trades' Association of Great Britain and Ireland entertained Sir Harry Veitch at dinner at the Hotel Windsor on the above date. The President for the year, Mr. William Cuthbertson, was in the chair, and there was a company present of about eighty.

After the loyal toasts had been duly observed, the President set forth the programme for the evening, by stating that it had been arranged that several members who had been associated with Sir Harry Veitch for a considerable number of years should speak to the toast of his health, which he, the President, had now the privilege of proposing. He referred in the highest terms to the feelings entertained for their guest, and he was sure that the toast would meet with their hearty approval.

The next speaker was Mr. George Paul, one of Sir Harry's oldest friends in the horticultural trade. He stated that their acquaintanceship commenced in 1856, when they were fellow students at the same school at Altona, in Germany, and they had been in touch with each other during the whole period of fifty-eight years that had since elapsed. He was exceedingly proud of the opportunity of standing up before an assembly such as was present that night to testify to the respect he, in common with all horticulturists, felt for Sir Harry Veitch. They had long since recognised Sir Harry as the leading figure in the horticultural trade, and he was glad to be able to say that Sir Harry had always been ready to give advice and help to any of his colleagues who had occasion to seek his assistance. The firm of Veitch was a remarkable business; they often wondered how it was that the firm had been so successful. After speaking of some of the methods that had contributed to their success, Mr. Paul claimed that the firm owed its position no less to its enterprise than to its straightforwardness and integrity.

Mr. N. N. Sherwood, the next speaker, referred more particularly to Sir Harry Veitch's work in connection with the Gardeners' Royal Benevolent Institution, and to his liberal assistance of other charities; also to his interest in religious work, in the prosecution of which he spent considerable time and energy. He said that Sir Harry had been blessed with prosperity, but he had not neglected to help those who had been less blessed than himself.

Mr. Charles E. Pearson, in supporting the toast of the evening, pointed out that Sir Harry was one of the very few successful men who had made no enemies. The firm of James Veitch and Sons was a business that they might all envy, but it was a business of which none could complain, for the success had been obtained by methods that were not open to objection. Sir Harry had achieved his position by hard work, ability, and honesty of purpose. No one in the horticultural trade was jealous of the position

he had obtained, and every one of them rejoiced that he had achieved that position.

Mr. David W. Thomson, who also supported the toast, confined his remarks more or less to reminiscences of the Chelsea nurseries. He stated that he commenced work at those nurseries on May 13, 1873, at six o'clock in the morning, and he was admitted by John Dominy. Mr. Thomson caused considerable amusement by referring to the pot-washing and croeking that he had to perform under Mr. May, one of the foremen, and afterwards proceeded to speak of one foreman after another, until a whole list had been mentioned, and in each case

they could all appreciate the high motives that had led Sir Harry to adopt the course upon which he had decided.

The toast was drunk with musical honours, and Sir Harry Veitch responded in an able and profoundly interesting speech. He started by referring to his great-grandfather, who left Scotland in 1775 to become steward at Kilmington, in Devonshire. After serving in this position for a considerable number of years, the owner of that estate was so satisfied with the service that had been given him that he told Veitch that he might choose any farm on the estate and have it, rent free, for the remainder of his

FIG. 174.—SHINTO TEMPLE AND WISTARIA IN THE "JAPANESE" GARDEN EXHIBED BY THE YOKOHAMA NURSERY COMPANY AT THE CHELSEA SHOW.

Mr. Thomson stated that "he had passed away." He concluded with a fine tribute to the position attained by the firm of Veitch: "They may ring down the curtain at Chelsea, take down the sign and close the gates through which so many have passed on their way to success, but the name of Veitch will live long after the present generation has passed away, and will be handed down to generations yet unborn."

The President, in putting the toast, referred to Sir Harry Veitch's decision not to sell the good-will of the Veitchian business. He said it was a noble action; it did not appear to be in agreement with general business principles, but

days whilst he retained his stewardship. He commenced to cultivate horticultural crops on this land, and this was the commencement of the business which was started at Exeter, and afterwards extended to London. Many were interested and some consoled to hear that Sir Harry's grandfather smoked thirty pipes of tobacco a day, and lived to the age of 85 years.

Surveying horticulture during the past sixty-three years, Sir Harry asked the company to consider how many nursery businesses had ceased to exist in that time: it showed what extraordinary changes were going on. Amongst others were those of Chandler, Milne, Rollisson, Henderson, Osborne, Kinghorn, Lee of Ham-

mersmith, Parker, Jackson, Standish, Noble, Luckcombe, F.ince and Co. (Exeter), Herbst, Palmer, Garraway of Bristol, and Smith's of Worcester. There were doubtless others, but these were sufficient to show the ups and downs that occur even in such a business as the nursery and seed trade.

After referring to the exhibition of 1851, Sir Harry proceeded to relate interesting facts concerning the discovery, propagation, and sale of those new plants which had gone a considerable way towards helping to establish the business. Among others he mentioned *Berberis Darwinii* and *Medinilla magnifica* (easily disposed of at three guineas a plant). In 1860 John Gould Veitch went to Japan, and the collections he made there provided the firm with a wonderful number of novelties, including the ever-popular *Ampelopsis Veitchii*, which now rejoices in thirteen names.

In 1862 Sir Harry visited for the first time the Ghent Quinquennial Exhibition, where his

early days, Sir Harry stated that *Pandanus Veitchii* was shown six times before that committee gave it an award.

In 1867 Sir Harry went to Paris for an important exhibition; 1867 was remarkable for the sale of Bause's seedling *Coleus* at Stevens' Auction Rooms. Sir Harry was deputed by his father to go and examine these *Coleus*, and he bought six of them for £261 4s., and these six plants afterwards gained six First-class Certificates.

In 1869 he went to St. Petersburg, taking with him *Masdevallia Veitchii*, and keeping it in the railway carriage with him, so valuable a novelty was it in those days. About this time the propagation and cross-breeding of *Begonias* was commenced, and the Golden Hamburg Grape was introduced; also *Asparagus plumosus*. Later the hybridisation of Orchids became more and more part of the work engaging the attention of the firm. The Java *Rhododendrons* were also

the President, in replying, stated that the meeting would be adjourned until September 9, in Edinburgh.

KEW GUILD.

ANNUAL MEETING AND DINNER.

MAY 20.—There was a large attendance at the annual general meeting of the Kew Guild which was held at the Holborn Restaurant on May 20. The report and balance-sheet, both of which record satisfactory states of affairs, were adopted unanimously. The members of the committee who retire under rule 4 are Messrs. W. Hales, R. L. Harrow, R. A. Rolfe, and J. Weathers; their places were filled by the election of Messrs. Chas. H. Curtis, F. W. Harvey, A. Hosking, and J. Hutchinson, whilst Messrs. G. F. Glover and C. Boff were elected by the sub-foreman as gardeners. Messrs. A. Osborn and E. Allard are the auditors for the ensuing year. Mr. J. Coutts was re-elected treasurer and Mr. H. Cowley, secretary and editor. The

FIG. 175.—WISTARIA GARDEN EXHIBITED BY MESSRS. PIPER'S AT THE CHELSEA SHOW.

firm showed as a new plant *Alocasia Veitchii*. The same year the firm flowered *Lilium auratum*, Sir Harry relating some very interesting particulars of the manner in which his firm outdid Fortune, who was collecting *L. auratum* for another firm. Mr. James Veitch purchased a large number of *auratum* bulbs at a sale in London, when there was a considerable doubt as to the identity of the bulbs, but they all turned out true.

In 1865 he attended an International Exhibition at Amsterdam. He and one or two others, led by Dr. Masters, invited the foreign nurserymen present at Amsterdam to come to London in the following year, and they would promote an International Exhibition in London. This was the origin of the International Exhibition of 1866, a solitary event of its kind until 1912.

John Gould Veitch returned home from his second trip, which was to the South Sea Islands, in 1865, bringing with him many *Crotons* and *Dracaenas*, and that wonderfully fine plant *Pandanus Veitchii*. In testimony of the discrimination of the Floral Committee in those

hybridised, and Sir Harry stated how, by selecting petaloid flowers for four generations, a variety was obtained with perfectly double flowers.

In regard to Orchids, Sir Harry said that the company knew well enough that the first hybrid was raised by Dominy. He was inclined to think that the paper which he himself read at the Orchid Conference in 1885 had the effect of giving a great impetus to cross-breeding of Orchids in this country.

Sir Harry concluded his speech by giving some amusing particulars of the regulations in the old days of the Chelsea Nurseries, and stated that the young men were compelled to be clean-shaven.

The toast of the United Horticultural Trades Association was proposed by Mr. Arthur W. Sutton in an appropriate speech, in which he not only spoke of the value of the work the Association is doing, but also of the high character and attainments of Sir Harry Veitch.

The concluding toast was that of "The President," proposed by Mr. Alfred Watkins, and

secretary reported that the special appeal made on behalf of Mr. W. Crisp, who was for so many years packer at Kew, has already met with a ready response, but further subscriptions are needed.

Mr. A. W. Hill, M.A., presided at the annual dinner, at which 100 members were present, and the visitors were Sir Frederick Moore, M.A., M.V.H., Colonel Gage, and Mr. J. R. Jackson. Three lady members, the Misses Cope, Gunnell, and Powell, attended, and amongst the members present from abroad were Messrs. H. A. Cannon and T. Hunter (Gold Coast), G. T. Lane, and J. T. Johnson (Calcutta), F. S. Sillitoe (Khartoum), C. B. Usher (Java), and A. H. S. White (E.S.A.).

Mr. C. H. Curtis was deputed to convey the greetings of the Kew Guild to the Carnation Society, who were also dining in the Holborn Restaurant, which greetings were heartily reciprocated.

In proposing "The Kew Guild," Sir Frederick Moore said that his great pleasure in being invited to the dinner was tinged with the

sincere regret that he was not a Kewite. He had often wished that his father had sent him to Kew in his young days instead of to the Continent, for he was convinced from his personal experience that the home horticulture was superior to that abroad, and, speaking from a wide knowledge, Kew was the finest garden in the world. The advantages which Kew offered to her young men were enormous, and he felt sure that this was appreciated by the "Present Kewites." Consider, he said, the staff at Kew—Sir David Prain, the director, who is a wonderful botanist; Mr. Watson, the curator, whose knowledge of plants is unequalled in Europe. Hand him a plant and he will quickly tell you its value and possibilities. To mention only one plant, the *Streptocarpus* of to-day is due to Mr. Watson's intuitive knowledge and foresight; Mr. Bean amongst trees and shrubs, and Mr. Irving in the rock garden are also the leading authorities of the day—no other garden possesses such men. Everything changes, and gardening is no exception; the collections of stove plants have gone, he continued, and in their place we have houses of Carnations, Roses and other plants; whilst in the out-door garden the greatest change is to be seen in the rock garden—such as those wonderful gardens which we have seen at Chelsea. Sir Frederick then spoke of the enormous value of practical experience, and said that it was only by working amongst plants that one could really know them. He was glad to know that the Kew Guild had a Benevolent Fund, for to help their members is the true spirit of a Guild. "No man has a right to take a step up the ladder without holding out a hand to him below." In conclusion he said it was inevitable, but there was a tragic page in the *Journal*; the photographs and records of those members who had gone, some of them pioneers who had, whilst yet young, laid down their lives in the service of their country.

In responding to the toast, Mr. A. W. Hill expressed the honour which the Guild felt at the presence of Sir Frederick Moore, and their pleasure in his speech. He briefly reviewed the reasons of the Guild's existence, and was sure it did good work in welding the bond of friendship around the whole world. He endorsed Sir Frederick's remarks concerning the great value of practical experience, and quoted Aristotle, "If you want to learn to play the harp you must play the harp." Mr. W. Hales proposed the health of the new President, Mr. W. J. Bean, and referred to his great accomplishments and to the esteem in which he is held by the members. Mr. Bean briefly replied.

PERPETUAL-FLOWERING CARNATION.

MAY 20.—The annual dinner of the members of this society was held at the Holborn Restaurant on Wednesday, the 20th inst., Mr. J. S. Brunton presiding. About 60 members and friends were present. After the usual loyal toasts had been given and honoured, Mr. George Monro, junr., gave the toast of "The Perpetual-Flowering Carnation Society." He said that the Perpetual-Flowering Carnation had become popular quickly. Exhibitions, said Mr. Monro, have done more to popularise the flower than anything else, and each provincial show has been followed by a greater demand for the flower.

Mr. J. S. Brunton, who replied, referred to the valuable help rendered to the society by the officers and committee.

Greetings were exchanged between the members of the Kew Guild, who were also meeting at dinner in the same building. Other toasts included "The Ladies," proposed by Mr. H. T. Mason, and responded to by Mr. Taudevin; "The Visitors," by Mr. C. Engelmann; "The Dinner Committee and Artists," by Mr. L. J. Cook; and "The Chairman," by Mr. W. H. Page.

CARDIFF GARDENERS'.

FORTY of the members of this association, many accompanied by ladies, recently visited "Lynwood," Penarth, the residence of the President, Mr. J. J. Neale. The visitors were conducted by Mr. Neale through the gardens, where they greatly admired the Orchids and insectivorous plants.

MARKETS.

COVENT GARDEN, May 27.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

Cut Flowers, &c.: Average Wholesale Prices.

—short	1 0-1 3	—White Crawford	2 0-3 0
Lily-of-the-Valley, per dozen bunches:		—Yellow Souvenir	1 6-2 6
—extra special	12 0-15 0	Spiraea, per doz. bunches	5 0-6 0
—special	9 0-10 0	Statice, manve, per doz. bunches	3 0-4 0
—ordinary	8 0-9 0	Stephanotis, per 72 pips	1 6-2 0
Marguerites, per dozen bunches	1 6-2 0	Stocks, English, white, per doz. bunches	4 0-6 0
Mignonette, per dozen bunches	3 0-4 0	—coloured	5 0-6 0
Narcissus, Poeticus, per doz. bun.	2 6-3 0	Sweet Peas, white and coloured, per doz. bun.	3 0-10 0

REMARKS.—Business in cut flowers is only moderate, the best days for trade being Tuesday and Saturday. Supplies of Pyrethrum have increased considerably, both double and single; the double white variety is most in demand. The prices of double white Narcissus have advanced, for these flowers are now nearly over. Blue, white and pink Cornflowers are arriving in a splendid condition, as are Gladioli The Bride (white) and Carnations, which are more plentiful. The chief varieties of Carnations are Enchantress, May Day, Britannia, Scarlet Glow, Beacon, Winsor, White Perfection, White Enchantress, Mrs. Burnett, R. F. Felton and Mikado. Liliun Harrisonii is very cheap, but prices will increase towards the end of the week; this also applies to scarlet Pelargoniums (Geranium) and other scarlet flowers, which will be wanted for church decorations. During this week scarlet "Geranium" usually realises its highest value.

REMARKS.—Nine thousand cases of Australian Apples have come to hand per a.s. "Orsova," and a few Grapes and Pears arrived by the same boat. A few fruit is now at an end. Forced Strawberries continue to be plentiful; a few from out-of-doors from Southampton and Cornwall arrived this week, and France is also contributing to the supply. A few small punnets of Raspberries have been received this week. Some very fine fruits of Cherries are arriving from France daily, packed in small boxes, and Apricots are arriving from the same country. Green Figs and Melons are plentiful. Nectarines and Peaches from English and Continental growers are daily increasing in supply. English Grapes are increasing in quantity daily and show a decided improvement in quality. Good samples of Gooseberries are obtainable. Supplies of Tomatoes and Cucumbers from home growers are beginning to increase.—E. H. R., Covent Garden, May 27, 1914.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending May 27, 1914.

A Sudden Change to Colder Weather.—The recent warm period lasted ten days, and terminated on the 23rd, since which time the weather has been very cold for the time of year. Between the 22nd and 25th the maximum shade temperature fell from 77° to 54°—a fall of 23°. On the last two nights the exposed thermometer has registered respectively 8° and 9° of frost. The ground is now 1° warmer at 2 feet deep, but 2° colder at 1 foot deep, than is seasonable. Rain fell on two days, but to the total depth of only one-tenth of an inch. There has been no percolation through either of the soil gauges for nearly a fortnight. The sun shone during the week on an average for eight hours a day, which is two hours a day longer than is usual at the end of May. On one day the sun was shining brightly for 13½ hours. Light airs and calms alone prevailed during the week. For the first three days the direction of these light airs was some point between south and west, but since then they have come from some point between north and east. The mean amount of moisture in the air at three o'clock in the afternoon exceeded a seasonable quantity for that hour by 3 per cent. A large bush of the wild Dog Rose came first into flower in my garden on the 26th inst., which is nine days earlier than its average date in the previous 28 years, and, with one exception, 1693, earlier than in either of those years.—E. M., Berkhamsted, May 27.

Obituary.

LAWRENCE DAVENPORT.—We learn from the *American Florist* the news of the death, on April 18, at the age of 78, of Lawrence Davenport, a native of Chorley, Lancashire. Mr. Davenport emigrated to Lawrence, Mass., U.S.A., at an early age, where he engaged in the pursuit of horticulture. He died in the same town, having lived there since 1864.

PETER ROSS.—The death is announced in the *American Florist* of Peter Ross, who was born at Balmagown, Scotland, in 1851. He emigrated early in life to America, and pursued the business of a florist. He settled in Flushing, L.I., and died there on April 27 last.

JOHN SCOTT.—From the American publication, *Horticulture*, comes the news of the death, on May 2, of John Scott, a native of Haddington, N.B. Mr. Scott was an expert gardener of the old school, and had been employed on the estate of the Earl of Dalkeith for over forty years. He finally emigrated to Brooklyn, N.Y., and died there.

BAY LEAVES DISEASED: W. T. M. The Bay shrubs are infested with a fungus known as *Capnodium mangiferum*. The fungus is nourished on the "honey-dew" secreted by aphides, or green flies, and the trees should be well sprayed with an insecticide in order to destroy these insects. When they are no longer present the fungus will die away for lack of encouragement.

BEDDING SCHEMES: A Head Gardener. The undernoted are all effective. For two-colour schemes, groups, or beds: Blue and white; blue and cream; blue and pink; blue and crimson; purple and red; purple and crimson; purple and mauve; purple and white; purple and golden yellow; purple and orange; purple and cream; pink and mauve; pink and lavender; pink and cream; pink and violet; rose and cream; rose and crimson; rose and lavender; yellow and orange; yellow and brown; deep yellow and greeny-white; deep yellow and rose; lavender and creamy lavender and rose. For three-colour schemes: Rosy carmine, pink and mauve; deep crimson, dark blue and lemon; white, blue and crimson; brown, orange and yellow; blue, lemon and white of yellow tint; violet, light blue and pink; salmon, light blue, and pink or cream; dark blue, light blue, and white or cream; purple, mauve and lemon. Mixtures of pink to crimson with blue are satisfactory. One-colour arrangements are accentuated by employing similar plants of different heights—e.g., tall with dwarf *Ageratums*; tall carmine with intermediate carmine *Antirrhinums*, and the tones may be dissimilar as well as the heights—e.g., dark yellow intermediate *Antirrhinums* with tall yellow varieties several shades lighter. Or the plants may be of different kinds as well as different heights—e.g., *Anchusa Dropmore* variety, tall crimson *Lobelia*, and cream *Antirrhinum* or *Ostrich Plume Aster*; deep rose stock-flowered *Larkspurs*, *Lavender* or *Nepeta Mussinii*, and *Pearl Nasturtium*. The newer *Gladioli* of art shades afford splendid material for working among flatter growing plants. The above are examples of the simplest, and at the same time most effective, ways of employing decorative plants for flower gardening. They are certain to give satisfaction, provided the plants are well grown and properly attended throughout the season. The choice of plants ranges through annuals, biennials, and hardy and tender plants of almost endless variety.

FIGS FAILING TO MATURE: W. T. H. There is nothing the matter with the Figs you send for examination. The only reason for their dropping is that they have been forced too early in the season for the flowers to have been fertilised. The "fruits" form and grow to a certain size, but without fertilisation they subsequently drop without becoming ripe.

GRAPE DISEASED: W. B. The berries are affected with spot disease, caused by the fungus *Gloeosporium ampelophagum*. Dredge the vines with flowers of sulphur at intervals of ten days. On the second occasion add a small quantity of quicklime to the sulphur, and increase the quantity on each successive application, but always use a little more sulphur than lime. Next winter, when the vine is resting, drench the rod with a solution of sulphate of iron. Collect and burn all diseased leaves, shoots, and fruit.

LILAC: W. H. W. We do not recognise the variety of Lilac. Send a specimen to some nurseryman, who can compare your variety with those in his collection.

NAME OF FUNGUS: L. C. S. The plant sent is not a fungus, but one of the *Myxogastres*. It arrived in a damaged condition, and hence we cannot give you more detailed information.

NAMES OF PLANTS: R. 1, *Erythronium* sp., and 2, *Papaver* sp. (too much faded to identify); 3, *Ranunculus aconitifolius* var. *flore pleno*; 4, *Trollius asiaticus*; 5, *Tiarella cordifolius*; 6,

Leucojum aestivum. On another occasion, please send better specimens.—P. A. *Saint-paulia ionantha*.—*Dawn Farm, Westonbirt*. 1 and 2, *Abies brachyphylla*; 3, *Corylus* sp.; send when in fruit.—W. R. P. 1, *Asparagus scandens*; 2, *Rhododendron calophyllum*.—Lynn. 1, *Saxifraga Sibthorpii*; 2, *Fuchsia fulgens*; 3, *Begonia fuchsoides*.—E. F. *Dendrobium lituiflorum*.—C. F. C. We do not recognise the variety of Horse Chestnut. The stove plant is *Ruellia Portellae*.—G. H. L. 1, *Cercis Siliquastrum* (*Judas Tree*); 2, *Cistus florentinus*; 3, *Ceanothus Veitchianus*; 4, *Teucrium fruticosum*; 5, *Eschscholtzia californica*; 6, *Trachelospermum* (*Rhynchospermum*) *jasmuinoides*.—V. *incent*. 1, *Muscari comosum* var. *plumosum*; 2, *Valeriana Phu*.—*Orchid*. 1, *Cattleya Forbesii*; 2, *Laelia Boothiana*; 3, *Eria tricolor*; 4, *E. convallarioides*.—J. T. *Dendrobium suavissimum*.—*Mimulus*. *Mimulus cupreus*; not rare.—W. H. S. 1, *Vanda Bensonii*; 2, *Cymbidium pendulum*.—W. Parker. *Eccremocarpos scaber*.

PROPAGATION OF DAHLIAS: H. S. Dahlias are very easily rooted. Detach a little of the fleshy tuber with the individual cuttings when about 2 inches high, and insert them singly in 60-sized pots filled with light mould, and surfaced with sand. If watered and kept close in a uniformly moist atmosphere 95 if not 100 per cent. of the cuttings will become rooted within a week or two.

ROSES FAILING: Enquirer, Swansea. The Roses are apparently suffering from the presence of crown-gall, or tumours at the collar or roots. The roots should be exposed and the swellings removed, afterwards carefully covering the wounds thus made with gas-tar. The roots should then be re-covered with suitable soil, and the symptoms will probably cease.

SEEDLING RHODODENDRON: W. C. Midford. Your seedling *Rhododendron* is pretty, but it is not distinct or superior to others already in cultivation of the same colour and showing similar markings. It would therefore have little commercial value.

STRAWBERRIES FAILING TO SET: G. J. Your Strawberries are quite healthy, but they have not been fertilised. Under such circumstances the fruit will not set or swell, and the flowers, after blooming for a while, naturally die.

SWEET PEAS: Bathonian. The roots and stems of the Sweet Peas seem to be perfectly healthy, but the lower leaves look as though they had been eaten by small slugs, which often make the leaves appear skeletonised, the tissue of the under side of the leaves being eaten and the top skin of the leaf shrivelling. One pair of leaves only is burnt on the outside edges, and this is quite distinct from the injury to the lower leaves and might be caused by frost after a damp evening, or to fresh soot sprinkled over them. On the whole we are inclined to think that the injury is caused by unsuitability of cultivation rather than by disease.

TULIPS FOR PROPAGATION: W. T. Allow the bulbs to remain in the ground until all the leaves have died, then lift them all carefully, including the very small ones. Place them in a cool, airy shed, and when dry clean all the soil and loose materials from them with the fingers. In August prepare a plot of ground by manuring with farmyard manure and digging the same well below the surface; early in October plant the Tulips in rows at 1 foot apart, and 6 inches between the bulbs in the rows; the small bulbs may be placed at half the above distances to economise the space.

VINES WITHERING: P. G. W. Examination of the specimens sent failed to disclose any trace of disease. The cause of the withering is probably the absence of sufficient moisture at the root.

THE MARKET FRUIT GARDEN.

MAY has proved a month of disaster to fruit-growers and market growers of vegetables throughout a great portion of the country. Large proportions of the Plum, Pear, and early Apple crops were destroyed by the very severe frost which occurred early on the morning of May 2, while Plums, Pears, and Apples to a less extent were further swept away by the frosts which occurred towards the end of the month, the Strawberry crop in some districts being almost entirely destroyed by the later frosts. Comparatively little damage is reported in relation to Gooseberries and Currants, and no mention of decided injury to Cherries has come under my notice. Apparently no great severity of frost occurred in Kent, and a visit to a few districts in that county has not disclosed to me any serious injury to fruit of any kind. Further south, in the Southampton district, however, the Strawberry crop has been greatly damaged. For my own part, no frost has been registered in my orchards since March. The losses incurred by growers in the neighbourhoods of Evesham, Pershore, Wisbech, and great fruit districts further north, are lamentable, and all the more so after the splendid prospect which was presented at the end of April. By way of counterblast to my happy escape from frost, I have been an exceptional sufferer

from drought, having had much less rain than even the small quantity credited to the south-east of England as a whole. From April 11 to noon on May 31, just over seven weeks, my rainfall was only 0.40in.

RESULTS OF THE DROUGHT.

Perhaps the worst result of the drought is the running off of Black Currants, which appears to have been very serious in some districts. Promise of a crop in my orchards was uncommonly good a fortnight ago. It is less good now, but not as bad as might have been expected. Another result of the drought is the failure of the Gooseberries to swell to their proper size. Probably the drought may also be held accountable for the large numbers of Plums which have dropped. Similarly the withering of whole trusses of Apple blossom, which is more common than usual on some varieties, is partly due to the lack of a sufficient supply of sap, which may be traced to the drought. Lastly, there is to notice the extreme difficulty of hoeing the orchards, either by horse or hand power, and the great extra expense of such work as has been done. Against this may be set the lack of the usual growth of weeds, and their speedy destruction when chopped out of the land by the hoe; also the checking of such fungous diseases as brown rot of Plums, Apples, and Cherries, which would have been prevalent if a wet April and May had succeeded the rainy winter and the March deluge.

LADY-BIRDS AND APHIDES.

Mr. A. J. Bliss's suggestion on page 374 that it might be worth while to attempt the breeding of lady-birds as devourers of aphides is worth consideration. But we need to know the conditions under which, what may be called, the intensive culture of lady-birds can be carried on. Last year, when aphid infestation was very extensive, I found great numbers of lady-birds. This season, when I have had no aphides worth notice on Apples, and extremely few on Plums, I have hardly seen a lady-bird or its larva, the "nigger," although I have examined a great number of trusses of blossom and of fruitlets after the blossom had fallen. This is a curious coincidence, and one that raises three questions:—(1) Where does the lady-bird deposit her eggs? (2) If on the trees and bushes upon which she fed on aphides in the spring and summer, how is the dearth of this insect in my orchards this season to be explained? (3) If elsewhere, in what directions should we look for the lady-birds? Apparently, the lady-bird does not feed on apple suckers, which were more numerous this season in my orchards than they have ever been before. It would be well worth while to ascertain by precise experiments to what extent an aphid wash kills lady-birds. I fear it kills some, as I have found dead ones, and it probably kills more "niggers." In spraying against suckers one necessarily sprays also against aphides. But I do not think that the extreme rarity of lady-birds this season can be accounted for by supposing that last year's broods were nearly exterminated by spraying, be-

cause I find the scarcity in young plantations which were not sprayed for sucker or aphid in 1913 or this season. Some other natural enemies of the aphid are probably killed by spraying. But it is hardly possible that a wash fatal to aphides and suckers and harmless to their natural enemies can be discovered. The only hope in this direction seems to lie in taking care to use a wash no stronger than the weakest which is fatal to aphides and suckers. A paragraph below incidentally bears upon this point.

MORE ABOUT THE APPLE SUCKER.

A great portion of my time in May was devoted to the observation of Apple suckers, tests of insecticides, and the strengths necessary to render them fatal, and to taking account of the proportions of infested trusses on trees of different varieties before and after spraying. From none to 18 out of 20 trusses were found infested in the first instance, 3 to 8 out of 20 being more common proportions. The first spraying was on April 18, and other operations were carried out from time to time as the different varieties were ready—that is, when the blossom-buds were well separated, and about to expand. In some cases the proportion of infested trusses was greater after than before spraying, showing that hatching had gone on after the spraying. In the majority of cases, however, the proportion was reduced, in some greatly. It was impossible to tell, however, to what extent the reduction was due to spraying, as the earliest suckers were transformed to the nymph stage somewhat early in May, and began to migrate from the trusses to the foliage. By May 18 many perfect insects were formed, and these soon crept or flew away from the trusses.

The proportions of infestation given above relate to mature trees. They were much less on young trees, examples of from none to 2 infested trusses out of 20 being common. These were not sprayed. Somewhat more success in finding dead suckers than was mentioned a month ago attended the late sprayings; but still the proportion of dead to live ones was small. Much has been written about the necessity of force in spraying against suckers and aphides. In my opinion the quantity of wash applied to a tree is much more important than the degree of force. A coarse nozzle should be used, and the trees so well soused that the wash will run down inside the trusses of blossom-buds, to get to the axils of leaves and buds, where the suckers chiefly congregate. No degree of force with a small volume of wash will effect this object. Certain tests carried out with various washes, however, showed that many suckers wetted with a wash dropped out of the trusses when killed, or crept out to die, as a great number were found dead at the bottoms of boxes in which trusses taken off trees and wetted by dipping them into a wash were kept for 24 hours before being examined for results. Still, the results of spraying with a wash that killed nearly all the pests when trusses containing them were dipped into it were not satisfactory.

INSECTICIDES TRIED.

Being desirous of ascertaining the kinds and strengths of insecticides which might increase the penetrative power of soft soap, I tested carbolic acid, sulphuric acid, washing soda, ammonia, and methylated spirit alone and with soft soap. First it had been ascertained that the best soft soap, at the rate of only 6 lb. per 100 gallons of water, killed all the suckers well wetted by it. Out of twenty-seven suckers found after dipping infested trusses in this wash twenty-two were dead and only five alive, and three of the five were in a particularly compact truss. Of the other insecticides tried only ammonia and carbolic acid were found satisfactory. Sulphuric acid and washing soda proved to be very weak insecticides, as each failed when used alone, infested trusses being dipped, to kill any considerable proportion of the suckers, unless used at a

$\frac{3}{4}$ fluid ounce to a gallon of water proved fatal to nearly all the suckers in trusses dipped in it. With soft soap it was still more satisfactory.

In trials on labelled trusses sprayed well with a syringe the fatalities were less than when dipping was the method pursued, but carbolic acid or ammonia, with or without soft soap, gave good results.

IS DAMAGE BY SUCKERS EXAGGERATED?

My investigations dispose me to answer this question affirmatively. The presence of even minute creatures sucking the sap out of the trusses of blossom must impair their vigour. But does it do much if any more than help a truss to shed some of its superfluous fruitlets? Prolonged efforts to identify sucker damage have given negative results, and I am convinced that much of the damage attributed to suckers is due to other agencies. The complete withering of

weak trusses not infested, and afterwards to compare proportions of completely withered trusses.

After suckers reach the nymph stage it is supposed by some entomologists that they do no harm. But even if this be a certainty it is well worth while to spray against them, where they are numerous, after the blossom has fallen, when they are more exposed to being wetted than they have been earlier, in order to kill a large proportion of them before they reach the winged and egg-laying stage.

THE WITHERING OF APPLE BLOSSOM.

A little more needs to be said about whole trusses of Apple blossom withering instead of setting. Of course, this takes place more or less every season, and in trees of profuse blossoming especially. But the proportion of withering is much greater on some varieties than on others. In some cases it is no more than a salutary thinning of what would be excessive fruiting if all or nearly all the blossom set; but in others it amounts to half the trusses of blossom, and this is excessive. In the case of a piece of Worcester Pearmain on light land it is estimated at 75 per cent., and on another piece of the same variety it is put at 50 per cent. In each case the land has suffered severely from drought. Beauty of Bath on one piece of drought-stricken land, but not elsewhere, has failed to set more than half its blossom, while the failure, though less, is excessive on Lane's Prince Albert and Allington Pippin in one orchard, though not in another. Domino also has suffered, but chiefly in consequence of an attack of brown rot. *A Southern Grower.*

NEW OR NOTEWORTHY PLANTS.

BOMAREA BANKSII.

THIS, I believe, is the first record of a hybrid Bomarea. *B. Banksii* (see fig. 176) is a splendid plant, and I have pleasure in naming it after its raiser, Mr. G. H. Banks, foreman of the Cambridge plant-houses. The female parent was *B. Caldasiana*, one of the best of the Bomareas, profuse in flowers of yellow colour conspicuously spotted with brown; the male plant was the strikingly fine *B. patacensis*, which produces immense heads of scarlet flowers, and has been for several years a feature in the succulent house here. The hybrid is fairly intermediate in character; it has the red flowers and blue pollen of the male parent, but is conspicuously spotted in the way of *B. Caldasiana*, while in size the flowers are inclined to the larger *B. patacensis*. As a red brown-spotted Bomarea it is perfectly distinct. In habit and vegetative characters it can only be described as intermediate; the underground creeping rhizomes go further afield than those of the female parent, but do not travel so far as those of *B. patacensis*. The stems and leaves of *B. patacensis* are distinctly hairy. *B. Caldasiana* is glabrous, and the hybrid while certainly not glabrous does not approach the hairiness of its male progenitor. Whilst this is the first hybrid Bomarea to be placed on record, it is not the first that has been raised, for whilst at Colesborne, the well-known garden of Mr. H. J. Elwes, Mr. Banks raised a hybrid between *B. edulis* and *B. Caldasiana*. At Cambridge, too, he has raised the reverse cross between the parents of *B. Banksii*, and also a hybrid between *B. Caldasiana* and *B. hirtella*. I have myself been interested in trying to cross the nearly allied genera Bomarea and *Alstroemeria*, and a student gardener was set to work, with all the time necessary, but nothing came of the attempt.

It is unfortunate, but nevertheless true, that the right place has not generally been found in gardens for this fine genus, but the plants are very fine ornaments for the corridor and for large greenhouses. *B. Caldasiana* has displayed a number of its pendant, golden masses

FIG. 176.—BOMAREA BANKSII: FLOWERS RED.

strength which scorched the foliage and any open or half-open blossoms, while methylated spirit was not strong enough when used in any proportion which would not render it prohibitively costly.

Carbolic acid proved by far the strongest of the insecticides tried; but it is equally deadly to vegetation if not greatly diluted. Various trials proved that one fluid drachm of the crude acid to a gallon of water was fatal to suckers, and did not scorch foliage at all when sprayed on to it though it browned the leaves of trusses dipped into it. When trusses were dipped into it every sucker was found dead in twenty-four hours. Probably the pests were killed much sooner. This insecticide has been selected for mixing with lime sulphur when spraying against scab if any aphides are on the trees. For mixing with soft soap ammonia is preferred, as it seems to invigorate the foliage. The domestic cloudy ammonia was used, as no other was at hand, and

trusses is often attributed to sucker infestation, whereas it is much more commonly due to lack of pollination, brown rot, the maggot of the pith moth, or failure of nourishment due to drought, or some other cause. In not one of scores of withered trusses examined have I clearly traced the withering to sucker injury. In only a very small proportion of the withered trusses examined were any suckers or traces of their former presence found, while many trusses infested with suckers were seen to have set two or three substantial fruitlets. This is not conclusive evidence to show that none of the withering was caused by suckers, it must be admitted, because an attack which would only thin the fruitlets on a strong truss might destroy all on a weak one. My verdict, therefore, is not to be taken as "not guilty"; it is "not proven." To get a clear verdict next season it will be necessary to label a large number of weak (usually late blossoming) trusses infested with suckers, and an equal number of

in the Cambridge corridor for some time past; it is still fine, and in the succulent house *B. patacoccensis* has been magnificent. *Bomarias* are hardier than is generally supposed. *B. patacoccensis* has come safely through the past winter in a corner between the corridor and Palm house, and *B. Caldasiana* × *hirtella* against a west wall of the Palm house, after flowering last summer, has not been injured in the least during the past winter, and is now growing freely.

The accompanying illustration is from a photograph taken in the corridor of the Botanic Garden, Cambridge. The inflorescence is not a large one, and for this reason its character can be the better shown, but later inflorescences certainly will be very much larger. The flowers are $1\frac{3}{4}$ inch long and $\frac{3}{4}$ inch diameter at the mouth; outside they are scarlet, and inside they may be described as orange-scarlet. The numerous spots are brown. *R. Irwin Lynch.*

NOTES ON IRISES.

IRIS WATSONIANA.

THIS Californian Iris (see fig. 177), which was first described, though somewhat inadequately, by Mr. Carl Purdy, in *Erythraea*, V., p. 128, is there said to resemble *I. longipetala* Herbert in its growth, but to have flowers more like those of *I. Douglasiana* Herbert. Unless the present plant is something other than Purdy's species, it shows, to my mind, far more resemblance to *I. tenax* Douglas than to either *I. longipetala* or to *I. Douglasiana*. In some ways, indeed, its resemblance to a strong-growing form of *I. tenax* is striking, but it is distinguished by its slightly longer perianth tube, by the more sharply three-sided ovary, and by the fact that strong-growing specimens produce branching stems on which so many as eight or nine flowers develop in succession. In this respect and in its ovary, *I. Watsoniana* closely resembles *I. Douglasiana*, from which, however, it is easily distinguished by the shortness of the perianth tube, by its seeds, by its foliage, and by its divergent spathes, of which the two valves are usually attached an inch or more apart.

Its leaves are of a light and somewhat yellow-green, and grow to a length of about 28 inches by $\frac{3}{4}$ inch in breadth. The upper part droops so that the stems, which vary between 15 and 20 inches in length, are not hidden among the leaves, but show well above them. The foliage dies away almost entirely in winter, and is not persistent, like that of *I. Douglasiana*. The stems are either simple or branched, and are entirely clothed with narrow, reduced leaves. They are suffused with bright pinkish-purple at the base.

The spathes are almost identical with those of *I. tenax*. They are quite herbaceous, narrow, sharply keeled, one being usually set an inch or more below the other. The short pedicel of the first flower springs from the point of attachment of the upper spathe valve. In the later flowers the pedicel is often as much as $1\frac{1}{2}$ inch long. The ovary tapers slightly towards either end, and is neither so rounded as that of *I. tenax* nor so sharply triangular in section as that of *I. Douglasiana*. The perianth tube is short, $\frac{1}{4}$ to $\frac{1}{2}$ inch, but longer than that of typical *I. tenax*.

The flowers are relatively large, of some shade of violet or lavender-purple, usually with a curious suffusion of blue down the centre of both standards and falls. The latter extend almost horizontally and have on the posterior part of the blade a yellow or creamy-white patch veined with deep purple.

I. Watsoniana grows readily and is most floriferous in a well-worked warm, sandy soil. Together with other Californian Irises, it does not lend itself to transplantation, though this operation may be carefully carried out with some success immediately the flowers are over. Any disturbance in late autumn is almost certainly fatal to the plants. The best method of increase is therefore by seeds, which

germinate readily and give rise to large flowering plants in the second year after their germination.

IRIS DOUGLASIANA VAR. ALPHA.

THE seedling form of *Iris Douglasiana* Herbert known as Alpha (see fig. 178) has the sturdy, dark-green foliage of the type. The old leaves persist through the winter and then die away to a curious, almost brick-red colour in spring, when the new leaves are produced together with the flower stems. These are developed freely and reach a height of some 12 inches, standing almost erect in the centre of the plant. The leaves are 18 to 24 inches long and

leaves on the stems are suffused with pinkish-purple. It is possible that this is the result of some chance fertilisation with pollen of some other Californian species. The seed parent, at any rate, was *I. Douglasiana*.

The remarks on the cultivation of *I. Watsoniana* apply also to *I. Douglasiana*. *W. R. Dykes, Charterhouse, Godalming.*

NOTICES OF BOOKS.

THE BRITISH RUST FUNGI.*

OF the many groups of parasitic fungi which have been studied during the last three decades

FIG. 177.—IRIS WATSONIANA.

droop outwards, so that the flowers are not obscured.

The colour of the flowers is a creamy-white. On the blade of the falls near the end of the style branches there are a few deep crimson purple veins, between which the ground is suffused with faint yellow.

Two or three flowers are produced in succession from each spathe, so that the display lasts for a considerable time.

I can see nothing in the plant that is not typical of *I. Douglasiana*, which is so variable a species that, in my experience, no two plants produce flowers exactly alike, except, perhaps, in the fact that the spathes and the sheathing

none has attracted more attention or has been more fruitful of results than the family of the rusts, or Uredinales. As a consequence, we have gradually attained a knowledge of this group, which, though far from complete, is nevertheless considerably in advance of that of the majority of other fungi. Up to the present, however, the only complete systematic account of the native Uredinales was to be found in Plowright's classic treatise. Yet it is twenty years since that was written, and the additions to our knowledge during the interval have been many and important. There was much need,

* *The British Rust Fungi.* By W. B. Grove, M.A. Published by the Cambridge University Press. 11s. net.

accordingly, for a new conspectus of the family, and in the present volume this need has been adequately met.

The major portion of the text is devoted to a systematic account of the British species, some two hundred and fifty in number. In the author's words, "no attempt has been made to give a full synonymy," though sufficient reference has been given in each instance to enable the serious student to elucidate the origin and authority of the names employed. The descriptions themselves are satisfactory, and bear evidence of careful revision. Spore measurements are given in each instance, and text figures added in the majority of cases.

parasites, and no fewer than eighteen to those of the grasses.

The rest of the book—to be precise, the first 84 pages—is occupied with a general discussion of the whole family. In the first chapter an excellent departure from tradition is to be found, for here the author, instead of selecting *Puccinia graminis* as a type, for which it is peculiarly unfitted, outlines the life-history of the Nettle and Sedge rust, *Puccinia caricis*. By so doing he has avoided the dilemma of the writers of conventional text-books, who are invariably driven either to assign this all-important species to its two host-plants without comment or—more scientifically, if less clearly—to qualify

that this region of fruitful investigation was unexploited for a period of twenty years. What do we find?

Brefield (1889) came to the conclusion that the Uredinales were without any trace of sexuality—a point of view accepted by Van Tieghem and others. Schmitz (1880) and Rosen (1892) contributed fragmentary observations on the nuclear conditions, but in 1895 Poirault and Raciborski added materially to this information. In the following year Sapin-Trouffy, in a wide survey of the whole family, outlined the whole cycle of nuclear changes. According to his observations, a mature teleutospore is uninucleate, and gives rise to uninucleate sporidia. These sporidia give origin to a mycelium again with uninucleate cells. In the aecidia produced therefrom the nuclei become paired. As a result the aecidiospores are binucleate, and this condition is retained throughout (mycelia and uredospores) up to the reformation of the teleutospores, which, at first binucleate, become uninucleate by the fusion of the nuclei. This fusion Sapin-Trouffy regarded as a true sexual process. Since the appearance of this paper it was obvious to Blackman that "the critical point of investigation . . . is the early development of the aecidium," though for six years he was reluctantly compelled to leave the problem in suspense. That during that period no other grasped the significance of these facts is a signal tribute to Blackman's acumen, though at the same time it must be abundantly clear that the key to the solution was afforded by Sapin-Trouffy's memoir, and it is a matter for regret that our author makes no reference to this investigator, either in the text or the bibliography.

The later work of Blackman and Fraser, Christman, Olive, Hoffman and others is adequately dealt with.

The chapter of most general interest is that which outlines a number of the most characteristic life-histories, including what are probably the best known, the rust of Wheat and the Hollyhock rust. In the account of the former an interesting synopsis is given of the possible methods by which fresh epidemics are produced each year. Dismissing the Barberry as non-essential in the life-cycle, three possibilities are indicated—the wintering of the fungus, 1, by its uredospores; 2, by a permanent mycelium; 3, by Eriksson's mycoplasma.

The first possibility is shown to be entirely a matter of climate. The second has received definite support from the investigations of Pritchard, who found mycelium both in the grain and in the young seedlings. This discovery—of great practical importance—has since received further conformation, and may well prove the final solution. As regards the third possibility, our author starts with the diffident statement "it is difficult to come to any definite conclusion." He becomes more courageous, however, as he proceeds, and easily succeeds in quoting definite evidence against the conception. There is a sting in his concluding statement. "As Marshall Ward remarked, Eriksson merely inverts all the stages of a fungus attack on a cell, and supposes the last stage to be the first. This error and a misinterpretation of the microscopical appearances account for the whole wearisome persistence in an inherently improbable hypothesis."

Yet the author himself is not free from error as regards this species. For in the chapter on specialisation a reference is made to recent work on the breeding of immune varieties of Wheat. On page 225, in the specific account of *P. graminis*, we read that the only practicable remedy for this disease is to plant seed shown to be immune, and that "a certain progress has already been made by Biffen and others in the production of these." Now Biffen's work has not dealt with *P. graminis*, but with *P. glumarum*, the yellow rust, which is much the

FIG. 178.—IRIS DOUGLASIANA VAR. ALPHA: FLOWERS CREAMY-WHITE, WITH CRIMSON-PURPLE VEINS. (See p. 391).

It would have increased the usefulness of the text, however, if analytical keys of the various genera and species had been given with reference to the page on which each description occurs. This applies in particular to the larger genera. In the case of *Puccinia*, the species are arranged in the order of the families and genera on which they are parasitic—a simple and legitimate process. In the first section, which deals with the rusts parasitic on the Compositae, there are thirty-one species, occurring mainly on distinct and easily recognisable host-plants. A key would have enabled one to identify any particular specimen without delay. As it is, one may have to read through some fifteen pages before arriving at the species in question. Similarly there are nine pages to the Umbelliferous

their preliminary statement by a series of saving clauses.

A discussion on the sexuality of the Uredinales and the alternation of generations within the group follows. Here somewhat scant justice is done to the earlier investigators. After referring to De Bary's suggestion that "if there was any sexual act occurring in the life-cycle of the Uredinales, it would probably be found in connection with the aecidium," the author goes on to say:—"The first discovery was made by Blackman (1904), who found that, in laying the foundation of the spor-bed of the aecidium of *Phragmidium violaceum*, cells became binucleate by the passing into them of nucleus from an adjoining vegetative cell." Such a statement implies

commoner in this country. The only work dealing with the former species has been done in South Africa and India by Pole-Evens and Butler respectively.

This book, if we may use the phrase, is "of distinguished ancestry." It must take the place of a treatise of outstanding merit, and as such challenges comparison. If, then, we have been inclined to criticism, this must be our justification. Yet what we have urged is mainly a matter of detail, and in its essential features the book worthily fulfils the purpose of its author. *J. M. H.*

THE DISTRIBUTION OF PLANTS.*

The teaching of geography in schools has undergone many changes during the past few years, and its scope has been much enlarged.

Geographers realise nowadays that the vegetation of a country is limited on the one hand with its physical geography, and on the other with human geography and history—with archaeology.

These causes have doubtless contributed to the publication of the Oxford Geographies, of which the Editor, Professor Herbertson, contributes a short preface to Dr. Hardy's book.

Dr. Marcel Hardy is well known to plant-geographers and to ecologists as the author of an unusually interesting study of the vegetation of the Scottish Highlands, and of other works on plant geography.

There are difficulties in teaching plant-geography on a world basis in schools—difficulties proceeding from the same causes as is the case with geography proper when dealing with unknown regions, and to be overcome by the same means.

In two introductory chapters Dr. Hardy deals with general conceptions of vegetation.

This leads up to the idea of vegetation controlled and determined by physical surroundings. Part I. comprises the largest of the three sections of the book, and deals in a descriptive way with the main types of vegetation found all over the world.

The seven brief chapters which form Part II. deal comprehensively, if necessarily somewhat summarily, with the external conditions which are factors in plant growth:—Light, heat, water, wind, soil, etc.

Part III. is a "Survey of the Continents," or more strictly a survey of their vegetation.

It is this section of the book which will appeal most strongly to teachers, because—if we understand the preface aright—it is written to accompany a series of vegetation maps (Oxford wall maps), which have been prepared on the same projection and scale as those showing physical features and rainfall.

In general conception and arrangement of the subject-matter there is not much that is novel in the book, but its value for school and other work is much enhanced when its connection with those vegetation maps is clearly understood. Dr. Hardy is to be congratulated on the clearness with which he has treated a complicated subject in the limited space at his disposal, and we look forward with interest to the more advanced book which he promises on the same subject.

The present volume is profusely illustrated by photographs, drawings and maps, most of which serve their purpose adequately.

WEEDS: A FASCINATING STUDY.†

So many books are written on nature-study from the point of view of the botanist, and so many of them are open to criticism, that it is a special pleasure to read this little book by Mr. Praeger—the fourth of a series of Nature Study Manuals issued by the Cambridge University Press.

Many of these botanical nature-study books convey an impression of "snippets" of information, and there is so often a conscious striv-

ing after effect—a forcible attempt to demonstrate the interest of the facts.

Mr. Praeger has selected his text well, one which will have a practical interest for children in country schools—and most Irish schools are not far from the country!

In these chapters on "weeds" there are brought together many facts about plants and their life-histories which will provide subject-matter for botanical lessons—experimental and observational. There is the nucleus also of a knowledge of field botany, and, best of all and most rare, there is always the larger point of view.

noted in the plates, which are reproductions of some of Mr. Welch's fine photographs.

A detail which invites criticism from the botanist is the description and labelling of the fruits of the Dandelion, Thistle, Elm, etc., as seeds. *M. C. R.*

NOTES ON FRENCH HORTICULTURE.

CLEMATIS VERRIERIENSIS HORT. VILM.

AN interesting new hybrid Clematis (see fig. 179) bearing the above name was exhibited

FIG. 179.—CLEMATIS VERRIERIENSIS: FLOWERS ROSE COLOUR.

Thus, "Apart from their importance as agricultural pests, weeds are, as such, a fascinating study. The history of weeds is the history of agriculture. Ever since the people of the Stone Age first began to till the ground weeds and crops have gone hand in hand, and man's migratory movements, his work, and later on his trade, have all played their part in assisting the spread of his enemies, the weeds."

It is an interesting departure in a book intended for school work, especially in Ireland, to find the common names of the plants rendered into Erse, and another Irish feature is to be

by Messrs. Vilmorin, Andrieux, at the May exhibition of the French National Society of Horticulture.

It is the offspring of a cross between *C. chrysocoma* and *C. montana rubens*. The female parent, *C. chrysocoma*, is a native of Yunnan, introduced into cultivation by M. Maurice de Vilmorin, and figured in the *Botanical Magazine*, tab. 8,395. The male parent, *C. montana rubens*, now well known, comes from Western Hupeli, and was collected by Mr. Wilson, and brought into cultivation by Messrs. Veitch. The new hybrid has the vegetative

* *Introduction to Plant Geography.* By M. E. Hardy, D.Sc. (The Oxford Geographies, edited by A. S. Herbertson.) (Clarendon Press, Oxford, 1913. Price 2s. 6d.)

† *Weeds.* By R. Lloyd Praeger. (The Cambridge Nature Study Series, edited by Hugh Richardson, M.A.) Price 2s. 6d.

characters and vigour of *C. montana rubens*; the flowers are of a good, delicate rose-colour, with sepals larger than in *C. m. rubens*. For the most part the characters of the flowers and leaves are intermediate between those of the parents. The hybrid was raised by Messrs. Vilmorin at Verrières le Buisson—hence the specific name.

PEACH BEARING ALMOND BRANCHES.

THE Scientific Committee of the National Society of Horticulture at its meeting in April had before it an exhibit by M. Aubin of shoots of Almond with young fruits taken from the remarkable tree belonging to M. Fromont, of Montreuil. This tree—a Peach—has borne each year since 1908 branches identical with those of the Almond. A second Peach tree growing near, and of the same variety, shows the same phenomenon. These "graft-hybrids" were the subject of a note to the Academy of Science (1911), written by the late Professor Griffon. The two trees are espaliers, and are grafted on the Almond. They are about sixty to eighty years old, and belong to a seminal variety closely resembling "Grosse Mignonne."

The Almond-like branches bear large white flowers, which contrast markedly with the smaller pink flowers borne on the other branches of the trees. The fruits are like young, elongated Almonds, but so far they have always fallen when they have reached a length of about three-quarters of an inch.

The most probable explanation of the phenomenon is that applied by Winkler and Baur to the graft hybrids of the *Cytisus Adami* type. According to this hypothesis, which is described fully in an illustrated article in this journal (*Gardeners' Chronicle*, Vol. L., third series, p. 161), a fusion of tissues of stock and scion arose after the grafting of the Peach on the Almond. In the case under consideration it is probable that in the Almond-like branches the superficial layer is that of the Peach, and the deeper layers are derived from the Almond; hence the absence of colour in the flowers. Microscopical examination of the tissues would probably determine this point.

CHEIRANTHESIMUM CAYEUXII.

ANOTHER interesting exhibit at the May exhibition already referred to was the second generation of *Cheiranthesium Cayeuxii*, the hybrid, raised by Messrs. Cayeux and Le Clerc, between *Erysimum Marshallii*, Hort. (syn. *E. Allionii*, Hort.) ♀ and *Cheiranthus mutabilis* ♂. The female parent, *E. Marshallii*, is itself a hybrid raised by John Marshall, of Limburn, by crossing *E. Perofskianum* Fisch. et Mey. and *E. ochroleucum* D.C. It is figured in the *Floricultural Cabinet* by Harisson (1850, p. 265), and referred to by M. Bois in a recent article in *Revue Horticole* (1913, p. 443). The plants of the first generation of the cross made by Messrs. Cayeux and Le Clerc showed a certain amount of variation—from copper-red to yellow-orange—in the colour of their flowers.

In the second generation the colour-variation is far greater, so great indeed that it is possible to classify the colours into six groups:—Pale yellow, bright yellow orange—of darker tint than in *E. Allionii*—yellow passing to violet, copper-red orange, yellow striped on reddish-violet ground.

Many of the plants have inherited the character of *C. mutabilis*, and bear flowers which open pale and become more and more violet with increasing age.

Among the series are some new colours of considerable interest from a horticultural point of view. *A. Meunissier*.

A CANADIAN GARDEN.

NOTWITHSTANDING the rigours of the Canadian climate, Toronto, the Queen of Canadian cities, has many lovely gardens, and among these gardens those at Craleigh—the residence of Sir Edmund Osler—are supreme in the perfection of their greenhouse flowers. From autumn until spring the houses are brilliant with colour. Among the subjects which are cultivated with such success are Chrysanthemums of the best varieties, *Schizanthus*, *Cineraria*, followed by *Calceolarias* and *Gloxinias*. The *Calceolarias* grown at Craleigh are equal to those grown for exhibition purposes in England, which is surely a test of cultural skill. For the first time probably in any Canadian garden those charming little *Narcissi*, known as *minimus* and *cyclamineus*, have been grown in pots, and they proved a useful aid to the scheme of colour at that season. It is a great joy when the first Darwin Tulips blossom after months of ice and snow—a joy which those who have never visited

from the glare of the summer sun. It is gratifying to find that in England so much interest is taken in the subject of Canadian horticulture; Mr. Allen the head gardener at Craleigh, to whose skill are due the admirable results achieved at Craleigh, is a native of Ireland. *E. T. Cook.*

EDUCATIONAL GARDENING.

SCHOOL GARDENING AND PUPILS' GARDEN PLOTS.

IN Germany and Switzerland, so long as a hundred or more years ago, many children, of the poorer classes in particular, were systematically instructed in garden cultivation, partly perhaps at the instigation of the famous teacher Salzmann, who in 1801 made an appeal on behalf of the systematic "employment of poor, abandoned children in agriculture and gardening." In his treatise, *Gartenbau für Knaben* (1910), Herr

FIG. 180.—CRAIGLEIGH, TORONTO, CANADA.

this country can scarcely appreciate. At the same time as these early Tulips we also have sweet-scented Hyacinths, and the flower gardens seem once more alive as the Easter festival approaches.

It can easily be imagined how much appreciated the indoor gardens are in Canada, for otherwise not a flower would be seen during the winter months.

Last year complete success was attained with Grape vines, those grown being favourite varieties in England—Black Hamburg, Muscat of Alexandria, Foster's Seedling, and Madresfield Court. These particular vines were among the first of their kind to be grown here, but the bunches of the last-named did not show a single cracked berry, and were faultless in colour and shape. An equally gratifying result is expected in the case of the fruit trees in pots also being cultivated for the first time.

During the summer the out-door garden is full of interest, from the time of the Daffodil and Tulip until the frosts. The lawns are a source of great joy—wide expanses of emerald-green grass, which provide refreshing relief

Peter Schmidt calls attention to an all-but-forgotten three-volume work that appeared from 1836 to 1847, *Feldgärtnerkolonie für Armenkinder*, by Deacon Lange. In it there is to be found a detailed description of the "special educational establishment for gardening and husbandry for boys," connected in 1821 with the charity school of Halle. At the same time gardening for boys was systematically promoted by the "work schools" instituted on the Holstein estates of Duke Peter of Oldenburg. At the "industrial schools" maintained in 420 different places in 1841 (508 in 1843) by the "Charitable Society of the Kingdom of Württemberg," 11,000 boys and girls received instruction in gardening and fruit-growing. The practice, however, has long been dropped. A private institution for "boys' work" founded in 1828 and still existing at Darmstadt makes gardening the chief subject of instruction. Attendance numbered 6 in 1828, 144 in 1860, and 368 in 1880; further increase was impossible as finances would not allow of an enlargement of the institute. After a few years it was taken over by the town autho-

rities and has since continued to grow and flourish. Lately the concourse of pupils has so increased that in 1908 the deficit amounted to almost 3,600 marks. Very minute and interesting information about this model school is to be found in Herr Schmidt's treatise.

These old attempts may be considered as the precursors of the present school-gardening movement started about a decade ago, the results of which must already be recognised as valuable. It is a movement for the establishment of serviceable gardens in connection with secondary, elementary and village schools for the theoretical and practical teaching of gardening, together with individual practice, as well as recreation for mind and body.

It is, of course, difficult to provide gardens for

The latter principle is already generally adhered to in the "school children's gardens," which are not cultivated by all or many children in co-operation, but each bed by one scholar alone. The first attempt of this kind originated in England with Mr. Rooper, the Southampton school inspector. Fifteen years ago he formed the project through small gardening "to awake a love for nature in the children, to interest them in gardening and to tender them a pleasant, healthy and profitable occupation for their leisure hours." He fenced in a piece of not very fertile arable land in the neighbourhood of Bournemouth and divided it into twelve large beds, which were given to as many school boys for cultivation. This experiment was a great success.

them to the next lesson, worked up into an account of the day's doings.

Each of the twelve big beds is divided into fifteen rows, and each boy must plant his fifteen rows with the same vegetables. This is to induce a kind of competition among the lads, to urge them to diligent work and to arouse their ambition. The fifteen rows contain the most common vegetables, Potatoes, different kinds of salads, Tomatoes and Spanish Onions. Each boy may sell the produce of his bed. The sum is handed over to the teacher, who keeps an exact account of each boy's takings. The pupils must also keep accounts. At the end of the year the memorandums are compared and each boy receives one half of his takings, while the other half goes to cover the cost of the seeds and other expenses.

FIG. 181.—CONSERVATORY AT CRAIGLEIGH, TORONTO, CANADA.

schools in the centres of large and crowded towns, but they can easily be provided in suburbs, small towns and villages. In England and Germany the establishment of school gardens has made some progress; it has made more in Belgium, France, Scandinavia, Austria and Switzerland. According to Herr Johann Jordi, the chief object of school gardens is to stimulate the scholars to imitate the school gardens in miniature at home. The teacher should not, therefore, grudge the trouble of occasionally undertaking the supervision of his pupils' gardens. To sustain the interest of the school children in the school garden Herr Gienapp advises, "as a valuable educational momentum, that the product of their joint work should be left to the children themselves in the first place," whether as prizes or at a very low price.

At the entrance to the garden there is a shed containing a large writing-desk and twelve complete sets of gardening implements, to each of which belong a Dutch axe, a spade, rake, dung-fork and shovel. Wheel-barrow, watering-pots, baskets, brooms and bast are common property. Each of the twelve beds in the garden bears the same number as the implements belonging to it. The twelve boys are each under the obligation to keep the tools clean. On three afternoons in the week lectures on gardening are given and each boy must attend a twelvemonth's course. After every practical lesson, given by a gardener appointed for the purpose, there follows a lecture. The gardener explains to the pupils why this and that had been done outside, answers any questions that may be put, and takes care that the boys make notes, which they must bring with

In addition to the twelve numbered beds are other three experimental and early beds. Delicate plants such as Asparagus, Cucumbers and Marrows are planted here, and the needful sowing done in the spring for the planting out into the "personal" beds.

At the east end of the garden are the fruit and flower beds. They contain chiefly Strawberries, Bilberries, Gooseberries, Currants, Raspberries, Plums, Apples, Pears, Roses, Mignonette and Pansies. The boys learn to graft and cultivate fruit trees and Roses. A Mushroom bed has also been prepared for them.

Mr. Rooper's experiment has met with success, as we have already said, and to the joy of their parents the boys have long exercised their skill also at home in their cottage gardens. The objection made that the boys' school work

would be neglected through this occupation has not proved true; on the contrary, they work more diligently than ever, for fear they should be forbidden to touch their beds if their school duties are not wholly and well fulfilled. *Leo-gold Katscher.*

AMERICAN NOTES.

ANTIRRHINUMS FOR CULTURE UNDER GLASS.

OF late years Antirrhinums have come greatly to the fore in the United States for greenhouse culture, and are now procurable in quantity in the large flower markets from early October until the end of June. Owing to the fact that our summers are very hot, and that winds are common, Snapdragons cannot be very successfully cultivated here except near the seaboard and at some of our mountain resorts, but under glass spikes of magnificent quality are produced which bring very good prices in the flower markets. The most popular colour is pink; following this in favour come yellow and white. The darker shades are little favoured.

Whilst very good Antirrhinums can be grown in pots, the usual method of culture is in benches or beds. For mid-winter blooming cuttings should be rooted in April or May, or seed can be sown some time in May. Seedlings are first transplanted into boxes, later placed singly in 2½-inch pots, and from these shifted into 4-inch pots. About the last of August the plants are set out in benches 12 by 10 inches apart; some growers set them even closer. I have found 4 inches of soil ample for a winter crop. The bench becomes well matted with roots before winter sets in, and soon dies out between waterings; feeding with sheep manure, fine bone or Clay's Fertiliser is used after January, and as the weather warms up in spring a mulch of well-rotted cow manure proves beneficial.

From plants set out late in August we commenced cutting spikes early in October, and have had plenty of flowers from that time on. At the present—May 7—our bench is a veritable thicket of spikes, many of them 24 to 30 inches long from the first flowers to the top of the spikes; 24 inches of open flowers is not at all unusual. Antirrhinums, as is well known, keep splendid in water, and grown in blocks of distinct shades are one of our finest of all winter flowers. I was pleased to note that an American Snapdragon secured an Award of Merit on April 21 before the R.H.S. in London. The particular variety, *Nelrose*, showed by Mr. W. Wells, is one of the most beautiful varieties I have ever seen, and should prove very popular both with private gardeners and florists. It is perpetual flowering and bears rose-pink or lilac-tose coloured blooms on stems three feet in length.

A night temperature of 45°-48° in winter suits Snapdragons. They also want plenty of fresh air. In a higher temperature they are not nearly so good. Plants when cut down soon start from near the ground again, and in some cases they throw so many shoots that a little judicious thinning is necessary. Anyone who does not want to try named varieties will do well to try the best strains on the market, for the separate colours come very true from seed. The intermediate strain I find the best for greenhouse culture. In fumigating Snapdragons I would warn growers never to use hydrocyanic acid gas. It does not scorch the foliage, but all the tops hang limp after a light fumigation. I am sure that if some of the big trade growers in Britain will take up Snapdragons and grow them in the same way as our American Carnations, only somewhat cooler, they will find them very profitable. *William N. Craig, Brookline, Mass., U.S.A.*

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. COOKSON, Oakwood, Wylam-on-Tyne.

REGULATING THE HOUSES.—The weather in May was of an unusual character. During the first three weeks it was dry in the daytime, with frost at night on several occasions. The third week was very dry and warm until the last day or two, when 6° to 8° of frost were registered at night. In these circumstances it has been a difficult matter to regulate the houses, and at a time, too, when many of the plants were at their most tender stage. The cultivator has had to guard against the least excess of moisture in the atmosphere and sudden fluctuation in the temperature or a continuance of low temperatures. But a close examination of the outside thermometer between the hours of 7 and 9 p.m. will show whether at such times extra fire heat will be required or, what is of more importance, if it is necessary to reduce the amount of atmospheric moisture to prevent the new growths being damaged by spotting and other causes. The damping of the houses should be done sufficiently early in the day, so that there will be no danger of moisture condensing on the plants when the cooler evening temperatures are reached. It is essential to have a liberal amount of heat in the hot-water pipes at all seasons before admitting the cool evening air. See that cold draughts do not reach the plants. If the lower ventilators on the leeward side of the house are brought into use there will be less danger from cool draughts, and this is why the ventilators, and especially those used at night, should be situated at or a little above the level of the hot-water pipes, for then the air becomes warmed a little. In the cooler divisions the roof ventilators are rarely used unless the conditions outside are moist and favourable. But the lower ventilators on the leeward side are used freely at night when the conditions are favourable. I find it very beneficial during periods of dry warm weather to run the hose-pipe through a ventilator and damp the outside walls and ground about the *Odontoglossum* houses thoroughly. This is done in the evening, and results in a refreshing atmosphere inside the houses.

INSECT PESTS must be carefully kept in check, and constant observation is necessary to discover any pests and destroy them before they cause serious damage. *Cyrbidiums*, *Sobralias*, *Lycastes* and certain other Orchids soon become infested with red spider when grown in a dry atmosphere. Sponging the plants with clear water and keeping the leaves well syringed is the best method to keep these pests in check. Vaporising and spraying with some safe insecticide at least once a fortnight is the safest method of keeping down thrips and other pests that attack Orchids.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

STEPPING STONE PATHS.—Many of the early dwarf flowering plants are over, but varieties raised from seed in small pots should now be ready for transplanting. Many will flourish in the natural soil during the summer months, and amongst these are *Alyssum*, *Aethionema grandiflorum*, *Androsace*, many of the *Campulula* family, the Australian cress and *Ionopsis aculea*.

HERBACEOUS BORDERS.—All hardy perennials are now making rapid growth, and require daily attention in the matter of staking, watering and thinning. In the early stages a considerable amount of thinning is required, and the strong, robust varieties should stand from 12 to 18 inches apart, to ensure the growth of fine flowers and to prevent the plants from straggling after rain and wind. It is prefer-

able to avoid as much as possible tying the plants, but while they are quite small push firmly into the ground some untrimmed Pea sticks, the tops inclining outwards, the height of the sticks depending upon the height of the plant. The young growths and foliage soon hide these supports.

THE WATER-SIDE GARDEN.—Notwithstanding some sharp frost, Primulas are very gay, especially *P. japonica*, *P. pulverulenta*, *P. Poissonii*, *P. Bulleyana* and *P. capitata*. Plant these species in masses on the margins of water in soil which is not water-logged, but which has plenty of moisture in the lower strata, to which the plants can help themselves at all times. Other flowers to follow these, under similar treatment, are *Iris Kaempferi*, *I. Momieri*, *I. ochroleuca* and *I. gigantea*; *Spiraea Aruncus*, *S. filipendula*, *S. Ulmaria splendens*, *S. Lindleyana*, *S. venusta* and *S. gigantea*; *Senecio clivorum*, *S. Veitchii* and *S. tanguticus*; for foliage, *Rodgersia podophylla*, *Glyceria spectabilis* and *Saxifraga peltata* should be grown.

CLIMBING PLANTS.—Train the rapidly-made shoots at short intervals, never allowing the growths to intertwine. Especial care should be taken with Clematises. Nelly Moser Clematis is a charming climber, continuously in flower on tree stumps. *Solanum jasminoides* and *S. crispum* in a south, sunny aspect require constant attention.

ROSES—Syringe with Quassia extract on the first appearance of aphids. One gallon is required for 100 gallons of water. It is economical to use this as a preventive.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

FRAMES.—Now that the weather is warmer and most of the summer bedding plants are outside, the frames can be used to protect the young plants for autumn and winter flowering. If the number of heated frames is limited, the more tender subjects should be selected for such protection, and a little heat applied at night if necessary. Cyclamen may now be re-potted, the stronger plants into pots of 5-inch or 6-inch size, the weaker and smaller into those of 3½-inch to 4-inch size. The pots should be placed on a bed of ashes, after being lightly dusted with soot. Shade the plants from strong sunshine, and damp the space between the pots at about 2 p.m., just before closing the frame. When the plants become established in the flowering pots, the lights can be removed on mild nights, and replaced before the sun becomes too strong the following morning. If thrips are troublesome, fumigation should be resorted to. *Celosias*, *Cockscombs*, and tuberous-rooted *Begonias* will do best in a heated frame. They should be re-potted as required, and all flowers removed from the young *Begonias* until they are established in their final pots. *Salvias*, *Torenia*, *Heliotropes*, *Balsams* and *Browallia* species can be placed in unheated pits or frames. Arrange the staging so that the plants may be close to the roof-glass. Close the frames early and make as much use as possible of the heat of the sun. The plants should be re-potted before they become pot-bound. If the least trace of green-fly should make its appearance, spray with a solution of Quassia. The young stock of the berry-bearing species of *Solanums* should be re-potted and placed in a cold frame. They should be syringed daily, and watched carefully for aphids. When the plants flower the syringing should be discontinued, and when the fruit is set an application of liquid manure twice weekly will be beneficial. Year-old plants which have again started into growth may be plunged out-of-doors, or in a frame containing a spent hot-bed. Pinch out the points at the end of June, and then allow the natural growth to continue. The plants will be housed early in September. Cuttings of *Euphorbia pulcherrima* and *jacquinaeflora* may be inserted singly in thumb-pots, the pots being afterwards plunged in bottom heat with a temperature of 75°. They should be kept closely shaded until rooted,

and the cuttings will benefit by being sprayed morning and evening. They should be gradually inured to light and air, and finally placed on a shelf close to the roof-glass. As the cuttings of *Begonia Gloire de Lorraine* become rooted they should be transferred into 3-inch pots, which can be placed on a bed of ashes or a staging covered with ashes or coco-nut fibre. The temperature of the house should be about 65°, and the plants will benefit by being syringed and by a damping of the floors and spaces two or three times a day. Shade the plants and remove all flowers. The spaces between the pots should be dusted with soot and the plants fumigated about once a fortnight. Cuttings may still be struck for flowering in small pots.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

PINES.—In a short time fires can be discontinued, except during cold and unfavourable weather. If the bed is situated over hot-water pipes, the hot water may be made to circulate on hot, sunny days through the beds only, thereby utilising what would otherwise be unserviceable on such occasions. On fine mornings stop the fire early, and never use more fire-heat than is absolutely required. Maintain the temperature and continue the general treatment to fruiting plants as formerly directed. The fruit which developed during last February will be fast approaching maturity. Attend to all the requirements of the plants regularly, and especially in the matter of watering, for neglect in this respect will prove very detrimental. Afford water much more sparingly as the fruit commences to colour. Remove all suckers, as advised previously, excepting the one for stock, and avoid, if possible, the retention of a sucker at the base of the fruit stem, as it will tend to push aside the fruit. Cease overhead syringings, and maintain the requisite atmospheric moisture by damping the paths and staging frequently.

PEACHES AND NECTARINES.—To ensure highly-coloured and richly-flavoured fruit, admit an abundance of air on all favourable occasions, and fully expose the fruit to the influence of the sun and light by drawing aside—not removing—any leaves close to the fruit and those intercepting the direct rays of the sunlight. Lessen the application of water at the roots gradually, but do not allow the soil to become excessively dry. As the fruit ripens, discontinue overhead syringings, but continue to damp the floors and the surface of the inside border. Fire heat is only necessary to maintain a temperature of about 60°, concurrent with a free amount of ventilation. Peaches and Nectarines will benefit from this course of treatment, and the more slowly the fruit ripens the richer will be the flavour and the higher the colour.

STRAWBERRIES.—Whilst the fruit is swelling, afford copious waterings to late varieties, such as *Waterloo*, growing in frames or pits. Applications of liquid manure will also aid in the securing of good-sized berries. Avoid currents of dry air, and maintain the requisite atmospheric moisture by spraying the plants both morning and afternoon. Cease the application of liquid manure directly the fruit commences to ripen, giving sufficient water only to prevent the foliage from flagging.

CHERRIES.—To prevent the fruit cracking, it must be kept free from moisture overhead. Maintain a genial atmosphere by sprinkling the paths and borders with clear water, and allowing the air to circulate freely both by day and night. If necessary, use the hot-water system. Exclude all birds by placing small-meshed netting over the ventilators.

CUCUMBERS.—To grow Cucumbers successfully a steady bottom heat and a warm, moist atmosphere are required. Syringe the walls and paths of the house several times daily and add a little liquid manure to the water, which will benefit the plants and keep insect pests in check. Fumigate the house immediately should these

later appear. Remove all discoloured leaves, which encourage red spider and thrips. To ensure a regular supply of Cucumbers, raise fresh plants by sowing seed at intervals.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

APRICOTS.—All Apricot trees should now be finally thinned. Recently transplanted trees, though apparently as strong as older trees, should not be allowed to carry as much fruit as the latter. Keep the soil well watered, for all Nectarine trees, and especially those on walls, require large quantities of water when in active growth. Manure water used at intervals will assist the fruit to swell. Pinch the shoots not required for extension and secure all others to the wall.

WATERING OF FRUIT-TREES.—Should the present drought continue, the watering of fruit trees must have careful attention; indeed, this is essential to prevent the fruit dropping from wall trees of Cherry, Plum, Peach and Nectarine. Give copious waterings. During hot weather syringe the foliage in the late afternoon. Place a mulch of rotten manure around the base of tree, removing same before watering, and replacing afterwards. Never apply artificial manures or manure water to the roots when the soil is dry, but first afford a good watering.

PLUMS.—Regular attention should now be given to these trees. Fasten to the wall or wires all shoots required for extension or for filling up gaps; pinch the remainder at the fourth or fifth leaf. Allow the weaker shoots to grow for the present: these may be stopped later if necessary. These smaller shoots when well ripened usually fruit well. Guard against aphid attacking the tender growths; this pest seems to spread most rapidly during times of east winds, when the atmosphere is dry. Fruits of dessert varieties should be thinned to a reasonable crop; but it must be remembered that many Plums drop at the stoning stage, and this must be taken into consideration. Another cause of Plums and other stone fruits dropping is drought at the roots: therefore see that the roots receive copious waterings. In addition to all this, a mulch may be spread over the soil as recommended above. Young trees need careful training. It is now that the foundation of the tree will be laid, for these shoots will, in time, constitute the main branches of the tree. Remove extra vigorous shoots, as these might grow so vigorously as to make the tree irregular in shape. No stimulants need be applied to the roots, as young trees always grow freely in good soil, and coarse growth is not desirable.

STRAWBERRIES.—The soil in most places is very dry, and Strawberries will fail to give good returns unless they are watered. The early varieties will be benefited by applications of liquid manure, but this will not be necessary if concentrated fertilisers were applied earlier in the season. Manure should not be applied after the berries commence to colour. In order to obtain very early fruits, thin the trusses on some of the plants with a view of throwing all the energies of the roots into the berries that remain.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, Tynninghame, East Lothian.

LETTUCES.—This is a difficult crop to maintain, and the only way to be sure of a steady supply is to sow a few seeds at intervals of ten days or a fortnight. Transplant while the plants are still small, leaving enough seedlings in the lines to fill up. Lettuces grow best in a friable soil, well enriched, and, unlike a large number of vegetables, succeed best when the soil is not very firm. In gathering do not cut, but twist the whole plant round till the tap root comes away.

LEEKS.—The more forward seedlings will very soon be large enough to transplant. The old-fashioned practice of drawing drills or furrows at 15 to 18 inches apart, and setting the

leeks deep in these cannot be excelled. In dry weather and dry soil it may be necessary to flood the drills with water some time before planting, an essential part of the operation being the forming of deep holes into which to drop the plants. These should be sorted at lifting, and the roots thickly-coated with prepared mud, so that when each is dropped into its hole and watered it may be able to continue growing without further attention. The plants should be arranged so that the leaves when larger will bend over into the furrows.

PEAS.—The second crop will now be well in bloom, and overtopping its supports. Cut off the tops with a hook, to induce freer lateral growth, and an earlier production of pilled pods. If an abundant supply of manure-water can be afforded, it will be of very great benefit. Those who are producing Peas for exhibition must allow the haulm plenty of space. Examine the pods to make sure that those left are full. Thin the pods and laterals to give those left every advantage. Blood-manure has a beneficial effect on the colouring and texture of the pods. If not already done, the second last sowing of late varieties should be put in without delay.

CELERY.—Nothing is gained by allowing this crop to stand too long in beds before final transplantation, large plants being difficult to separate without loss of roots. The trenches having been prepared some time ago, a slight dressing of old Mushroom dung and pigeon manure should be applied. If weeds are in evidence they can be lightly forked into the ground. Set the plants 1½ to 2 inches below the surface, and leave a slight depression to receive water when it is necessary to apply it. In light, free soil, make the soil firm by trampling after the planting is finished. At this time of year, either plant in dull, sunless day; or, if sunny, defer planting until well on in the afternoon. Early celery will benefit by a thin addition of soil mixed with manure spread evenly among the plants; if dry, the ground should be previously soaked with water. Weeds springing up on the sides of the trenches should be destroyed.

VEGETABLES.

CAULIFLOWER MAGNUM BONUM.—During the past three weeks we have been cutting splendid little heads of this variety grown in 8-inch pots. The seed was sown during the middle of September, pricked out into cold frames, potted up at the end of November, and grown on in a cool house. During the last six weeks the plants have been placed in sheltered positions, where they have yielded a splendid return. This year there is a wealth of Broccoli of good quality, but not to be compared with the delicacy of the Cauliflower.

KALE LABRADOR.—This is a delicious vegetable and distinct from any Kale known to me. It is by far the best flavoured, the hardest, latest, and most prolific during the months of April and May. Nearly thirty years ago a lady gave me some seed which she brought direct from Labrador. So well has it been thought of here that we have grown it every year since. This variety is often confused with *Asparagus Kale*, which is absolutely distinct, and very inferior.

CABBAGE.—The Cabbage is a favourite vegetable, especially so in early spring. It has been greatly improved during the past half century. Formerly it was considered that to have cabbages fit to eat by Whitsun was very satisfactory; but nowadays Cabbages of the highest quality may be cut from February onwards. Some cases of failure have come under my notice lately, but experience teaches me that this is due to two main causes, viz., bad stocks, and sowing the seed too early. Three varieties that do especially well here are *Sutton's April*, *Ellam's Early*, and *Flower of Spring*. Out of 1,200 plants of the first-named in one bed only one has been found to fail. The remainder have either been cut or are ready to cut at the time of writing. *E. Beckett, Aldnam House Gardens, Elstree.*

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.
Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JUNE 8—

United Hort. Ben. and Prov. Soc. Com. meet.

WEDNESDAY, JUNE 10—

Birmingham Bot. and Hort. Soc. Orchid Sh. (provisional).

SATURDAY, JUNE 13—

Stirling Hort. Assoc. outing to Greenfield, Alloa. R.H.S. Gardens Club outing.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 58.2°.

ACTUAL TEMPERATURES:—

LONDON, *Wednesday*, June 3 (6 p.m.): Max. 68°; Min. 48°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, June 4 (10 a.m.): Bar. 29.9; Temp. 67°. Weather—Bright Sunshine.

PROVINCES, *Wednesday*, June 3: Max. 69°, Bath; Min. 39°, Buxton.

SALES FOR THE ENSUING WEEK.

TUESDAY—

Japanese Dwarf Trees. At Stevens's Auction Rooms, King Street, Covent Garden.

SATURDAY NEXT—

Freehold Market Garden, 19 acres, with modern buildings, stabling, etc. To be offered by Auction on the Estate, Penton Hook, Staines, at 4 o'clock, by Protheroe and Morris.

Fumigating with Hydrocyanic Acid.

The correspondence which has appeared recently in these pages indicates that a diversity of opinion exists as to the value and best mode of application of hydrogen cyanide for the purposes of fumigation. We give, therefore, the results of prolonged tests carried out by M. Paul Marchal, Professor of the National Agricultural Institute of France, and published in the *Vie Agricole*. Inasmuch as the correspondence referred to above showed that some uncertainty exists as to the strength of the ingredients for producing hydrocyanic acid gas, we will deal first with that aspect of the subject. The cyanide of potassium should be practically pure—guaranteed of not less than 98.99 per cent. purity. It should be in the form of small white pieces, and should be weighed out into amounts determined, as indicated below, by the volume of the structure to be fumigated. Each lot should be wrapped in stout paper, and the packets should be kept in a glass-stoppered bottle labelled "Poison." The sulphuric acid employed for generating the gas should be commercial sulphuric acid of

specific gravity 66 Beaumé. It is important that the sulphuric acid should be free from nitric acid, as an impurity in the latter substance is apt to cause burning of foliage.

The proportions by weight in grams in which the ingredients should be used are: Cyanide of potassium 1, sulphuric acid 1½, water 3. When everything is ready the right amount of water should be placed in a glass or glazed porcelain vessel so large that when the acid and cyanide are added it is not more than half full, for the reaction producing the cyanide is apt to cause effervescence, and a vessel deep enough to prevent splashing is therefore to be employed. To mix the ingredients first add the water—for if water be added to the acid rapid boiling is caused, and if the acid be splashed on hands or clothes burns result.

Directly after the acid has been added the packet of cyanide, held at arm's length, should be placed in the vessel, and the operator should leave the house at once, closing the door tightly as he goes out. The more thoroughly the house is closed the more efficacious is the treatment. Hence wherever possible cracks should be sealed and, of course, all ventilators must be closed. Arrangements should be made also for opening ventilators from outside. The operation should be carried out at night, for hydrocyanic acid in the presence of light has an injurious effect on vegetation.

The time of fumigation should be, for plants in activity 40-45 minutes, for plants in a resting stage one hour.

The amount of cyanide of potassium to use is 10 grams per cubic metre. In point of fact, twice that quantity has been used, and the time of exposure extended to two or even three hours without ill-effects to vegetation. Nevertheless, the quantities which should be used in first tests are: For every cubic metre of space 10 grams of cyanide of potassium, 15 grams of sulphuric acid, and 30 grams of water. If the house to be fumigated is of considerable size several glass or glazed porcelain vessels may be used, and the total quantity of the several ingredients divided up between them, always, of course, in such a way that each vessel receives the cyanide, acid and water in the proportions of 1, 1½, and 3. If this latter course be adopted the operator first adds water and then acid to the vessels, and then, starting at the vessel furthest from the exit, he places the potassium cyanide in it, walks quickly to the next, and so on, and when he has added the cyanide to each vessel he makes without delay for the door.

Translated into English measures the above quantities read: For every 100 cubic feet of space in the house use (*in avoirdupois measure*) 1 oz. of potassium cyanide, 1½ oz. sulphuric acid, and 3 oz. of water.

It will be of considerable interest if those gardeners who carry out fumigation with these proportions of materials will keep careful note of the results, and will communicate them to the Editors.

Supplementary Illustration.—*Philesia buxifolia* is found wild in South America from Chili to the Straits of Magellan. It forms a shrub about 3 or 4 feet high, and bears pendulous, red flowers. *Philesia* is closely allied to *Lapageria*, and a hybrid named *Philageria Veitchii* was raised between the two plants by Messrs. James Veitch and Sons in 1872 (see fig. 182). At that time bigeneric hybrids were rare, and the fact of these plants hybridising appeared to some at the time to be proof that the parents belonged not to two but to one genus. *Philesia buxifolia* is said to be remarkably strong in withstanding the effects of a deleterious atmosphere, for it grows well amid the noxious fumes of the copper-smelting works in Chili, and at one time was considered a useful evergreen shrub for towns. But the plant is seldom seen in gardens; indeed, it is doubtful whether it is hardy out-of-doors in many districts north of the Thames. Another fact which militates against it as an outdoor plant is that it is very slow of growth. But it is suited for the greenhouse or conservatory, and associates well with *Camellias* under glass; it requires a light, peaty soil, and only very little fire heat. Propagation may be effected by means of cuttings of ripened shoots, rooted like those of most hard-wooded plants; but those who attempt this operation must exercise patience, for the shoots are usually several months in rooting.

Coloured Plate.—The subject of the Coloured Plate to be published with our next issue is *Crinum Powellii*.

SALE OF MESSRS. VEITCH'S NURSERY AT CHELSEA.—Messrs. JAMES VEITCH AND SON'S nursery establishment in the King's Road and Fulham Road, Chelsea, will be offered for sale by public auction by Messrs. PROTHEROE AND MORRIS on Tuesday, June 9. The premises, well known as the Royal Exotic Nurseries, have an area of about 2½ acres, and will be offered in one lot, including the office and warehouse.

ROYAL SCOTTISH ARBORICULTURAL SOCIETY.—Arrangements are afoot in Aberdeenshire and the North for the reception of the members of this society, which this year celebrates its diamond jubilee, in their tour of inspection in Scotland. Assembling in Edinburgh on June 27, the members proceed to Perthshire, visiting the Murthly and Atholl woods. Aberdeenshire will be visited on July 1, by way of the Tay Valley to Braemar, when the fine forests surrounding Balmoral Castle and Mar Lodge will be inspected. July 2 will be devoted to Ballogie—the district which, it is understood, the Royal Commission on Forestry has recommended as a demonstration area for the North of Scotland—Finzean and Durris, where the finest woods in Scotland are to be found. The following day the party will leave Aberdeen for Banffshire and Morayshire, where the Seafield woods and the valley of the Spey will have attention. July 4 will also be devoted to other parts of the Seafield forests and the woods around Aviemore. Sunday will be spent at Inverness, and on the following day the party sail down the Caledonian Canal, inspecting the famous forest of Glen Mor on the way, and thence to Oban. Making this pretty little town their headquarters for the next two days, the party visit Inverliever and Poltalloch. Thence they proceed via Lochgilphead, Inveraray, Strachur and Loch Eck to Dunoon. July 9 will see them at Glenfinart and Benmore, and they will return to Edinburgh in the evening. The Corporation of Edinburgh will entertain the members on Friday, July 10, at lunch, and the proceedings will conclude with a reception and official dinner in the evening in the North British Station Hotel.

PHILESIA BUXIFOLIA

A Liliaceous Shrub from Chili ; hardy in favoured districts in Britain.

DAMAGE BY FROST.—The vagaries of our northern climate, writes an Aberdeen correspondent, have been little short of bewildering during the past two months. Following an April of record warmth, May came in cold and chilly, and during the closing week of the month the thermometer on several occasions registered keen frost. The result is that from all over the North come reports of serious damage to the early crops. Potatoes have suffered considerably, and in some districts the Potato crop has been completely ruined. In the great Strawberry growing district of Aberdeenshire (Deeside) the blossom has suffered serious injury. Gooseberries, which gave promise of an abundant yield, are in some quarters reduced to pulp. The same story has to be told of Plums, Pears and Apples.

CROPS ABROAD.—The Board of Agriculture and Fisheries has received the following information from the International Agricultural Institute:—The quantity of Beet sugar, expressed as raw sugar, produced up to the end of March, 1914, in the following countries:—Germany, Austria, Hungary, Belgium, France, Netherlands, Roumania, Russia, Switzerland, Denmark, Italy and the United States, is 8,174,000 tons against 8,303,000 tons produced in the corresponding period of last season, or 98.4 per cent. The cereal crops are progressing under favourable conditions generally in the greater number of the European countries and in the United States. The condition of crops in Russia and Roumania is good, whilst damage caused by drought is reported in Italy, Algeria, Tunis and Egypt. The Crop Reporting Board of Washington, basing its calculations upon the condition of winter Wheat on May 1, estimates the production in the United States at 337,410,000 cwts., against 280,403,000 cwts. in 1913. The vines and Olive trees have passed through the winter without damage in almost all the countries, and their condition is good in Austria, France, Algeria and Tunis, and fairly good in Hungary and Switzerland. The development of the Flax, sugar Beet and Potato crops is, however, generally not so favourable on account of damage caused by drought and frosts.

FRUIT CROPS IN GERMANY.—His Majesty's Consul-General at Hamburg reports that Cherry, Pear and Plum trees flowered abundantly and good crops may be anticipated. There was also an abundant supply of Apple blossom; but, owing to the cold, wet weather trees in many districts have not ceased blooming, and it is impossible at present to say definitely how the crop will finally turn out. Early Strawberries have suffered injury from frost, but from later varieties a good crop is expected. Gooseberries and Currants promise abundant crops.

SCOTTISH HORTICULTURAL SOCIETY'S CHRYSANTHEMUM SHOW.—The secretary informs us that the dates of the annual Chrysanthemum exhibition have been changed from November 19, 20 and 21, to November 12, 13 and 14.

FRUIT AND POTATO CROPS IN BELGIUM.—His Majesty's Consul-General at Antwerp states that Strawberries under glass, especially around Brussels, are reported as satisfactory, but it is expected that Strawberries grown in the open will suffer from the frosts experienced early in May. Throughout the country fruit trees blossomed unusually well, but frosts caused some damage. Apples promise well in the provinces of East and West Flanders, in the south of Limburg, around Herve, Liège, and Lennick St. Quentin, and in the valley of the Meuse. A fairly good crop is expected in the province of Luxemburg, and in the vicinity of Verviers, Namur and La Hesbaye. The frosts destroyed much Apple-blossom in the region of Maeseyck. Pear trees bore a quantity of fruit in East and

West Flanders, the south of Limburg, the valley of the Meuse, and the districts of Lennick St. Quentin, Alost and Tournai. The Plum crop should be good generally, though medium to fairly good in the south of Luxemburg and the districts of Bruges, Verviers, Huy and Namur. Gooseberries and Currants show considerable promise in Flanders, the districts of Malines and Liège and in the valley of the Meuse; they are fairly promising in the other parts of the province of Liège. In the provinces of Namur and Antwerp and in the vicinity of La Hesbaye the crop is expected to be poor. Grapes under glass appear good everywhere. Early Potatoes have suffered to some extent from frosts.

DUTCH BULB INDUSTRY.—According to the report for 1913 on the trade of the Netherlands, issued by Count CHARLES BENTINCK, second secretary to the British Legation at The Hague, the area under regular bulb cultivation in the country was 14,550 acres. Weather conditions were not favourable, but no disease was reported among

that "is the mother of blight." This ubiquitous lady-bird of ill omen it is that "causes the thousands of pounds' damage done annually by blight." The lady-bird, like so many evildoers, takes on many forms: to-day it is the ordinary lady-bird which, cuckoo-like, broods over and hatches out the germs of "blight"; to-morrow it spends a week-end at the sea and takes on a yellower colour—"as the sea-shore Poppies are yellower than the field Poppies." One touch of nature-study makes the whole world kin! Sitting on nests of seaweed our lady-bird hatches out therefrom more blight. Presently the lady-bird assumes the form of the hanneton—the cockchafer so distressful when it buzzes about you in the evening. In short, it would now appear that the heath whereon MACBETH parleyed with the witches must have been blasted by blight begot by lady-birds. The reticence of the writer astonishes us. Having shown that the lady-bird is the only begetter of blight, why should he not continue his interesting demonstration and prove that the dark lady of SHAKESPEARE'S

FIG. 182.—PHILAGERIA VEITCHII: A HYBRID OF PHILESTIA AND LAPAGERIA. (See p. 398, also Supplement.)

the bulbs during the year. The total export of bulbs last year was 24,961 tons, of which 10,192 were consigned to the United Kingdom, both figures showing considerable increases on those of 1911 and 1912. The trade in flowering shrubs was also very favourable. Reports from Germany, Denmark and Norway all pointed to good business in this direction.

A LIBEL ON LADY-BIRDS.—We live in an age so conspicuous for its tolerance that none is surprised to find the blackest character white-washed—HAMLET'S mother proved to be the model of matrimonial rectitude and Judge JEFFREYS an amiable philanthropist. It is the more surprising, therefore, that there should be found among us men bold enough to denounce the crimes of those whom we, in our blindness, had thought hitherto to be innocent. Yet so it is. The news is announced through the medium of the daily Press that our old and valued friend the lady-bird is a villain in disguise. Does "blight" infect your "Beans, Poppies, Sweet Peas, etc."? Then lay not the blame on the narrow shoulders of aphid, for it is the lady-bird

SPEARE'S sonnets is the lady-bird? The most plausible theory with respect to the origin of the communication is that it is a joke designed to test the credulity of the editorial staff. If so, its author must be feeling very happy, for the contribution is hailed by the expert who conducts the gardening page of that journal as "both novel and suggestive," and readers are informed that it is published "with pleasure." The pleasure does not cease there. It will be shared by all who appreciate a jest, and even the lady-birds will laugh at this libel on themselves.

BRITISH-GROWN TOBACCO.—The first or statutory meeting of the Tobacco Plantations Company was held on May 21. The Right Hon. the Viscount HILL, who presided, announced that satisfactory progress had been made in the production of British-grown Tobacco. The committee had in hand over two tons of tobacco for cigarette purposes, manufactured under the supervision of the managing directors, Mr. PULLEN-BURRY and Major WHITMORE. The duty-paid tobacco of the previous crop had been sold at remunerative

prices, and the demand for the company's tobacco was proving most encouraging. In the present year a quarter of a million plants had been raised for the year's planting and for sales, and as soon as rain came they would be planted on the 20 acres of specially prepared land. By sterilisation and the use of the PULLEN-BURRY patent travelling hothouse structure, exceptionally hardy plants had been obtained. Barns had been erected for special curing, but the company would require more capital for further drying sheds to harvest the 20 acres about to be planted.

PARKS AND BOY SCOUTS.—The authorities of the city of Philadelphia, U.S.A., have hit upon the idea of instituting boy scouts as "guardians" of the trees and plants in the public parks. Children, as a rule, seem to take a malicious pleasure in spoiling the flowers and trees, and it may prove the solution of a very difficult problem to institute the boy scouts the official protectors of their playgrounds.

WOMEN GARDENERS IN FRANCE.—A society has been formed at Paris for the furtherance of the agricultural and horticultural instruction of women, by means of lectures and courses of study. The council is composed chiefly of women, but one of the three secretaries, one vice-president, and five members are men.

COLD STORAGE OF FLOWERS.—At Nice a new refrigerating hall has just been constructed in which the temperature can be lowered to 2° above zero. Cut flowers are deposited in this hall as soon as they are gathered, where they are said to retain all their freshness, colour, and perfume for four weeks; in the case of certain kinds, even for six weeks. As they are required the flowers are taken from the store, packed, loaded on refrigerator waggons, and sent abroad. This method goes far to solve the problem of meeting the fluctuating demand of the flower market.

A NEW GARDENING PERIODICAL.—The public will learn with interest of the appearance of a monthly periodical devoted exclusively to gardening. The title of the new monthly is *My Garden Illustrated*, and the pictures of flowers and gardens in the first number fully justify the title. Admirably printed on art paper, the new journal is calculated to appeal to those who contemplate taking up gardening as a hobby, as well as to those who appreciate beautiful garden scenes.

NATIONAL VIOLA AND PANSY SOCIETY.—The first annual exhibition of the National Viola and Pansy Society will be held at Botanical Gardens, Edgbaston, Birmingham, on Wednesday, July 1. The hon. secretary is Mr. J. BASTOCK, Viola House, Springfield Road, Moseley.

FLOWER SHOW AT ALDENHAM PARK.—An exhibition of flowers and vegetables will be held in Aldenham Park, Elstree, on Wednesday, July 8, under the auspices of the Elstree and Boreham Wood Horticultural Society. The hon. secretary is Mr. W. J. PRITCHARD, Elstree.

FREAM MEMORIAL PRIZE.—The Board of Agriculture and Fisheries has awarded a Fream Memorial Prize, of the value of £7 2s. 1d., to Mr. HARRY MUIR MCCREATH, a student of the West of Scotland Agricultural College, Glasgow, who obtained the highest marks in this year's examination for the National Diploma in Agriculture.

PUBLICATIONS RECEIVED.—Circulars from *Purdue University Agricultural Experiment Station*. (LaFayette, Indiana): No. 38, Industrial Clubs and Contests; No. 39, Packing Indiana Apples; No. 40, Report of Poultry Conditions in Indiana; No. 41, Licences for Creameries, and Testers, Laws, Rules and Regulations.—*Agricultural Journal of the Union of South Africa*, Vol. VII., April, 1914. (Pretoria: The Government Printing and Stationery Office.)

XALIS ADENOPHYLLA.

THE charm of this dainty little Oxalis lies in its relatively large flowers and silvery foliage. Unfortunately, at the Chelsea Show, where the species received an Award of Merit (see page 364), the two plants that were shown persistently refused to expand their flowers after the first day, so that it was unnoticed by the majority of the visitors. In the rock garden, exposed to sunshine, the bright, rose-coloured flowers are produced freely, and stand well above the foliage.

BIGNONIA TWEDIANA.

THE accompanying illustration (see fig. 186) will serve to draw attention to one of the most beautiful and effective of stove climbers. It is a strong grower, eminently suitable for decorating the roofs of large stoves or warm con-

HOME CORRESPONDENCE.

ERRONEOUS NOMENCLATURE.—M. Correvon's letter on this subject must surely have the sympathy of everyone interested in the cultivation of hardy plants; for nowadays it is almost impossible to visit a nursery ground or even a flower show without seeing something wrongly named. Having alluded to it before, and to the absurd custom some nurserymen have of calling anything that will grow on a rock or in a bog-garden "Alpine," I hesitate to say more; except to remind my friend M. Correvon that it must be really difficult to find men with the various qualifications of a judge (of, say, a series of beautiful rock-gardens), who are acquainted with the correct names of all the numerous hardy plants now cultivated. In the *Gardeners' Chronicle*, November 29, 1913, some wise remarks bearing upon this subject were made by Mr. Dykes, together with an apt quotation from Dr. Stapf, also made in these columns. *H. S. Thompson.*

NARCISSUS EMPEROR.—I am sending you a few blooms of Emperor Narcissus, as they are

FIG. 183.—OXALIS ADENOPHYLLA: FLOWERS ROSE-COLOURED.

servatories. In the Palm House at Cambridge Botanic Garden it has been a source of great attraction for the past three weeks, its long trails of clear, yellow flowers being very effective. Growing on a pillar, it has now extended to the roof, its numerous pendant branches forming a curtain of flowers. The flowers are bell or funnel shaped, $4\frac{1}{2}$ inches long, limb deeply five-parted, $2\frac{1}{2}$ inches wide at the mouth. The specimen is planted out and grows vigorously. One thing should be especially observed—that whenever pruning becomes necessary during the growing season to keep growth within bounds, the work should be performed with judgment and with due regard to flowering. This will be best effected by a total removal of such portion of shoots as is found necessary rather than a general shortening of all the shoots. This thinning will also greatly assist in the thorough ripening of the flowering shoots, without which there will only be a meagre display of flowers. The species is a native of Buenos Aires. *G. H. Banks.*

unusual at this time of year. I kept the bulbs as dry as possible to prevent them growing, and did not plant them in boxes until February 24. Afterwards they were plunged and grown in the usual way. I shall be able to cut Narcissus flowers for the next fortnight. *A. E. Fox, Beechhurst Gardens, Fairhope, Lancashire.*

FRUIT PROSPECTS IN NORTH ARGYLLSHIRE.—The fruit crops, which until recently were most promising, have suffered considerable damage by severe frost on the night of the 24th ult., when from 5° to 7° Fahr. of frost were registered. Strawberries were in full bloom, and the crop will be a partial failure; Gooseberries and Currant bushes exposed to the sunshine early in the day have the tips of the young shoots severely damaged. Apples, Pears and Plums, being well set, and having ample foliage to protect them, have suffered but little injury. The shoots of early Potatoes have been blackened. Rhododendrons and Azaleas in bloom are much damaged, as also are the young tips of Bay and Portugal Laurels. Some years have elapsed since so much damage by frost has

been wrought in this locality. *Geo. Haig, Barcabline Gardens, Ledaig.*

NEW CHINESE PLANTS.—I am sure that many of your readers must feel deeply indebted to Mr. Beckett for his notes on the newer Chinese trees and shrubs, which have appeared from time to time in your columns, and also for his comprehensive list of these plants published on pp. 344, 372. In the case of many of these plants it must be years before their value for garden purposes is proved, and it is a great help to those who, like myself, have charge of a collection, however small (compared with that at Aldenham) to see them described and discussed in your paper by one who is growing them. I trust that in naming these various shrubs and trees no effort will be spared to see that the proper nomenclature is given, so that confusion may not arise later. From one source we have here a plant named *Lonicera nitida*, and from another source what seems to be an identical plant named *Chamaecerasus piliata*. I only mention this in the hope that the question of proper naming will be given due consideration. *A. T. H.*

THE ROYAL BOTANIC SOCIETY.—I have addressed the following letter to the President, Council, and Fellows of the Royal Botanic Society of London:—"I have recently received the April issue of the *Botanical Journal*, notifying the preliminary programme of arrangements for the coming season at the Society's gardens, and referring also to the appointment of secretary which is about to be made, and I should like to draw the attention of all concerned to the nature of these arrangements and to enquire what principle is being adopted with regard to the secretaryship. The arrangements include three dog shows, a theatrical garden party, the country fair of Our Dumb Friends League, a fancy dress ball, an exhibition of Rhododendrons, the Rose Society's Show and a series of lectures by Professor Bottomley. The fancy dress ball is for the purpose of raising funds for the Society and may or may not be considered as a legitimate method of obtaining money; but of the other arrangements—the Rhododendron Show in a minor degree (being a private traders' exhibition), the Rose show to a somewhat greater extent, and Professor Bottomley's lectures alone touch the objects for which a Royal Charter was granted to the Society. It is common knowledge that the Society has been grievously hampered in the past by injudicious management, and that position has been, I believe, so far recognised that alterations are about to be made in the *personnel*. Under these circumstances, I desire to draw the special attention of the Fellows to the very similar circumstances which were existing in the affairs of the Royal Horticultural Society about thirty years ago. That Society has recently suffered a very heavy loss in the death of Sir Trevor Lawrence, its President for nearly thirty years, and in the obituary notice, published in the last number of the Society's *Journal*, I find the following, which is so remarkably apropos to the affairs of the Royal Botanic Society that I think it worth quoting at some length:—"Called to the President's chair in 1885 in succession to Lord Aberdare, Sir Trevor Lawrence found the Society in very troublous times indeed, attributable to two chief causes: (1) The lavish expenditure on buildings at South Kensington erected on land of which the Society had no proper tenure, and (2) the degradation of the Society caused by a turning away from the pursuit of horticulture to the promotion of London Society entertainments. Sir Trevor's inborn love of gardening taught him at once that a sort of imitation German Biergarten was by no means the ideal for the Royal Horticultural Society to aim at." The lesson learnt was that:—"The Society must return to the policy of its original institution—"Horticulture pure and simple" or the Society must die." The outcome of that lesson was that on the basis of 'Horticulture pure and simple' the Royal Horticultural Society has now a magnificent hall valued at £41,000 and other investments approximating to £70,000. Now, for 'Horticulture' read 'Botany,' and the above excerpt is exactly applicable to the position of

the Royal Botanic Society to-day. The false finance of the Council, which has treated life compositions, for instance, as annual income, and which has seized upon casual receipts from dog shows and theatrical garden parties as fulfilling the end of the Society's existence, has rendered the condition of the Society a parlous one indeed, while, as regards its scientific status, it is verily the laughing-stock of the botanical world. The main object of this letter is to appeal to the Council and the President that in the impending appointment which is to be made, a single eye should be given to the scientific side of the work of the Gardens, eliminating as soon as possible the purely social use of the grounds, about which questions have, I think, already been asked in Parliament, and in the second place, that immediate steps should be taken to reconstitute the governing body of the Society upon a basis that would command the respect of

(Photograph by W. Irving.)

FIG. 184.—ANOPLANTHUS COCCINEUS PARASITIC ON CENTAUREA DEALBATA.

botanists and business men. I think that if this were done and members added to the Council really representative (in the words of the Charter) of 'the promotion of botany in all its branches and its application to medicine, arts, and manufactures,' a very effective appeal might be made for funds to those interested in the development of the agricultural resources of the Empire, who would be prepared to recognise the importance of an institution, not wholly official like Kew, not floricultural like the sister society in Vincent Square, but solely and entirely concerned with economic botany and its advancement both at home and overseas." I beg to remain, your obedient servant, *Stuart R. Cope (Fellow).*

"LOCAL NAMES."—In your review of Mr. Horwood's book (p. 347) you refer to the author as having "collected many of the local names of British plants." I shall be glad if you will

allow me to point out that those names are transferred bodily—often incorrectly and always without acknowledgment—from the *Dictionary of English Plant Names*, published by the late Robert Holland and myself in 1878-86. *James Britten.*

—In his review of my book, *Plant Life in the British Isles* [in the *Journal of Botany*], Mr. Britten commented at length upon the English names there given, which were taken from the *Dictionary of English Plant Names*, the main, though not the only, source of information upon this interesting side of botanical knowledge. I regret that by inadvertence the work was not included in my list of authorities consulted. But this is being remedied in a subsequent volume by due acknowledgment, and any misprints in the volume reviewed will be corrected in a subsequent edition. I also wrote to Mr. Britten when his review appeared. *B. R. Horwood.*

WISTARIA AT SYSTON HALL.—The illustration in fig. 185 shows the main stem of an old plant of *Wistaria sinensis* growing in the conservatory at Syston Hall, near Grantham, the seat of Sir John Thorold, Bart. The stem and branches have become a knotted mass, and the former appears to be almost a part of the iron pillar around which it is entwined. The tree is said to be the first plant that was brought to this country; it is certainly of great age and very interesting in appearance. *W. H. Divers, Belvoir Castle Gardens.*

NARCISSUS FLIES.—I can endorse Mr. Shea's recommendation (see p. 375) to Daffodil growers to read the very excellent article on *Narcissus flies* in the May number of the *Journal* of the Board of Agriculture, and the statements he quotes deserve all the consideration due to their authoritative appearance. There are, however, no new facts given in proof. The statements are apparently a reiteration or quotation of the original *ipse dixit*, and they can therefore, I think, hardly be held to be in any way confirmatory of those views. The theory that the Eumerus attacks and feeds on sound Daffodil bulbs is, then, still as much as ever a theory, and if it were allowed to go unchallenged and unverified we might be put to considerable trouble that eventually might prove to have been unnecessary. But after all there is just one new fact mentioned in the above article which I will quote, leaving your readers to form their own conclusions as to its significance. "In the preliminary experiments carried out in 1915, bulbs in the ground, and also uncovered in the store" (presumably sound bulbs) "were exposed to flies of the second brood, but were in no case attacked." *A. J. Bliss.*

ANOPLANTHUS COCCINEUS.

This remarkable parasite of the Natural Order Orobanchaceae (see fig. 184) is a native of the Caucasus, where it grows on the roots of various plants, but chiefly on *Centaurea dealbata*. The beautiful silvery foliage of the host plant acts as a delightful foil for the large velvety flowers, which are of a brilliant scarlet colour. They are about 2½ inches in diameter, and are borne singly on reddish-brown stems from 12 inches to 18 inches high. The stems are naked with the exception of two or three bracts on the lower halves. The flowers, which resemble those of a giant *Lobelia*, are five-lobed, with two upper and three lower lobes, the latter forming a lip at the base of which is a large black blotch. The plant illustrated was grown in Kew Gardens from seeds received from Tiflis Botanic Garden in the spring of 1911. The seeds were sown, together with those of the host plant, in a pot. Only the *Centaurea* appeared, and this was planted out in the rock garden the same year. Nothing else came up till this year, when seven stems of *Anoplantus* were noticed early in May, each with a solitary flower bud, the first flower opening about the middle of the month. It is a very attractive plant, and promises to remain in bloom for some time. This is probably the first time that the species has flowered in cultivation, as it has not been recorded before. *W. L.*

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 3.—On account of the Whitsuntide holidays the usual fortnightly meeting was held on a Wednesday instead of the customary Tuesday. The attendance was below the average, but many of the exhibits reached a high standard of excellence. In view of the lecture on Irises by Mr. W. R. DYKES, these flowers were shown by several exhibitors, and shared with *Papaver orientalis*, herbaceous Paeonies, and Sweet Peas the especial admiration of the visitors. More than 50 new plants were submitted to the Floral Committee for award, and of these 19 were recommended for Awards of Merit. This Committee awarded 1 Gold and 31 other Medals to collections.

The Orchid Committee made no awards to new plants.

The Fruit and Vegetable Committee awarded a Silver Banksian Medal to a collection of Melons.

At the 3 o'clock meeting in the lecture room, Mr. W. D. DYKES delivered a lecture on "Irises."

Floral Committee.

Present: H. B. May, Esq. (in the chair). Messrs. G. Reuthe, W. J. Bean, J. Green, J. W. Moorman, J. F. McLeod, Wm. Howe, W. Bain, C. R. Fielder, John Dickson, Chas. E. Shea, J. T. Bennett-Poë, Arthur Turner, W. Cutbertson, W. P. Thomson, George Paul, E. H. Jenkins, W. A. Bilney, E. A. Bowles, F. W. Harvey, John Jennings, Charles Blick, and R. W. Wallace.

AWARDS OF MERIT.

Iris chrysographes.—A grassy-leaved species introduced recently through E. H. Wilson from China. Its round, hollow stems grow about 2½ feet high and carry flowers of a richer and deeper shade of velvety violet-purple than any other species, with one central line of gold down the falls and a few variable dots of gold at the throat. The form of the flower, with its long, hanging falls, reminds one of *I. Delavayi*, but it is more beautiful. Shown by Mr. W. R. DYKES and Miss WILLMOTT.

Iris Iota.—This is a hybrid between *I. tenax* and *I. Purdyi*. It has long, grassy, arching foliage and very daintily-formed flowers of a lilac shading and veining on a white ground. The standards are lanceolate and erect, the falls oblong-cuneate and horizontal. Each stem bears two flowers, and a two-year-old plant was said to be carrying forty spikes. This was shown by Mr. W. R. DYKES, with a number of other hybrids, of which the most distinct were *Epsilon* (*Bulleyana* × *Forrestii*), the tallest grower, cream and yellow ground dotted blue; *Eta*, a remarkable red bracteata; *Beta* (*chrysographes* × *Forrestii*); *Gamma* (*Forrestii* × *chrysographes*); *Theta* (*tenax* × *Wilsonii*); and *Zeta* (*sibirica* × *Wilsonii*).

Iris laevigata alba.—This is the white form of the true *Iris laevigata* and distinct both in foliage and form of flower from *I. Kaempferi*, which is so often confused with it. The flowers are pure white, showing a tinge of mauve at the base of the standards and style arms. It grows about 18 inches in height and has the same distinctive form as the better known *Iris albo-purpurea*.

Iris sibirica Emperor.—A noble form of *I. sibirica*, of Japanese origin. The falls are large and circular, and the whole flower is of a deep violet-blue. The habit is tall and erect, carrying the flowers well above the foliage. It may best be compared with *I. sibirica orientalis*, which is dwarf-habited and has distinctive red spathes as well as a patch of white at the throat, which *Emperor* lacks.

Iris Kashmir White.—The most beautiful of the white hybrid Irises we owe to the late Sir Michael Foster. The flower-stems rise 4 feet high and carry six large, pure-white flowers. It is a variety of the bearded *Iris kashmiriana*, but is distinct from the so-called Sheldford variety of that species (or *Miss Willmott*), which flowers less freely and often has its flowers washed with pale blue. In the beard and throat veining it shows a touch of yellow.

These three were shown by Messrs. R. WALLACE AND CO., Colchester.

Lupinus Primrose Dame.—A handsome seedling of *L. arboreus*, with flower-spikes nearly 18

inches long of the palest primrose. Shown by Messrs. BARR AND SONS.

Strain of Lupinus polyphyllus.—Messrs. BARR also showed a splendidly-grown collection of named sorts of *Lupinus polyphyllus*, which were recommended as a strain for the Award. They varied from palest lavender-white, through lavender to mauve, blue and purple, with some very striking seedlings like *Eastern Queen* showing arboreal blood in the yellow standards above slaty-blue wings. *Nellie*, *Dainty*, *The Bride*, *Taplow Pink* and *Ophir* were among the best-named sorts.

Strain of Aquilegia.—Mrs. SCOTT-ELLIOTT, Teviot Lodge, Hawick, won the Award for her well-known strain of long-spurred Columbinas. They were badly shown, with very short stalks, but included a splendid range of colour through creams, pinks, reds, lavenders, whites and blues.

[Photograph by W. H. Divers.]

FIG. 185.—STEM OF WISTARIA IN THE CONSERVATORY AT SYSTON HALL.
(See p. 401.)

Carnation Mrs. Brotherton.—A white ground fancy border variety, heavily suffused and dotted with crimson. The flowers were large and well formed.

Carnation Robert Bruce.—A distinct self-border variety with orange-salmon or terra-cotta flowers. A fine colour and full of substance.

Carnation Mrs. Griffith Jones.—A warm apricot self border variety, softer in colour than the last, rather thinner and with smoother petal.

These three were shown by Mr. JAMES DOUGLAS.

Strain of Antirrhinum.—A handsome collection of named varieties, shown by Messrs. DOBBIE AND CO., were recommended an Award of Merit. They belonged to the Intermediate section, averaging about 20 inches in height, and showed a range of colour especially rich in yellow

and orange. *White Beauty*, *Yellow Queen*, *Primrose Queen*, *Moonlight*, *Amber Queen*, *Maize Queen* and *Dobbie's Scarlet* were some of the best.

Papaver Lady Frederick Moore.—This is a variety of *P. bracteata* with pale, salmon-pink coloured flowers of the largest size, with dark basal blotches, held finely on stout, erect stems. In colour it is very close to *Princess Victoria Louise*, but in size, form and habit it is a marked improvement. Shown by Mr. AMOS PERRY.

Clematis Sieboldii (see fig. 187).—This is a distinct climber with a neatly-formed white perianth of six segments showing off finely a central mass of purple linear modified barren stamens. The flowers are about 3½ inches in diameter, and the purple centre 1½ inch. They appear to be always solitary in the leaf-axils, but a pair of variably-lobed bracts is borne a few inches below the perianth.

Verbascum Warley Rose.—Flowers bright rose-pink, with purple-haired filaments, held finely well above the foliage in a richly branched panicle. This is the finest perennial mullein we have seen. In habit it reminds one of *vernale*, and the flat, basal rosette of smallish leaves suggests the possibility of phoeniceum influence. The individual flowers are 1½ inch in diameter, and the plant grows about 5 feet.

These two shown by Miss WILLMOTT, V.M.H.

Mimulus Wargrave Fireflame.—A dwarf moisture-loving Musk, with large, unblotched flowers of a glowing orange-red. The height is only 6 inches. Shown by Messrs. WATERER, SONS AND CRISP, LTD.

Ribes Brocklebankii.—This is a pretty form of the dwarf species, *R. alpinum*, with foliage entirely of a bright yellow. Growing only 12 or 18 inches in height, it should prove useful to give a mass of bright colour in bedding.

Deutzia discolor elegantissima.—A charming dwarf shrub of about 2 feet only, with gracefully arching branches clothed with neat, wrinkled, and finely serrate leaves, from the axils of which rise the corymbose bunches of twenty or more flowers. The blooms are a pretty shade of lilac pink, and are individually about ¾ inch in diameter.

These two were shown by ELIZABETH Lady LAWRENCE, Dorking (gr. Mr. W. Bain).

Erigeron hybridus B. Ladhams.—An interesting form with stiffly erect habit. The flowers are a mauve-pink, about 1½ inch in diameter, borne in few flowered cymes, at a uniform height of about 2 feet. Shown by Messrs. B. LADHAMS, Shirley.

GENERAL EXHIBITS.

R. KEEP, Esq., Woollet Hall, North Cray, Kent (gr. Mr. S. Pym), showed a group of *Carkias* which evidenced first-rate cultivation. (Bronze Banksian Medal.)

Mrs. A. V. LITKIE, Clarendon, Maidenhead (gr. Mr. W. Hulbert), exhibited *Clarendon Gem Hybrid Calceolarias*. (Bronze Flora Medal.)

Messrs. H. B. MAY AND SONS, Upper Edmon-ton, showed various *Hydrangeas*, *Verbenas*, *Lantanas*, and *Heliotrope* in small pots. (Silver Banksian Medal.)

MESSRS. GODFREY AND SONS, Exmouth, Devon, exhibited especially good show and fancy *Pelargoniums*, and a great many of the scented-leaved varieties in pots. (Bronze Banksian Medal.)

Mr. L. R. RUSSELL, Richmond, showed bedding *Pelargoniums*, *Heliotropes*, dwarf *Lantanas* and *Salvias*. (Bronze Banksian Medal.)

MESSRS. JOHN PEED AND SON, West Norwood, contributed *Streptocarpus* and *Gloxinia* of good strains. (Bronze Banksian Medal.)

MESSRS. R. AND G. CUTBERT, Southgate, arranged an effective group of standard *Fuchsias*, Ivy-leaved *Pelargoniums*, *Streptosolon Jamesonii* and other plants in the annexe. (Silver Flora Medal.)

MESSRS. WM. CUTBUSH AND SON, Highgate, displayed an interesting collection of *Hydrangeas*, various *Crozy Cannas*, and hardy border flowers.

Mr. H. BURNETT, Guernsey, had a splendid collection of cut *Carnation* blooms. A central vase of *Snowstorm*, flanked by *Pluto* and *Monarch*, was especially charming. (Silver Flora Medal.)

MESSRS. STUART LOW AND CO., Bush Hill Park, Enfield, had a bold arrangement of *Carnations*. The chief varieties were *Gorgeous*,

Baroness de Brienem, and Princess of Wales. (Bronze Flora Medal.)

Mr. CHAS. BLICK, Hayes, Kent, had a small collection of good and fresh Carnation blooms.

Mr. J. DOUGLAS, Great Bookham, Surrey, showed especially fine Carnations; his chief varieties were Elizabeth Shifner, Rosy Morn, Cecilia and Virginia. (Silver Flora Medal.)

Mr. C. ENGELMANN, Saffron Walden, also showed a good collection of Carnations. (Bronze Flora Medal.)

Messrs. DOBBIE AND Co., Edinburgh, exhibited excellent Sweet Peas, which were arranged with great skill and taste. The principal varieties were Frilled Pink, Thomas Stevenson, Illuminator, Norma and Royal Purple. Adjoining this exhibit Messrs. DOBBIE displayed Antirrhinums of almost greater excellence. The long spikes, well furnished with large blooms of delightful colours, made a most attractive exhibit, and not only were the varieties uncommonly good, but their names were descriptive. Maize Queen, Bonfire, Cottage Maid, Amber Queen and Yellow Queen are the names of a few of the varieties so well shown. (Gold Medal.)

Messrs. R. H. BATH, LTD., Wisbech, showed an attractive collection, including such Sweet Peas as Glow, Thomas Stevenson and Agricola in very good condition. Next to these flowers Messrs. BATH exhibited Tulips, chiefly Darwin and Cottage varieties, in bright colours and of size. (Silver Flora Medal.)

Messrs. ALEX. DICKSON AND SONS, Newtownards, Ireland, included a new seedling of intense, almost pure scarlet colour in a noteworthy collection of Sweet Peas. (Silver-gilt Banksian Medal.)

Messrs. E. W. KING AND Co., Coggeshall, Essex, arranged a collection of Sweet Peas, said to have been cut from the open ground. The fresh blooms were of good size and clear colours. (Silver Flora Medal.)

Messrs. S. BIDE AND SONS, Farnham, Surrey, displayed many standard varieties of Sweet Peas and included Phyllis Bide, a deep orange-coloured flower. (Silver Banksian Medal.)

Mr. E. J. HICKS, Hurst, Berks, in a large exhibit gave especial prominence to the charming Rose Princess Mary, which received the highest award at the recent spring Rose Show. Stands of Mrs. Ed. Alford, Comtesse de Cayla and Irish Elegance were also very beautiful. (Silver Flora Medal.)

Messrs. H. CANNELL AND SONS, Eynsford, Kent, arranged a very attractive display of Wichuriana Roses, using floriferous plants in relatively small pots. (Silver Banksian Medal.)

Messrs. W. J. BROWN, Peterborough, showed a new pillar Rose, Mrs. Rosalie Wrinch, and other varieties, amongst a collection of hardy herbaceous flowers, which included magnificent spikes of Eremuri.

Messrs. FRANK CANT AND Co., Colchester, contributed cut and pot Roses, specialising with such sorts as Austrian Yellow, Irish Elegance and Rosa sinica Anemone. (Silver Flora Medal.)

Mr. GEORGE PRINCE, Oxford, showed flowering shoots of Rosa hemisphaerica, R. alpina and R. sinica Anemone.

Messrs. B. R. CANT AND SONS, Colchester, contributed a good collection of Roses. Cupid, a very large single-flowered variety, which appears to be unusually free-flowering, promises to be a valuable garden Rose. When fully expanded the colour is blush-pink; in earlier stages the colour is a charming combination of amber and terra-cotta. (Silver-gilt Banksian Medal.)

Messrs. BARR AND SONS, Covent Garden, London, displayed herbaceous Lupins in a wide range of distinct colours. Vases of Liliun monadelphum Szovitzianum, Iris germanica varieties, and a wide bordering of Nepeta Musinii added to the attraction of the group. (Silver-gilt Banksian Medal.)

Messrs. KELWAY AND SON, Langport, Somerset, exhibited a collection of herbaceous Paeonies and Pyrethrums, which, with a few vases of Delphiniums, filled a length of tabling. Most of the Paeonies were single-flowered varieties, and they displayed many beautiful colours. (Bronze Flora Medal.)

Messrs. R. WALLACE AND Co., Colchester, showed many exceedingly good garden Irises. Amongst the germanica section the varieties with blue shades and those with combinations of orange and purple were exceedingly decorative. Vases of Eremuri, Liliun monadelphum

and Habranthus pratensis, the last-named being exceptionally fine, were also admirable. (Silver Banksian Medal.)

Messrs. GODFREY AND SONS, Exmouth, Devon, contributed a collection of new varieties of Papaver orientalis.

Messrs. PHILLIPS AND TAYLOR, Bracknell, Berkshire, grouped Papaver orientalis and Trollius Orange Globe around a small Lily pool, which was margined with moss and rushes. (Silver Banksian Medal.)

Mr. JAMES BOX, Haywards Heath, Sussex, filled a corner of the hall with many desirable border flowers, arranged with taste. (Silver-gilt Banksian Medal.)

Messrs. JOHN WATERER, SONS AND CRISP, Liverpool Street Arcade, London, included several desirable Irises in an attractive exhibit of hardy herbaceous flowers, and in another part

FIG. 186.—BIGNONIA TWEEDIANA: FLOWERS YELLOW. (See p. 400.)

of the hall showed Rhododendrons. (Silver Flora Medal.)

Messrs. J. VEITCH AND SONS, Chelsea, displayed Eremuri, Iris germanica hybrids, Polygonum alpinum, Primula capitata and Thalictrum aquilegifolium roseum in a collection of hardy flowers.

Mr. G. REUTHE, Keston, Kent, exhibited Rhododendrons and other flowering shrubs and Alpines. (Bronze Banksian Medal.)

Messrs. GEO. JACKMAN AND SON, Woking, contributed many good Irises, chiefly germanica varieties, Lupins, Delphiniums, and other hardy flowers.

Messrs. B. LADHAMS, LTD., Southampton, exhibited a large number of Erigeron B. Ladhams, which received an Award of Merit.

Messrs. W. WELLS AND Co., Mersham, Surrey, showed Antirrhinum Nelrose and Carnation Cecilia.

Messrs. J. CHEAL AND SONS, Crawley, exhibited sprays of hardy shrubs. The vases of

Golden Elm (Ulmus Dampieri aurea) and of Kalmia rubra were very effective.

Mr. C. W. CHANTLER, St. Mary Cray, Kent, showed Irises and hardy flowering shrubs in great variety.

Messrs. T. S. WARE, LTD., Feltham, Middlesex, displayed border flowers, chiefly of Irises and Pyrethrums. (Bronze Banksian Medal.)

Messrs. CARTER PAGE AND Co., London Wall, London, anticipated the season and showed Dahlia blooms in variety. (Bronze Banksian Medal.)

Messrs. G. AND A. CLARK, Dover, arranged an attractive group of hardy border flowers on a floor space. (Bronze Banksian Medal.)

Mr. AMOS PERRY, Enfield, showed a great many varieties of Papaver orientalis, of which those with bright red flowers were exceedingly attractive. (Silver-gilt Banksian Medal.)

Mr. G. W. MILLER, Wisbech, included many herbaceous Pyrethrums in his group of hardy flowers.

Mr. C. ELLIOTT, Stevenage, Herts, and the Misses HOPKINS, Shepperton-on-Thames, exhibited rockery plants; and Messrs. GILBERT AND SON, Dyke, Lincolnshire, showed St. Brigid Anemones

Orehid Committee.

Present: J. Gurney-Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. secretary), Gurney Wilson, De B. Crawshay, W. Bolton, R. A. Rolfe, F. Sander, J. Wilson Potter, T. Armstrong, A. McBean, W. Cobb, J. Charlesworth, W. H. Hatcher, J. E. Skill, C. H. Curtis, A. Dye, E. H. Davidson, S. W. Flory, W. Bolton, Sir Harry J. Veitch and Sir Jeremiah Colman, Bart.

There was a good show of Orchids in the various groups staged, but although about a dozen novelties were entered to go before the Committee, no awards were made.

Messrs. CHARLESWORTH AND Co., Haywards Heath, staged a group composed entirely of well-grown specimens of new or rare plants, the most beautiful of which were the varieties of their new Miltonia Charlesworthii and of their handsome forms of home-raised M. vexillaria named Lyoth. Some fine Odontoglossums, Odontodas, Cattleya Mossiae Wageneri King Edward VII. (one of the finest white forms of Mossiae), good Laelio-Cattleyas, Sophro-Laelio-Cattleya Niobe and a fine example of the rose-pink Dendrobium acuminatum were also included. (Silver Flora Medal.)

Messrs. SANDER AND SONS, St. Albans, staged a group, rich in new species and finely-flowered hybrids. The centre was of Laelio-Cattleya Fascinator, of excellent shape and tint, and varying much in the colour of the labellums. Good L.-C. Canhamiana and L.-C. Hyeana; a very nice lot of Odontoglossums, Odontodas, etc., including the finely-coloured O. militaris; a selection of Cattleya Mossiae, Bulbophyllum virescens and other Bulbophyllums, including a very singular, undescribed species from New Guinea, were also noted. Among new and specially interesting things were the pretty red Adioda St. Fuscien, Laelio-Cattleya Sylph (L.-C. Hippolyta x C. Mossiae) of C. Mossiae shape, but of nankeen-yellow colour tinged with rose, and rose-purple lip; L.-C. Dryad (L.-C. Martinetii x C. Schröderae), pale buff flushed with rose and with purple-veined lip. The handsome Cypripedium Roger Sander and other Cypripediums were also shown. (Silver Flora Medal.)

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), staged a very interesting group in which were many species now becoming rare. Anguloa Ruckeri, A. Clowesii, the elegant Oncidium pulchellum and O. phymatochilum, various Masdevallias, among which were two specimens of M. muscosa, with labellums which sprung upward on being touched; a good lot of Miltonia vexillaria and M. Bleuana, Chondrorhyncha Chestertonii and Bulbophyllums. The Laelio-Cattleyas and Cattleyas included several pretty things raised at Rosslyn; and a good selection of varieties of Odontoglossum crispum, O. Wigmanum, O. percutum, Odontodas, etc., were also noted. Cymbidium Sappho (Lowianum Pitt's var. x T'Ansonii), raised at Rosslyn, adheres closely to T'Ansonii. (Silver Flora Medal.)

Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, were awarded a Silver Flora Medal for a group in which were examples of their new blotched *Odontoglossums* *eximillus* and *ardentillus* and other fine hybrids. *O. Leonidas* was a beautiful yellow flower with chestnut-brown blotches and of fine size. A selection of *Miltonias*, *Brasso-Cattleyas*, *Brasso-Laelias*, white-petalled *Cattleya Mendelii*, and pretty *Laelio-Cattleyas* were also included, together with brightly-coloured *Odontiodas*, etc.

Messrs. STUART LOW AND Co., Jarvis Brook, Sussex, had an effective group of fine forms of *Cattleya Mossiae* and *C. Mendelii*, including several white varieties. *C. Mendelii* Fairy Queen was a pretty white-petalled form, and one had an effective purple band on the petals. Their

novelty raised by the firm was *Cattleya Sibyl* (*iridescens* × *aurea*), of the form of *C. Iris*, with fragrant, bronzy-yellow sepals and petals tinged with rose and bright ruby-red lip with yellow disc. (Silver Banksian Medal.)

Messrs. J. AND A. McBEAN, Cooksbridge, had an effective group of finely-grown *Cattleyas*, including the large *C. Mossiae* St. Bernard and the white *C. M. Wageneri* with eight flowers. *Odontoglossum crispum xanthotes* McBean's variety was pure white with some chrome-yellow spots and of model form; *Brasso-Cattleya Irene* (*Mossiae* × *Digbyano-Warneri*) was a fine rose flower; *Laelio-Cattleya Helius*, yellow with a red front to the lip, and some brightly-coloured *Odontiodas* were noted. (Silver Banksian Medal.)

Messrs. FLORY AND BLACK, Slough, staged a

G. W. BIRD, Esq., Manor House, West Drayton (gr. Mr. Redden), showed *Odontioda Phyllis* (*Odm. Lambeauanum* × *Oda. Bradshawiae*), cream-coloured with red markings, and with rose lip having a few red blotches; and *Odontoglossum ardentissimum* Manor House variety, a large, darkly-blotched flower.

Col. S. R. CLARKE, C.B., Borde Hill, Cuckfield, showed *Odontoglossum Ethelreda* Borde Hill variety (*trumphans* × *Edwardii*), with blackish-purple flowers.

Sir MONTAGU TURNER, Bedford, Havering-Essex (gr. Mr. A. Humphrey), sent a light form of *Cattleya Mendelii*.

W. P. BURKINSHAW, Esq., Hessle, Hull, sent *Brasso-Cattleya Rex* (*C. Rex* × *B. Digbyana*), with flowers larger than *B. Digbyana* and with a yellowish-green tint, but closely adhering to *B. Digbyana*.

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq., in the chair; Messrs. Jos. Cheal, W. Bates, J. Willard, E. Beckett, Horace J. Wright, A. Bullock, Owen Thomas, and Wm. Poupert.

The only exhibit before the committee was a collection of Melons shown by C. ERIC HAMBRÖ, Esq., Pickhurst Mead, Kent (gr. M. C. Davis). The fruits, which were of the variety *Sedgewick Gem*, were of large size, scarlet flesh, and of rich flavour. (Silver Banksian Medal.)

IMPERIAL HORTICULTURAL SOCIETY OF ST. PETERSBURG.

INTERNATIONAL EXHIBITION.

THIS Society, which was founded in 1862, is distinguished by the patronage of his Imperial Majesty the Czar of Russia. The present International Exhibition is the fourth which has been held since the establishment of the Society. It was intended to hold it last year, to celebrate the Jubilee of the Society, but the fact that the Ghent Quinquennial Exhibition occurred in 1914 led to its postponement.

The permanent exhibition building in the Touride Garden was presented to the Society by the Czar. On either side of the entrance hall were committee rooms, and above it was a restaurant. The main central hall was roofed with glass. Although not yet completed, it was sufficiently finished for the present Exhibition. At the extreme end an annex has been erected, which will probably be covered with glass. The building, when complete, will be connected with a hall in which will be shown the exhibits from the Imperial schools of horticulture, agriculture, and arboriculture. From one end of the main hall good views of the gardens were to be obtained, and the design, which suggested French influence, was very attractive. There were various smaller halls, many erected by individual exhibitors.

It may be well to preface remarks on the exhibits by the observation that the backwardness of the season, and the exceptional severity of the past winter, have had a serious effect on the outdoor plants. Dutch growers planted about a million bulbs, chiefly *Hyacinths* and *Tulips*, but very few of the former were visible, and thousands of the latter failed. Those plants which have struggled into growth were much below standard and small in flower. Some attempt had been made to cope with this unfortunate situation by planting *Rhododendrons*, which looked at first sight like the common *R. ponticum*, but which closer examination proved to be *R. catawbiense floribunda*. Most British gardeners would probably call them merely good *potenticum* seedlings; but they certainly have done good work in filling the gap left by the bulbs. It was remarkable that everywhere the ground was brown earth or yellowish sand and that grass was almost absent.

The unfinished brick walls of the main hall were effectively screened by scenic paintings, and here and there were grouped magnificent Palms from the Imperial Gardens. One of these plants was a splendid specimen of *Caryota Rumphiana* about 30 feet high, and another a fine example of *Ceroxylon niveum*, 25 feet in height, with eight perfect leaves. The centre of

FIG. 187.—CLEMATIS SIBBOLDII.
(See Floral Committee's Awards, p. 402.)

fine type of *Dendrobium formosum giganteum*, *Phalaenopsis Rimestadiana*, *Renanthera In-schootiana*, *Miltonia vexillaria* and *Oncidium varicosum* were all effectively displayed. The best novelty in the group was *Laelio-Cattleya Damos* (*L.-C. Dominiana* × *C. Mossiae*), a very large and handsome deep-rose flower with broad claret-purple lip with yellow lines from the base. (Silver Flora Medal.)

Messrs. HASSALL AND Co., Southgate, had a pretty group with *Laelio-Cattleya Fascinator* and other *Laelio-Cattleyas* in the centre, the ends being of the large-flowered type of *Miltonia vexillaria* with some hybrid *Miltonias* and *Odontoglossums*. Among white-petalled *Cattleyas*, *C. Mossiae* *alba* *Empress Eugenie* was a very fine flower, and *C. M. Hardyana* one of the best of the *Reineckiana* class. A pretty

selection of good hybrids, one of the novelties being *Brasso-Laelio-Cattleya Albatross* (*B.-L. Digbyano-purpurata* × *C. Mossiae*), a broad white flower with a pink tint on the fringe of the lip; *Laelio-Cattleya Aphrodite*, with white sepals and petals, and other *Laelio-Cattleyas*; two *Cattleya Mossiae* *Wageneri*, several *C. M. Reineckiana* and various *Miltonias*.

R. G. THWAITES, Esq., Chessington, Streatham, showed a selection of hybrids including *Odontiodas* and *Laelio-Cattleyas*, together with three home-raised specimens of *Cattleya Mossiae* *alba*.

Baron BRUNO SCHRODER, The Dell, Englefield Green (gr. Mr. J. E. Shill), showed *Odontoglossum crispum* *The Dell Sunrise*, a remarkable white flower of very thick substance, the petals having a narrow red margin.

The hall was occupied with a very creditable display of Roses in pots, sent by a local nurseryman, Mr. FREUNDLICH, who has one of the largest nurseries in this part of Russia. At the extreme end of this central block an excellent group of Ferns afforded a good setting to masses of Lilacs and Hydrangeas (here known as "Hortensias"). A group of fine Palms from AUG. TROEFFART, Budebrügge, occupied one end, the best plants being *Brahea glauca*, *Cocos Bonnetii*, *Kentia Forsteriana robusta*, and *Phoenix Roebelenii*. DE SMET FRERES also showed several large plants of *Areca Baueri*.

In the left hall on the ground floor a group of Cycads was well arranged, comprising well-grown specimens of *Encephalartos Lehmanni*, *Cycas*, *Dioon edule*, *Encephalartos Hildebrandii*, *E. villosus*, *E. Altensteinii*, *Macrozamia spiralis*, *Ceratozamia mexicana*, *C. robusta*, *C. longifolia*, and others. These fine plants were sent from the Imperial Botanic Gardens. An excellent group of Bromeliads was also shown in this hall, and a bank of good specimens of *Phoenix Roebelenii*. On the floor above there was a mixed group of smaller plants, including *Hippeastrums*. Some fine groups of cut Carnations were shown by Mr. C. ENGELMANN, of Saffron Walden, including about fifty varieties. On the central table there was also an exhibit of Carnations, from a German firm.

In the corresponding hall on the right-hand side of the entrance, the French growers made an excellent display. There were Apples, including *Calville Blanc*, *Grand Alexandre*, and *Reinette Blanche du Canada*, and quantities of Pears of large size and good quality. Boxes of Cherries and preserved fruits also made a good show. These exhibits were chiefly from the *Société Regionale d'Horticulture Montreuil de Bois*. MESSRS. VILMORIN, ANDRIEUX AND Co. showed their strains of florist's flowers, and MESSRS. HENRI VACHEROT AND LECOMTE Orchids. M. GEORGES TRUFFAUT, of Versailles, showed a most interesting exhibit of a scientific nature. The educational side of the French section was generally admirable; and the floral designs were beautifully executed.

The central part of the annexe was filled with huge vases and baskets of Roses and Lilacs. Around the side tables were vegetables in great variety, shown in an attractive and essentially un-British style. Cucumbers were present in large quantities, green, yellow and white; also excellent Cauliflowers, Beetroots, Carrots old and young, and Potatoes. Onions were well represented, and Cabbages red and white, but no green ones. Tomatos were numerous and of good quality, and it was interesting to note exhibits of Fennel grown as a culinary vegetable.

Outside the annexe were beds of Show and Zonal Pelargoniums. *Lilium longiflorum* made a brave show, and Hydrangeas provided an attractive piece of colour. There were also beds of *Cocos Bonnetii*, with *Araucaria excelsa* as dot plants; but the prettiest and most graceful exhibit was a bed of common Foxgloves in bloom. They were grown in pots, and made a charming display in the grounds. On the right side of the main path leading from the terrace was an arrangement of a mixed character. A pond had been constructed with edges of cement. There were several small islands, and on the sloping banks a carpet bed, representing a coat of arms, had been made. Above this, further back, was a quantity of virgin cork, furnished with Ivy, Club Moss—*Lycopodium clavatum*—and Hydrangeas, with Ferns, Agaves, and other plants—apparently, anything that came handy. In the centre a small cascade had been arranged, which flowed into the pond.

Throughout the grounds there were numbers of beds of *Lilium longiflorum*, Hydrangeas (in great numbers), *Cinerarias*, *Rhodanthes*, *Spiraea* (*Astilbe*), *Violas* and fancy *Pansies*, these latter being utilised to fill up spaces where the Tulips had failed. The only attempt at rock gardening consisted of an arrangement in front of the Hall of Agriculture and Horticulture. Groups of Conifers helped to furnish the grounds, and were effective; there were apparently no novelties among them, but some of the specimens were good. Unfortunately, many showed traces of the ill effects of packing and transport. In some cases the young growths were bleached quite white. Trained fruit trees—chiefly from France—were much in evidence, and were uniformly excellent. An interesting outdoor exhibit came

from the Botanical and Experimental Gardens of Stockholm. The plants comprised in this group looked at first sight like small-leaved Laurels, but proved on examination to be Tea plants (*Thea*), some seven or eight varieties of which were represented. The plants are grown out-of-doors in the summer in Sweden. Mixed beds of greenhouse plants, a bed of several species of Citrus, some of them in flower, a bed of Bamboos, and another of fruit trees, were interesting and ornamental.

In a central bed were a number of Agaves, *Opuntias*, and *Yuccas*. Near this exhibit were the sundries; for example, glass-houses, boilers, and various gardening appliances. A curious exhibit consisted of a mound of turf about 10 feet high with sloping front, on which was formed a carpet bed, the design being a portrait of the first of the Romanoffs. It was really wonderfully well done, though "not gardening."

We come now to the Orchid section, one of the most interesting features of the Exhibition. In one house was a large exhibit from the firm of OTTO BEYRODT, of Berlin, excellent in quality and variety. In another part of the same house LOUIS VAN HOUTTE, of Ghent, exhibited stove plants and *Hippeastrums*. In another house M. PAUWELS showed a fine collection of Orchids, in which *Cymbidium Pauwelsii* made a conspicuous show. MESSRS. LAMBEAU and PEETERS also exhibited in this house, and the merit and value of their plants well sustained their high reputation. M. LAMBEAU showed many fine forms of *Odontoglossum*, among them a distinct, darkly blotched form which he has named *H. F. Eilers*; it bears flowers $4\frac{1}{2}$ inches in diameter. M. PEETERS also showed good, unnamed *Odontoglossums*. He included *Cattleya Julietta* in his exhibit, a rarity which is coveted by many Orchidists; and M. LAMBEAU had *Odontioda Beauté de St. Petersbourg*, also a favourite. In this latter exhibitor's collection was to be found *Cochlidia Noezliana* var. *Chanticleer*—a brilliant flower—and *Miltonia vexillaria* in many good forms, the best being *Memoria G. D. Owen*. Many good *Cattleyas* and bigeneric crosses were shown, but the heat told badly on the flowers. The long journey and the delay consequent on Customs formalities are a severe test for any plant, but the Orchids came through the ordeal wonderfully well considering all things.

Mention must be made of the hall built and furnished by MESSRS. EILER. It formed a tasteful and charming feature in the Exhibition. A pavilion had been erected for the accommodation of exhibits from the Russian provincial schools. The group from Warsaw was of exceptional interest and variety. In the outer hall an interesting exhibit was shown by the Russian Government of the processes by which the drifting of sand over the railway tracks was arrested. Models of the railway tracks were shown, with sand dunes on either side; and the plants used for binding the sand were shown in dried specimens, with seeds, accompanied by classified tables and full information.

The interest taken by English nurserymen in the Exhibition is not remarkable, only two representatives being here, while there are very many Germans, Danes, Swedes, Dutch, French, Belgians, and even Italians. This is a pity, as the Exhibition is really a good one, and reflects very great credit on all those responsible for its management. *James Whitton*.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MAY 14.—*Committee present*:—Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, J. Bamber, J. Cypher, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, W. J. Morgan, C. Parker, W. Shackleton, H. Thorp, Z. A. Ward, G. Weatherby, and H. Arthur (secretary).

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish), was awarded a Silver-gilt Medal, and R. ASHWORTH, Esq., Newchurch (gr. Mr. Gilden), a Silver Medal for groups.

AWARDS.

FIRST CLASS CERTIFICATE.

Miltonia vexillaria Memoria G. D. Owen, from R. ASHWORTH, Esq.

Odontoglossum Acroplane × *Exquisitum*, and *O. Jasper "Ashlands"* var., both from R. ASHWORTH, Esq.

O. Prometheus "Merl Dene" var., from A. J. OAKSHOTT, Esq.

ANNUAL MEETING.

At the annual meeting held on the same date Mr. R. Ashworth was re-appointed president and hon. treasurer. The Rev. J. Crombleholme was re-appointed chairman, Mr. Z. A. Ward, vice-chairman, Mr. H. Thorp, hon. auditor, and Mr. H. Arthur, secretary. The committee was also elected.

The prizes were presented to the successful exhibitors as follows:—

The President's Cup was won by R. ASHWORTH, Esq., who presented same to the Society for competition during the coming season.

Mr. J. J. Bolton's Gold Medal, to A. WARBURTON, Esq.; Gardener's Prize to Mr. A. DALGLEISH; and Mr. Bolton's Silver Medal, to R. ASHWORTH, Esq.; Gardener's Prize to Mr. GILDEN.

The Botanic Society of Manchester's Gold Medal was awarded to R. ASHWORTH, Esq.

The *Objet d'Art* presented by Messrs. Charlesworth and Co., to WM. THOMPSON, Esq., and the Gardeners' Prize to Mr. J. HOWES.

The "Cypher" Gold Medal was awarded to R. ASHWORTH, Esq., the "Davidson" Silver Trophy to R. ASHWORTH, Esq.; Gardener's Prize to Mr. W. GILDEN.

"Evans" Gold Medal, to WM. THOMPSON, Esq.; Gardener's Prize to Mr. J. HOWES.

Messrs. Sander and Sons' Prizes were awarded as follows:—1st, Mr. A. DALGLEISH; 2nd, Mr. W. GILDEN; 3rd, Mr. J. HOWES.

The Society's Medals were awarded as follows:—Gold Medal, to Z. A. WARD, Esq.; Silver-Gilt Medal, to Colonel J. RUTHERFORD; Bronze Medal, to the Rev. J. CROMBLEHOLME; and Gold Medal (Small Amateur's), to H. ARTHUR, Esq.

BATH AND WEST OF ENGLAND AGRICULTURAL.

MAY 23—JUNE 2.—Under the able stewardship of the Rev. A. J. Boscawen, who was assisted this year by Mr. V. T. Hill, the horticultural section of this show has grown to be an exhibition of considerable importance. The special tent allotted to horticultural exhibits has for many years been well filled, and this year an enlargement about half as long again was also well furnished with a very creditable display. The date of the show did not clash with the Chelsea Show this year, as has been the case in previous seasons, and this fact enabled the horticultural trade to be represented more fully than usual.

Sir J. T. D. LLEWELYN, Bart., the President of the Society, exhibited *Rhododendrons* and *Primulas*.

MESSRS. JAMES HARRIS AND SON, Blackpill, Swansea, showed *Rhododendrons*, shrubs, and specimens of *Viburnum plicatum*.

MESSRS. GEO. COOLING AND SONS, Bath, exhibited *Roses* and *Clematis*.

MESSRS. R. VEITCH AND SON, Exeter, contributed a fine stand of half-hardy shrubs and New Zealand plants, besides *Roses*, *Carnations* and *Rhododendrons*, *Abelia trifolia* and *A. floribunda*, *Edwardia grandiflora*, and *Olearia insignis* were among the tender shrubs, whilst a variety of *Saxifraga Cotyledon* which originated in the Rev. A. T. Boscawen's garden was conspicuous amongst the Alpines.

MESSRS. WM. CUTBUSH AND SON, Highgate, displayed *Carnations* and climbing and Dwarf *Polyantha* *Roses* in good form.

MESSRS. WALLACE AND CO., Colechester, had a large exhibit, including German *Iris*, *Lupins*, *Aquilegias* and *Hemerocallis*, *Eremurus* and *Habranthus*.

Messrs. PAUL AND SONS, Cheshunt, showed a fine exhibit of *Roses*.

MESSRS. GODFREY AND SON, Exmouth, exhibited a large bank of *Poppies* and *Pelargoniums*.

MESSRS. J. WATERER, SONS, AND CRISP, LTD., Bagshot, showed *Rhododendrons*, a plant of *Lady Cathcart* being particularly fine.

MESSRS. BLACKMORE AND LANGDON, Twerton Hill Nurseries, Bath, showed *Delphiniums*, par-

ticularly fine spikes of Statuaire Rude, Capri, and Moerheimii.

Messrs. A. A. WALTERS AND SON, Bath, exhibited climbing and Dwarf Polyantha Roses.

Messrs. JARMAN, Chard, showed Centaureas.

Mr. MAURICE PRICHARD, Christchurch, had a creditable exhibit of Alpines, including *Malvastrum hypomandarum*, *Mimulus radicans*, *Edrianthus pumiliorum* and *Stachys corsica*.

Messrs. DOBBIE AND Co.'s exhibit of Sweet Peas was much admired, particularly Dobbie's Orange—a fine colour.

Messrs. W. TRESEDER, LTD., Cardiff, showed *Pyrethrums* and *Dahlias*.

Messrs. BIDE AND SONS, Farnham, showed Sweet Peas.

Mr. H. N. ELLISON, West Bromwich, showed Ferns and Cacti.

Messrs. REAMSBOTTOM AND Co., Geashill, Ireland, showed St. Brigid Anemones and other flowers.

Messrs. F. F. W. EVANS, Llanishen, near Cardiff, showed herbaceous and Alpine plants.

Messrs. BAKERS, Wolverhampton, had a group of *Aquilegias*, with Alpines in front.

Mr. J. ANSOLDO (amateur), Sunny Bank, Mumbles, near Swansea, showed an interesting exhibit of *Primula amoena*, *P. pulverulenta*, *P. Cockburniana* and hybrids.

EDINBURGH BOTANICAL.

MAY 14.—Among the specimens shown at the May meeting of this society was a shrub forwarded by Mr. BELL of "The Woll," Hawick. A fruiting specimen had been sent to the Royal Botanic Garden, Edinburgh, last autumn by Mr. W. B. BOYD, with the suggestion that it was probably a hybrid between the Black Currant and the Gooseberry. Comparison in the Royal Botanic Garden Herbarium was, on the whole, in favour of Mr. BOYD's suggestion, but, in the absence of flowers, no definite opinion was arrived at. However, a photograph of the plant was sent to Professor Janczewski, the recognised authority on *Ribes*, but owing to indisposition he was not able to give the matter full attention. He, however, inclined to the belief that it resembled certain of the species of North America rather than a hybrid between the Black Currant and the Gooseberry. This view had already been taken by Mr. BENNET CLARK, a past President of the society, who dissented strongly from its being a hybrid, and considered it much more likely to be an exotic species established for many years near Hawick. In his belief, *Ribes divaricatum* from North-West America came very near to it.

Flowering specimens obtained this month both from Woll and from cuttings taken by Mr. BENNET CLARK, and grown at his garden at Newmills, Balerno, match exactly specimens of *R. divaricatum* in the Royal Botanic Garden, Edinburgh, and the figure No. 1,359 of the plant in the *Botanical Register* of the year 1830. It seems then that the name given to it, *Ribes wollense*, in a recent issue of the *Kew Bulletin* (1914, p. 49, with a plate of Mr. BOYD's photograph, where it is described as a new hybrid) will have to give place to the old specific name. After an interesting discussion, Mr. BOYD, who last year strongly favoured its being a hybrid, was understood to acquiesce in Mr. BENNET CLARK's determination.

Among the other plants recently exhibited at the society meetings, the following from the Royal Botanic Garden are of special interest:—

Ribes Henryi, Franch.—Male plants of this species were in good flower in March.

Androsace Delavayi, Franch.—A pretty species forming dense cushions and bearing numerous pink and sweetly scented flowers just above the foliage.

Rhododendron Hanceanum, Henry.—A pale yellow-flowered Chinese species which is very floriferous in the young state.

Primula Inayati, Duthie.—A North-West Himalayan plant of the *Nivalis* section.

Pernettya furcens, Klotzsch.—A hardy Chilean shrub suitable for the rockery.

The above were all in flower in March.

Rhododendron fastigiatum, Franch.—A dwarf plant of a few inches in height, with small foliage and bright purple flowers about half-an-inch in diameter.

Rhododendron lutescens, Franch.—A yellow-flowered species of shrub habit, with bronzy foliage, also from China.

Rhododendron Davidsonianum, Rehder and Wilson.

Rhododendron polylepis, Franch.

Roettlera Forrestii, Diels.—An interesting Chinese Gesnerad of neat habit, with hairy foliage and yellow flowers.

Primula redolens, Balf. fil.—A new species of the section *Suffruticosae*, closely allied to *P. Forrestii*, Balf. fil. This was raised at the Royal Botanic Garden, Edinburgh, from seed presented by Mr. A. K. Bulley, collected by F. Kingdon Ward on the borders of China and Tibet.

These were all in flower in April.

SOMERSET COUNTY AGRICULTURAL.

MAY 13, 14, 15.—The annual exhibition of this Agricultural Association, which was held at Weston-super-Mare on the foregoing dates, included a section for horticulture, and the floral exhibits were the best in the history of the society. In the class for a group of miscellaneous plants, arranged in a space measuring 75 feet, the 1st prize was won by Messrs. BROOKS, of Weston-super-Mare; 2nd, Messrs. GEORGE COOLING AND SONS, Bath. Mr. C. J. ELLIS, Weston-super-Mare, exhibited the best rock garden, and he also excelled in the class for a collection of Carnations. Trade exhibits were shown by Messrs. R. VEITCH AND SON, Exeter; Mr. W. J. GODFREY, Exmouth; Mr. C. J. ELLIS, Weston-super-Mare; Mr. A. F. DUTTON, Ivor; Messrs. G. COOLING AND SONS, Bath; and Messrs. YOUNG AND Co., Cheltenham.

Obituary.

JAMES UNDERWOOD.—We regret to announce the death of Mr. James Underwood on May 25, aged 64 years. Mr. Underwood was head gardener at Enderby Hall, Leicestershire, the residence of the late Captain Drummond. Prior thereto he was gardener at Delapre Abbey, Northampton, and while in that locality was a most successful exhibitor at the flower shows. The funeral took place at Enderby on the 28th ult.

BRIAN P. CRITCHELL.—Mr. Brian P. Critchell, described in *The American Florist* as one of the oldest and best-known florists of Cincinnati and the surrounding section of Ohio, died at Avondale, U.S.A., on May 11, in his 72nd year. He was born near Liverpool, but removed to Rochester, N.Y., with his parents when four years old. For a period he was Superintendent of Parks at Cincinnati.

JAMES F. SLIMON.—*The American Florist* also records the death of Mr. James F. Slimon, a native of Scotland, who for more than twenty years was a well-known member of the seed trade of New York.

JULIUS WHITE.—The death on May 10 of Mr. Julius White is recorded in *The Florists' Exchange of America*. He was born in Somerset, England, in 1850, and settled in America when quite young, learning the trade of a carpenter. Later in life he established a florist's business, which proved a successful undertaking.

ENQUIRY.

CAN any reader inform me if Phlox Van Houttei is still in cultivation? It was a favourite garden plant fifty years ago, was very pretty, quite hardy, but not long-lived. The plant is figured in *Bot. Reg.* XXIX. 5. E.

SCHEDULES RECEIVED.

Tunbridge Wells and South-Eastern Counties Agricultural Society.—Annual show, including horticultural section, will be held on July 22 and 23, 1914. Secretary, T. E. Collins, 73, High Street, Tunbridge Wells.

Sherborne Floral Fete, to be held on Thursday, June 25, in the Old Castle Grounds, Sherborne. Secretary, Mr. G. M. Ingram, The Abbey Close, Sherborne.

Saltire, Shipley and District Rose Society's twelfth annual exhibition, to be held in Saltire Park, on July 14 and 15.

MARKETS.

COVENT GARDEN, June 5.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

REMARKS.—Last Friday and Saturday were the busiest days in the flower market since Easter. White and scarlet flowers were mostly in demand and prices rose considerably on the Friday. Scarlet Carnations advanced in value from 2s. to 3s. before the close of the market, whilst the stocks of best quality scarlet Pelargoniums (Geranium) were all bought immediately the market opened. White Carnations, double white Narcissus, white Pyrethrum, white Paeonies and Lilium Harriisii were other subjects that met with a ready sale. Prices continued firm until the close of the market on Saturday. The salesmen found no difficulty in clearing their stocks of single coloured Pyrethrum and all trises. High prices were realised for white Gladiolus The Bride, and the coloured varieties Ne Plus Ultra, Brilliant and Akermanii of a salmon colour. Double white Narcissus is now practically finished, the supplies coming from Scotland. Pyrethrums appear to be more plentiful than ever. Blue Cornflower, Iceland Poppies and Sweet Peas are being sent in greater quantities, and prices for these flowers are much lower. A few boxes of white Pinks (Mrs. Sinkins) are now on the market. The Rose trade is very

quiet and there is nothing exceptional in the quality of those offered for sale. Blooms of the varieties Liberty and Frau Karl Druschki with long stalks are the most valuable. Lily-of-the-Valley is not so plentiful as hitherto; spikes grown out-of-doors do not find a ready sale, possibly on account of their stems being short.

REMARKS.—Crassulas in white, pink and red varieties are the latest addition in this department. White Marguerites in 48 pots are seen in fine condition; there are also excellent plants of the double variety, Mrs. F. Sanders. There is a good display of other flowering plants, and business continues very brisk.

REMARKS.—About 80,000 packages of Grapes, Apples and Pears have arrived during this week from Australia. Forced Strawberries are plentiful and of good quality. Large quantities of outdoor Strawberries, packed in punnets and skips, are received daily from Southampton, Devon and Cornwall, and good samples are now on sale. Larger consignments of Muscat of Alexandria and Black Hamburg Grapes of better colour than of late arrive daily. Continental Apricots and Cherries and English Gooseberries are very plentiful.—E. H. R., Covent Garden, June 3, 1914.

REMARKS.—Asparagus, both English and Continental produce, is becoming scarce, whilst Peas and Broad Beans from Kent and the West of England are fairly plentiful. Of the commoner vegetables Cauliflower, Cabbage, Onions and Horseradish are scarce, but other kinds are a good supply.—E. H. R., Covent Garden, June 3, 1914.

GARDENING APPOINTMENTS.

- Mr. Edward Batchelor, 1st Foreman at Sunningdale Park, as Superintendent of the Gardens at the Hospital for the Insane, North Battleford, Saskatchewan, Canada. [Thanks for 2s. for R.G.O.F. Box.—E.H.]
- Mr. E. W. Fuller, for more than 2 years Foreman in the Gardens at Henham Hall, Wangford, Suffolk, and previously at Heveningham Hall, Yoxford, Suffolk, and Paddockhurst, Crawley, Sussex, as Gardener to JAMES BUCHANAN, Esq., Lavington Park, Tetworth, Sussex.
- Mr. Lewis Williams, for more than 4 years at Llanover Court, Abergavenny, as Gardener to JOHN WOOD, M.P., Hengrave Hall, Bury St. Edmunds.
- Mr. T. P. Brown, for the past 7 years Gardener to Colonel H. F. BOWLES, Forty Hall, Enfield, as Gardener to Mrs. MONTGOMERY-PATERSON, Eastley House, Thorpe, Surrey.
- Mr. A. Williams, for the past 2½ years at Hill Crest, Evesham, as Gardener to the Misses WEISS, Chambers Court, near Tewkesbury.
- Mr. Joseph Smith, for the past 3 years Gardener for Mrs. LAUD, at Delover, Birkenhead, as Gardener to Sir THOMAS ROYDON, Bart., Frankby Hall, Frankby, Birkenhead, Cheshire.
- Mr. W. J. Harris, for 4 years Gardener to G. S. LOVELL, Esq., Bromley, as Gardener to G. H. NEAME, Esq., Godden Green, near Sevenoaks.
- Mr. Thos. E. Parker, previously Inside Foreman to the Right Hon. Lord DEVONPORT, K.G., Wittington Hall Gardens, Marlow, Buckinghamshire, and Peckforton Castle, Cheshire, as Gardener to W. HERBERT PHILIPPI, Esq., Craigmellan, Gilberton, Adelaide, South Australia. [Thanks for 2s. for R.G.O.F. box.]—E.H.]

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending May 30, is furnished from the Meteorological Office:—

REMARKS ON WIND AND WEATHER.

June 2, 1914.
Early in the week, when a depression had passed eastward over these islands, the wind became northerly, with rain in many places, temperature decreased very decidedly, and a little later during clear skies at night and an anticyclonic distribution of pressure, frost was experienced over a large area, both in Great Britain and Ireland. In several localities the frost was sufficiently severe to cause much injury to vegetation. Later in the period the wind became more variable, and finally shifted to the south-west or west, while temperature became higher during the day and less low at night. Rain was experienced in the western and northern districts with the change of wind direction and the return to cyclonic from anticyclonic conditions, but the falls were mostly slight or moderate.

THE WEATHER IN WEST HERTS.

Week ending June 3, 1914.
Another Dry Week, and the Third in Succession.—The past week was one of about average temperature. The one exception was the first night, when the exposed thermometer registered 6° of frost. The ground is at the present time at about an average temperature at 2 feet deep, and a degree warmer than is seasonable at 1 foot deep. Rain fell on four days, but to the total depth of less than a quarter of an inch. During the previous fortnight there had been virtually no rain at all. There has been no percolation of rain-water through either of the soil gauges for three weeks. The sun shone on an average for 4½ hours a day, which is 1½ hours a day short of the usual duration at the same period of the year. Calms and light airs alone prevailed during the week, the direction of these light airs being principally some northerly point of the compass. The mean amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by 8 per cent.

THE SPRING.

Very Warm and Sunny, and Rather Wet.—This proved, with one exception, the warmest spring for eighteen years. March and April were both warm months, but in May the mean temperature was about seasonable. The total rainfall for the quarter exceeded the average by an inch, March being remarkably wet, whereas in both April and May the rainfall was deficient. This proved the sunniest spring with one exception experienced here for twenty-one years. March was a dull month, whereas April was exceptionally sunny, and May had about an average record of sunshine.—E. M. Berkhamsted, June 3, 1914.

ABNORMAL WALLFLOWERS: F. F. Taylor. The specimens of Wallflower are bearing abnormal flowers. The petals are suppressed and the stamens are represented only by rudiments, so that the flower contains nothing but yellow sepals and green pistil. This abnormality is not attributable to defective cultivation, but is an inherited character inherent in the strain. Recent experiments made by Mr. Chittenden at Wisley, and reported in *Gard. Chron.*, May 9, 1914, p. 322, show that this "virescence" behaves in breeding as a recessive character: that is to say, if the pistil of the abnormal flower be pollinated with pollen from a normal flower, no sign of the abnormality is to be observed in the offspring; but if the offspring be self-fertilised, it gives rise to plants of which three-fourths are normal and one-fourth abnormal. The interpretation of this result is as follows:—The abnormality is due to the absence from the germ-cells of a factor which, present in normal plants, causes the petals and stamens to develop. When a normal plant is fertilised, both its male and female germ-cells contain this petal-producing factor, and hence the embryo cell formed by the fusion of the germ-cells contains two doses of this factor, and presently, when the embryo has produced a flowering plant, the germ-cells contained in the flower have all this factor. But when an abnormal is mated with a normal flower, the embryo cell contains only one "dose" of the petal-producing factor. This dose is, however, sufficient to cause the flower to develop normally. But of the germ-cells of the apparently normal flowers produced by crossing normal and abnormal some contain the factor in question and some do not. When the male and female germ-cells mate there are the following possibilities:—Normal male germ-cell meets normal female germ-cell; normal male germ-cell meets abnormal female germ-cell; abnormal male germ-cell meets normal female germ-cell; abnormal male germ-cell meets abnormal female germ-cell; and in the last case the offspring will exhibit the deformity in question.

CAULIFLOWERS FAILING: J. K. Your plants are attacked by a worm known as *Fridericia bisetosa*. The ground on which the Cauliflowers were growing should be dressed with gas-lime; or quicklime will do if the former be not available.

CUCUMBER FRUITS NOT SETTING: W. H. J. Your Cucumbers are not diseased; the reason for their shrivelling is not apparent.

EMPLOYMENT AT KEW AND WISLEY: Learner. As you have not been trained as a gardener, and have very limited experience, you cannot obtain a post on the gardening staff in the

Royal Botanic Gardens, Kew, or at the Royal Horticultural Gardens, Wisley. The R.H.S. School of Horticulture admits a limited number of young men to study the principles and operations of horticulture in their gardens at Wisley, but applicants must be between sixteen and twenty-two years of age.

FLOWER BORDER FOR SPRING AND AUTUMN EFFECT: *A Dorset Gardener.* A border of the width you describe might very well include a few shrubs, such as *Buddleia variabilis* magnifica, the branches to be cut to the ground annually; *Spartium junecum*, *Fuchsia Riccartoni*, cut over annually this plant forms a lovely, straight-stemmed mass of bloom; *Romneya Coulteri*, which also should be cut down annually; *Common Rue*, *Lavender* in good-sized groups, *Caryopteris Mastacanthus*, cut over; *Spiraea Anthony Waterer*, pruned hard in March; and *Desmodium penduliflorum*, which should be pruned to the ground level. A few late-flowering *Clematis*, trained to poles, *Prunus Pissartii*, the shoots cut over in spring, *Rose Fellenberg* and tree *Paeonies* are also suitable. Of hardy herbaceous plants *Bocconia cordata*, *B. microphylla*, *Spiraea kamschatica*; *Hollyhocks*, especially single varieties allowed to grow into large, many-spiked clumps; *Phlox paniculata alba*, *Helonium autumnale* vars., *Delianthus* Miss Mellish, *Senecio tanguticus*, as beautiful in seed as in flower; *Echinops Ritro*, *Anthemis tinctoria* vars., cut over in summer; *Aconitum Wilsonii*, *Achillea Ptarmica* Perry's variety and *The Pearl*, *Asters Climax*, *W. Bowman*, *Jessie Croome*, *Aeris* and *A. linoxyris*; *Anemone japonica* Profusion and *Géant des Blancs*; *Montbretias Vulcan*, *King Edmund*, *Hereward* and others; *Gladiolus* planted in May, *Fennels* (*Feniculum*), *Stalice latifolia*; *Lobelias* of the tall section, *Pyrethrum uliginosum*, *Linaria Pancicii*, *Eryngium Oliverianum*, *Antholyza paniculata*, *Anchusas Dropmore* and *Opal*; *Salvia patens*, *Nepeta Mussinii*, *Lilium tigrinum*, *L. Fortunei*, *L. speciosum* vars., *Colchicum spectabile album*, *Perpetual Carnations*, *Delphiniums* from seed, and *Lupinus polyphyllus*, also from seed the same spring; *Pentstemon Dav Dream*. To fill odd spots *Stock-flowered Larkspurs* and tall *Snappedragons* would be very useful. Some of the above-named plants are evergreen, and would need no substitute for spring, and a large number to yield their best and to meet the requirements of space for a spring bloom would need to be divided annually and replanted as small plants. It is, on the whole, the most satisfactory method of growing these well. For spring do not rely on *Belladonna Lilies* succeeding when mixed with another plant, for these make their growth in spring, and to flower satisfactorily must have plenty of space. Some seeds of a dwarf annual to cover the bare spaces after foliage dies is all you could wisely attempt. Your suggestion to plant *Crown Imperials* is a good one. You can scarcely use too many. They are glorious in clumps, the corms set one foot apart, and no succeeding plants harm nor are harmed by them. It is not essential to study the autumnal plants when arranging for an earlier display. You may introduce *Tulips*, splashes of *Daffodils*, *Blue-bells*, *Iris reticulata*, *Snowdrops*, *Crocuses*, *Scilla praecox*, *S. taurica* and *S. bifolia alba*; *Muscari botryoides album*, but not the type which becomes a weed; *Puschkinia scilloides*, *Chionodoxa* and *Fritillaries*, and there is no reason why advantage should not be taken of *Myosotis*, *Wallflowers* and such-like plants may be employed as temporary means of adding glow or charm to the border. You would find annual deep digging or trenching of infinite value, which would, of course, necessitate annual transplanting. Consolidate the soil by trampling when moderately dry, and if you keep poultry apply a few dressings of their manure to the surface in the course of the growing season. Superphosphate of lime is also of value, or any good commercial fertilisers, whilst mulches of soil applied after rain will afford a remarkable degree of benefit. After all, you must make up your mind to feel your own way, for everyone who succeeds has

that road to travel however well he or she may have been equipped at the start.

GARDENING EMPLOYMENT AT WISLEY.—In addition to the students there is a paid gardening staff at the R.H.S. Gardens, Wisley, as in any other establishment; but we cannot say at the present time whether there are vacancies. The journeyman gardeners receive a remuneration, and are provided with an up-to-date botany. Write to the superintendent, who will furnish you with all particulars.

INSECTS: *Mrs. T.* The grubs found in the Ivy are the larvae of a species of weevil. Weevils are beetles with a long, pointed snout, and the larvae are cream coloured or yellow, legless; they have strong jaws, and soon after hatching begin to inflict damage by voraciously feeding on the food immediately within their reach. The perfect insects feed at night and often escape detection by the gardener, but they may be trapped by slices of Carrot or Potato, and should be looked for at night by the aid of a lantern. There are several species, and they attack various species of plants; sometimes they attack the roots and at other times the leaves. The larvae of one species may frequently be found in pots containing Ferns and allied plants. In such cases it is difficult to apply any insecticide that will kill the grubs that is not also strong enough to injure the roots, but by turning the roots out of the pots it is often possible to discover the grubs and so rid the plants of the pest, provided traps are set for the perfect insects. Vaporite has also been found beneficial. The appearance of the grub and perfect insect is shown in the illustration (fig. 188).

MUSHROOMS: *F. W. K.* The failure may be due to many causes, but as far as one is able to

FIG. 188.—BLACK AND CLAY COLOURED WEEVILS.

judge from the specimen of the bed sent the material at some time or another has become too wet. The sample of spawn is excellent. Though *Mushrooms* ought to have appeared before now, it is just possible you may yet get a partial crop.

NAMES OF PLANTS: *Bucks.* 1, Send when in flower; 2, *Tilia platyphyllos asplenifolia*.—*P. C.*, *Leicester.* *Manna Ash* (*Fraxinus Ornus*).—*N. F. P.* *Syringa Josikaea*.—*A. T. H.* 1, *Cladrastis tinctoria*; 2, *Sophora japonica*; 3, *Pyrus nigra*; 4, *Cotoneaster Lindleyi*; 5, *Cotoneaster Henryana*; 6, *Rubus bambusarum*.—*L. S. G.* 1, *Aesculus carnea* var. *Briotii*; 2, *A. flava* var. *sanguinea*; 3, *A. flava*.—*H. V.* 1, *Tilia platyphyllos* var. *asplenifolia*; 2, *Pyrus Terminalis*; *Pyrus Aria* var. *majestica*; woolly beneath leaf, no number.—*A. R.* *Roses*: 1, *Persian Yellow Briar*; 2, *Yellow Banksian*.—*S. E. A. T.* 1, *Phlox Stellaria lilacina*; 2, *Helianthemum vulgare cupreum*; 3, *Alyssum saxatile*; 4, *Saxifraga trifurcata*; 5, *S. Cotyledon*; 6, *Sedum rupestre*.

NECTARINES EATEN: *J. P.* The skin of your Nectarines has been eaten by some insect, probably a cockroach. Place a few slices of Potato about before leaving the house, and come back after dark to look for the insects, which will be attracted by the smell of the Potato, and can be easily killed.

PEACH LEAVES INJURED: *Distressed.* There is no disease present in your Peaches, and from the appearance of the leaves it is evident that, as you suspect, they have been injured by the fumes from the paint. The leaves already damaged can be removed, and further injury prevented by providing plenty of ventilation.

PEARS INFESTED WITH MAGGOTS: *F. R. S.* The maggots in your Pears are those of the "Pear midge." The only thing you can do now is to prevent a repetition of the attack next year by plucking off and burning all infested fruits.

PROPAGATING PIT: *H. S.* Your propagating pit is much too deep. Raise the bed to within 18 inches of the roof-glass. Slabs placed side by side and resting on supports formed of bricks or other material would answer the purpose. Cover the slabs with chinkers or brick-rubble with sifted coal ashes on top to the thickness of 5 or 6 inches together to form a level, well-drained bed to stand the cutting-pots and cutting-boxes on. Raise the flow, and return 4-inch pipes to the level of the bed thus formed—that is, to rest on the bed one on either side close up to the walls. Have valves put in the flow, and return pipes, at the point where they enter the propagating pit to enable you to control and regulate the heat in the pipes. Cuttings inserted in the ordinary way in pots and shallow boxes filled with light mould and surfaced with sand, watered through a rose can, kept close, with a moist atmosphere and shaded from sunshine during the heat of the day, will soon root.

RESIDUE FROM A BURNT HAYRICK: *W. F. G.* The ash from a burnt hayrick contains potash, silica, soda, traces of lime and a few other elements. The manurial value is found principally in the potash, which would benefit nearly all crops, but we do not advise its use for lawns. As the potash is in the form of the oxide, it would be rather caustic in its action, and should therefore not be applied so as to come into direct contact with any part of the plant. If, however, you mix the ash with dry soil and apply it a little and often as a dressing, it will supply valuable plant food.

SCREEN FOR A CLIMBING ROSE: *Rosa.* As you do not wish to plant Ivy, and there are no other fast-growing evergreen climbers that would suit your purpose, you might plant a fast-growing *Wichuraiana* Rose, such as *Edmond Proust*. This variety is almost evergreen, and would not only serve to break the wind, but would also be a beautiful object in itself.

VINE DISEASED: *W. P.* Black rot is present in the specimen sent for examination. It is too late to apply any remedies this season, but next year you should spray when the leaves are half grown, with *Bordeaux* mixture at half strength. The operation should be repeated when the berries have set.

VINE SHOOTS AFFECTED: *J. M. T.* There is no disease present in your vines, and their condition must be due to some error in cultivation.—*Anxious.* See reply to *J. M. T.*

WASP'S NEST: *S. R. Foster.* "The very first commencement of a wasp's nest" you sent us was scarcely recognisable when the box was opened, owing to your having included a lump of the clay bank in which, we presume, it was found. Had you sent the nest alone packed lightly in cotton-wool it would not have arrived in such unrecognisable fragments. From the colour of the paper it appears to be a nest of the German wasp (preferably called the large common wasp), *Vespa germanica*; but we do not understand why there were two queens in the nest. Why did you not send them with it in accordance with our recommendation (p. 308, May 2) so that the matter could have been definitely settled? We incline to the belief that the two wasps were either the queen and a worker, or two workers, as it is practically impossible for there to be two queens in so small a nest so very early in the year. On the other hand, we have not yet seen any workers about, and queens are still flying; if any workers are about they must be the offspring of queens which started to nest before May 1.

AMONG THE ROSES.

HERE is no doubt that Roses well repay the time spent on the many little attentions which those who are not Rosarians might be excused for describing as "pottering about over the Roses." It is indeed partly on this account that the Rose is pre-eminently an amateur's flower.

Time and again the National Rose Society has been asked to institute classes at their exhibitions confined to amateurs who cultivate their own Roses, but the answer has always been that experience has proved that such amateurs can successfully hold their own in competition with those who leave the cultivation of their plants to the gardener. Now this is no reflection upon the capacity or ability of the professional gardener, but merely means that he has many things under his care besides the Roses, and cannot spare the time for those numerous and perhaps rather leisurely little attentions that the amateur can bestow upon his plants.

Perhaps there is no time of the year when this special attention is more necessary than the end of May and the early part of June. The more burdensome and monotonous requirements of cultivation, such as regular hoeing and manure watering, the amateur may very likely leave to his professional assistant, but there are many that he will doubtless deal with himself.

First there is the regular search for caterpillars and the destruction of green fly whenever it makes its appearance. For the caterpillars and slug-worms each bush must be regularly and carefully examined, and where the foliage or buds have been attacked the devastator must be sought for and slain. Wherever there is a curled leaf the rule is simple, pinch first and examine afterwards; if the enemy was at home so much the better, if not he must be sought for on some other part of the shoot, or another near thereto, until he is found and destroyed. Green fly can also be attacked with the finger and thumb, but if there are more than a very few this soon becomes an irksome and messy business, and syringing is preferable.

For my own use in this connection I keep two kinds of sprayers, one holding a gallon or more, with a shoulder strap, for extensive operations on pillars and climbing Roses, and the other, with a much finer spray for more careful work, which holds rather less than four pints of liquid. The green fly will generally be first noticed on the buds and the tops of the young shoots, but if these alone are sprayed the pests will usually have come back again next day, for many have been hiding underneath the young leaves towards the top of the shoots, and have thus escaped the spraying fluid. The best way to go to work is, while holding the sprayer in one hand, to gather the top of the infested shoot in the other and gradually turn over each leaf as the spray is directed on the shoot, so that every part of the shoot and leaf is well searched with the spray. For this reason I prefer to use some non-poisonous spraying fluid, such as soft soap and quassia, Cyllin soft soap, or Abol, which, in the proportions in which they are mixed with water for use, will not injure the fingers.

While going over the shoots in this way it is a good plan to examine carefully the buds and disbud where it is desirable, bearing in mind that it is best not to do all the disbudding intended at once, but, rather, in several operations. Not only is this better for the bud finally selected, by concentrating the resources of the plant gradually upon it rather than overwhelming it with a sudden influx of sap, but it gives us greater scope for selection and something to fall back upon in case of accidental injury.

Another important matter that will receive careful and sometimes anxious consideration where fine flowers of exhibition varieties are wanted, will be the number of shoots to be left on each plant. Where the numbers of young growths are numerous any barren ones will be removed at once, whether the barrenness has arisen naturally or as the result of injury to the flower-bud. These barren shoots may receive more consideration where the number of young growths on the plant is not excessive, or where there is no special object in restricting the number of growths. If, as often happens, the barren shoot is the end one, and if there is any suspicion of injury or want of vigour in the old stem from which it springs, it is generally best to remove it,

cutting back the old stem to the next effective shoot. If there is no suspicion of want of vigour, as where the bud has been merely destroyed by a grub or other mechanical injury, it is often best to shorten it somewhat, cutting back to a leaf pointing outwards, at the axil of which a fresh growth will soon form.

A form of pest that has become troublesome of recent years is the leaf-curling saw fly. This fly is quite small; much slighter than the lesser house fly. It lays its eggs on the under edge of the leaf blade, and then works away at the top, causing the leaf to curl inwards towards the midrib; the egg is thus protected by the curled leaf, which slowly withers, and a little whitish grub hatches out in time. It is obviously desirable, therefore, to pick off and burn the affected leaves, which are of little further use to the plant, and it is also well to search for and destroy the flies themselves, which on a fine sunny morning can often be caught when at work on the leaves.

Besides the search for pests a watchful eye must be kept on the plants for the first indications of fungous disease. Where only a few leaves are attacked they may be picked off and burnt; the spot will be remembered, and an assiduous watch kept for any spread of the disease. If the disease is noticed on many leaves some appropriate form of spray should be at once applied to prevent any further spreading of the disease.

The removal of briar suckers alike from maiden and around established plants must always receive early attention. When these proceed from or near to the stock it is sufficient to pull them off, but where they proceed from an underground shoot and appear some distance from the parent plant, as often occurs in old standards, it is best to take a little extra trouble and pursue the underground runner to its source, and remove it cleanly. This, though it takes longer than just pulling them up, will save time later on.

Plants that have come badly through the winter, and newly planted Roses must also be carefully watched. A really good soaking of water to such a plant at this time of the year will often give just that additional encouragement that will make all the difference to the subsequent life of the plant. But here, too, judgment is required. A Rose that has suffered so severely that it is unlikely to survive long, or does not respond to the cold water cure, is best pulled up and got rid of forthwith to prevent it becoming a starting-point for disease, to which it is sure to fall a prey sooner or later. If the invalid is at all badly affected by cucumber fungus it is generally best to remove the plant at once, unless the whole of the fungus-affected part can be cut away, leaving good young shoots developing beneath it from sound wood. The young growths proceeding from a stem badly attacked by fungus are quite useless; they may maintain some feeble existence till July, but will produce no flowers of any value and usually wither and die before the summer is out.

If the Roses are sufficiently near to

gether (18 inches from plant to plant is a convenient distance for the majority of bed and border varieties) the removal of a single plant will scarcely be noticed. The Rose is not a symmetrical plant, and the growth of the neighbouring bushes will help to fill the gap as the summer advances. If, however, the gap is thought unsightly, plants in pots should be procured and put into the vacant places. *White Rose*.

ORCHID NOTES AND CLEANINGS.

AERIDES CRASSIFOLIUM.

A FINE inflorescence, consisting of a raceme over a foot in length and bearing twenty handsome flowers, each about 2 inches across, was sent by Mr. C. Wright, gardener to the Hon. N. Charles Rothschild, Ashton Wold, Oundle. The flowers are wax-like in substance and of a bright rose-purple colour, lighter at the bases of the segments, and with a white column. The species is of the *Aerides falcatum* section, but a dwarf grower, with thick, dark-green leaves. The specimen sent is of a very fine type, imported from a new locality by Messrs. Sander and Sons. It is the largest-flowered of the genus. It was originally imported from Moulmein by Messrs. Stuart Low and Co. in 1864, and described by the late Professor Reichenbach in the *Gardeners' Chronicle*, Vol. VII. (1877), p. 590. A full-size illustration is given in Vol. VIII., p. 493.

HYBRID ORCHIDS.

(Continued from p. 294.)

Hybrid.	Parentage.	Exhibitor.
Brasso-Cattleya Irene	B.-C. Digbyano-Warneri x C. Mossiae	J. and A. McBean.
Brasso-Cattleya Pervenusta	B. Digbyana x C. Fabia	Sander and Sons.
Brasso-Cattleya Rex	B. Digbyana x C. Rex	W. P. Burkinshaw, Esq.
Brasso-Cattleya Shilliana	B.-C. Digbyano-Mossiae x C. Mossiae	Armstrong and Brown.
Brasso-Laelia Mme. Irene Mavrocordato	B. Digbyana x L. Iona nigrescens	J. Gurney Fowler, Esq., and Messrs. Charlesworth.
Brasso-Laelio-Cattleya Albatross	B.-L. Digbyano-purpurata x C. Mossiae Wageneri	Flory and Black.
Brasso-Laelio-Cattleya Eudymion	B.-L. Digbyano-purpurata x C. Warneri	Charlesworth and Co.
Brasso-Laelio-Cattleya Everest	B.-C. Mrs. J. Leemann x L.-C. Canhamiana	Sander and Sons.
Brasso-Laelio-Cattleya Prince of Wales	L.-C. Dominiana x B.-C. Digbyano-Mossiae	Armstrong and Brown.
Cattleya Arestor	Nestor x labiata	Charlesworth and Co.
Cattleya Magali Sander	Dusseldorferi Undine x Mossiae Wageneri	Sander and Sons.
Cattleya R. Prove	intermedia alba x Susanne Hye de Cromi	Sander and Sons.
Cattleya Sibyl	aurea x iridescens	Hassall and Co.
Cymbidium Sappho	Lowianum x P. Ansonii	H. T. Pitt, Esq.
Cymbidium Venus	insigne x Holfordianum	Stuart Low and Co.
Cypripedium Julius	Rothschilbium x Lowii	Sander and Sons.
Cypripedium Susanna	glaucophyllum x Fairrieianum	Armstrong and Brown.
Laelio-Cattleya Anaconda	L.-C. Pallas x C. Dowiana Rosita	Baron Bruno Schroder.
Laelio-Cattleya Bellata	L.-C. Bella x L. purpurata	Flory and Black.
Laelio-Cattleya Corsair	L.-C. blechleyensis x L.-C. linnimosa Rosita	Mrs. Bischoffshelm.
Laelio-Cattleya Decata	L.-C. Decia x L. purpurata	Flory and Black.
Laelio-Cattleya Domos	L.-C. Dominiana x C. Mossiae	Stuart Low and Co.
Laelio-Cattleya Dryad	L.-C. Martinetii x C. Schroderae	Sander and Sons.
Laelio-Cattleya Galety	L.-C. Marriottiana x C. Mendelii	Sander and Sons.
Laelio-Cattleya Gold Star	L.-C. Ariel x C. Mendelii	Sander and Sons.
Laelio-Cattleya Joy Sander	L.-C. luminosa x C. Schroderae	Sander and Sons.
Laelio-Cattleya Medina Excelsior	L.-C. Canhamiana alba x C. Mrs. Myra Peeters	Flory and Black.
Laelio-Cattleya Sunstar	L.-C. Andromela x L.-C. Myra	Charlesworth and Co.
Laelio-Cattleya Sylph	L.-C. Hippolyta x C. Mossiae	Sander and Sons.
Miltonia Hyeana Adonis	veixillaria Memoria G. D. Owen x Bieniana rosea	M. Chas. Vuysteke.
Miltonia Isabel Sander	Roezlii x Hyeana	Sander and Sons.
Miltonia J. Gurney Fowler	veixillaria Mem. G. D. Owen x unknown	Armstrong and Brown.
Miltonia Miss Louisa Fowler	veixillaria Mem. G. D. Owen x unknown	Armstrong and Brown.
Odontioda beuchense	Odm. Rolfeae x C. Noezliana	Armstrong and Brown.
Odontioda delicata (Picardie)	Oda. St. Fuscien x Odm. ardentissimum	Sander and Sons.
Odontioda Leda	Odm. Rio Tinto x C. Noezliana	Sander and Sons.
Odontioda Leonatus	Odm. Thompsonianum x C. Noezliana	Sander and Sons.
*Odontioda oakwoodensis Fowler's Var.	Oda. Bradshawiae x Odm. percutum	J. Gurney Fowler, Esq.
Odontioda Phyllis	Oda. Bradshawiae x Odm. Lambeanum	G. W. Bird, Esq.
Odontioda Prince de Galles	Oda. Vuystekeae x Odm. Mirum	M. Chas. Vuysteke.
Odontioda Rosalie	Odm. Thwaitesii x C. Noezliana	R. G. Thwaites, Esq.
Odontioda Rubens	Oda. Charlesworthii x Odm. eximium	J. Gurney Fowler, Esq.
Odontoglossum Albion	Rossii x percutum	Sander and Sons.
Odontoglossum Bellamina	bellatulum x ardentissimum	De B. Crawshaw, Esq.
Odontoglossum Fortuna	Arlequin x Harryanum	Sander and Sons.
Odontoglossum Helicon	ardentissimum x Royal Monarch	Sander and Sons.
Odontoglossum Iconium	cirrhosum x Fascinator	Sander and Sons.
Odontoglossum Irene	Pescatorei x Vulcan	Sander and Sons.
Odontoglossum Iris	Pletcherianum x Lawrenceanum	Sander and Sons.
Odontoglossum Isidorus	cirrhosum x Rio Tinto	Sander and Sons.
Odontoglossum Jucundum	crispum x MacNabianum	Sander and Sons.
Odontoglossum Julius	Royal Monarch x Vulcan	Sander and Sons.
Odontoglossum Mendax	Kegejani (polyxanthum) x Ossulstonii	C. J. Lucas, Esq.
Odontoglossum Milo	Adrianae x Wilckeianum	Sander and Sons.
Odontoglossum nebulum	nebulum x aspersum	W. Thompson, Esq.
Odontoglossum Thwaitesii	ardentissimum x Harryanum	R. G. Thwaites, Esq.
Odontonia Roger Sander	Odm. percutum x M. Warszewiczii	Sander and Sons.
Oncidioda Mauricei	O. tigrinum x C. vulcanica	M. H. Graire.
Sophro-Laelio-Cattleya Delia	S.-C. Cleopatra x L.-C. Gottoiana	Charlesworth and Co.
Sophro-Laelio-Cattleya Dorila	S.-C. Doris x L. pumila	R. G. Thwaites, Esq., and E. H. Davidson and Co.
Sophro-Laelio-Cattleya Electra	S.-L. heatonensis x C. labiata	Charlesworth and Co.
Sophro-Laelio-Cattleya Hebe	S.-L. Gratrixiae x L.-C. Haroldiana	Charlesworth and Co.
Sophro-Laelio-Cattleya Lotis	S.-L. heatonensis x C. Harrisoniana	Charlesworth and Co.

* Odontioda Fowleriana (see report of the Chelsea Show) is a form of Odontioda oakwoodensis, *Gardeners' Chronicle* hybrid list, November 29, 1913, p. 375.

COELOGYNE ELATA.

A PSEUDO-BULB and inflorescence of this large-growing Coeogyne was imported by the Hon. N. Charles Rothschild from Borneo. This is a new locality for the species, its previous recorded habitats being in various parts of Northern India. The Bornean plant seems identical with the Indian type, its large pseudo-bulbs having broad, stalked leaves. The inflorescence, a foot or so in length, proceeds from the apex of the bulb. The upper part of the spike has closely-arranged bracts, from which proceed cream-white flowers with a yellow blotch on the lip, and two crisp bands with red edges running from the base. The flowers open three or four at a time.

LAVINGTON PARK.

LAVINGTON PARK, owned formerly by the late Bishop Wilberforce, and purchased about nine or ten years ago by its present owner, James Buchanan, Esq., is situated three and a half miles to the south-east of Petworth.

The creeper-covered Georgian mansion, as is seen in fig. 189, which shows the south front beautifully clothed with Ivies, *Ampelopsis Veitchii* and *Magnolia grandiflora*, stands on sloping ground, facing the Beech-wooded north side of the South Downs. It stands far enough down the slope to admit full sunshine and yet be on high ground, and to allow of a stretch of lawn, croquet and tennis grounds, and shrubberies, which lead to some woodland

walks which are parallel with the hill. In the Bishop's Walk are some beautifully carved, quaint marble seats, and also an image of the King's jester, which was found embedded in an old wall in Holborn that went through the great fire of London. The formal flower garden is at the east end of the residence, in an exposed position. A little beyond the flower beds on the lawn is a magnificent specimen tree of the black Walnut.

From the terrace on the north side are fine views over a vast stretch of fertile park and agricultural land. In the distance can be seen Petworth Park, Leith Hill monument, and Black Down. The park contains many fine trees planted by the late Bishop Wilberforce, including a distinct-looking Cedar raised from seed which the late King Edward collected in Palestine when he was Prince of Wales.

The rock garden, though small, is a very well built structure by Messrs. Cheal. Situated at the west end and close to the mansion, it contains a good collection of well-established Alpines, among which are conspicuous extra good specimens of *Gentiana acaulis*, *Aubrietias*, *Dianthus*, *Saxifraga Cibranii*, *Sedums* in variety, *Scabiosa*, *Parnassia*, *Polygonum capitatum* and *Hepaticas*. Upon the higher parts are some very fine spikes of *Yucca filamentosa*, *Zauschneria californica*, *Helianthemums* and *Cistus*.

The walled-in kitchen and flower garden is situated near to the west side of the mansion. A glorious mass of *Polygonum baldschuanicum* hangs over the top of the corner of the wall. Within the enclosure two borders, each 180 yards long, with a closely-mown grass path between them, present a wealth of flowers such as is seldom seen, the lie of the land enabling the visitor to see practically the whole of the garden.

The border to the right is, with the exception of a few annuals, purely herbaceous, and contains all the popular varieties in bold masses, which produce a much better effect than isolated plants. The border to the left is partly herbaceous, but contains also annuals and the usual summer bedding plants. Last season it was bright with great masses of *Viola* Mrs. Chichester, *Phlox Drummondii*, herbaceous *Phloxes*, *Mignonette* (in several varieties), *Antirrhinums*, *Salpiglossis*, *Montbretias*, *Prometheus*, *Westwick*, *George Davison* and others; *Pentstemons*, *Petunias*, *Verbenas*, *Scented-Leaved Pelargonium* *Lady Plymouth*, *Fuchsias*, *Heliotropes* and many other flowers, mostly planted to colour, and at intervals of a few yards standards of the old Peruvian *Heliotrope* (the sweetest of all) were planted for their scent. At the west end of the border was planted a mass of several hundred specimens of the double-flowered *Marguerite* Mrs. F. Sander, flowering very freely and "true to character," with only here and there a single flower.

The vegetable quarters were formed by three grass walks, running (with the exception of borders at each end) the whole length of the garden, one central, the one between the flower borders already mentioned and one between the woodland and the garden. A paved, flagged path runs the whole length of the garden, alongside the mixed flower border, and a central cross walk 70 yards long was flanked on each side by a border 8 feet wide, planted in large blocks in distinct colours with East Lothian Stocks, 5,000 in all. They made a magnificent show at the middle of July (see fig. 190). Most of the borders along the walks are backed with young fruit trees. On the central cross wall are espalier Pear trees, and on the others bush or pyramid Apples.

The soil and culture must be ideal for Apples, as all the varieties appear very healthy in growth, and an orchard of young trees outside the garden proper is doing remarkably well. The south wall has several young fan-shaped Peaches and Nectarines trained on it, and on

the west end of the south wall are fine old trees of Brown Turkey Fig.

The Dower House is only about a hundred yards to the east of the mansion, on the right-hand side of the drive leading to Petworth. Between the flower garden and the Dower House is an imposing group of weeping standards of the Rose Dorothy Perkins, with a shrubbery as a background, in which were noticed good groups of variegated Ligustrum, Purple Plum, Deutzia crenata, Philadelphus, Olearia Haastii, Buddleias, Viburnum Tinus, V. Opulus, V. plicatum, Choysia ternata, Hollies, Lilacs, and Portugal Laurels.

The Dower House is surrounded partly with lawn, herbaceous borders and beds, shrubs and beds of Begonia Lafayette and Paul Crampel.

On the south side of the house is a fine Bay tree quite 30 feet high and nearly as much through, and on the opposite side is a particularly fine specimen of the Turkey Oak. By the way, the Dower House is known as "Beechwood," and was at one time the home of the late Cardinal Manning. Its gardens are now under the supervision of Mr. Streeter, the head gardener at Lavington, and the kitchen garden is cropped in connection with the main garden of Lavington. From this garden we enter "Botany Bay," a

exhibits at the shows); and under them were staged Cypridium. In the greenhouse more Fuchsias were trained up the roof, and Clerodendron fallax, Lilium speciosum, Hydrangea paniculata and H. hortensis were growing on the stages, whilst suspended from the roof were baskets of Begonia Lloydii. In the stove, Bananas (*Musa Cavendishii*) were represented by four fruiting plants in large tubs, and smaller plants for succession. *Eucharis grandiflora*, Caladiums, Codiaeums, Palms and Nepenthes were especially good. The vines generally appeared well looked after and in excellent condition, a remark that applies equally to the Peaches and Nectarines, Cherries and Figs, and Liliams and Tomatos. Upon the opposite side of the wall are the Orchid houses, fruit room, Mushroom house and stovehole; the latter has two sectional boilers set so that they may be worked separately or together. The Orchids consist mainly of Cattleyas, Cymbidiums and Odonoglossums. In the span-roofed, growing houses and frame ground the principal things noted were 200 Cyclamen, 200 Begonia Gloire de Lorraine, nearly 3 feet high and as far through. Carnations are represented by 800 perpetual flowering and 200 "Malmaisons." The old plants of Tree Carnations were flowering profusely under

and white, and the plant is apparently a free grower. In Edinburgh this year it was shown by Mr. Pirie in his first prize collection of twenty-four Alpines, and also by Messrs. Cunningham, Fraser and Co.

ROMANZOFFIA UNALACHCENSIS.

ROMANZOFFIA SITCHENSIS is a most unreliable plant; I have lost it more than once in trying to establish it—an experience common to many. Last autumn, however, a friend wrote me from British Columbia to the effect that he was sending me a few plants of the rarer *Romanzoffia unalachcensis*, a species allied to *R. sitchensis*, which he hoped might prove more amenable than the latter. In due time the plants arrived, and some were planted in the moraine and the remainder in dry soil in the rock garden. Three little plants have appeared in the latter and one is now in bloom. It is only as yet an inch or so high, with white flowers and smooth leaves, closely resembling a Saxifrage, though belonging to the Hydrophyllaceae. *S. Arnott.*

PRIMULA WINTERI.

KNOWING that many Alpine Primulas grow in rocky clefts where the soil, though moist, has thorough drainage, and where the roots are kept cool by rocks, and the atmosphere constantly moist from hovering clouds, I placed *Primula Winteri* in a pot in a shallow enamelled iron dish about $\frac{3}{4}$ inch deep, and filled it with water to about $\frac{1}{2}$ inch in depth, placing a cloche over the pot. There was thus a constantly damp atmosphere, but as the cloche did not touch the whole of the dish, there was also circulation of air. Under these conditions the plant thrived, and I was able to obtain two young plants from it. As soon as the latter were large enough to form lateral roots I cut through the root-stock, but let the plants remain in the pot until the early autumn, and then planted them out. The young plants flowered freely this season. *E. H.*

NOTES ON FRENCH HORTICULTURE.

THE PARIS SHOW.

THE annual spring exhibition of the National Horticultural Society of France, held at Cours la Reine on May 20-26, was inaugurated by the President of the Republic. As in former years, the exhibition proved a great social event, and as usual the aim of the exhibitors was to produce rather a magnificent mass effect than to display the beauty of individual plants. The display was indeed magnificent with the large specimen Rhododendrons and the masses of mixed annual, biennial and perennial plants. The most important floral exhibits were the Roses, amongst which the Wichuraiana hybrids and Polyantha varieties trained in graceful arches proved more popular than ever. Among other plants numerously exhibited were Carnations, Iris (germanica and Kaempferi), Sweet Peas, tuberos Begonias, Nymphaeas (in pools), Hydrangeas, Schizanthus, and Calceolarias. Among outside exhibits the trained fruit trees were especially noteworthy. Rock gardens are growing in favour in France, and were represented by four important exhibits. One, which received the grand prix d'honneur, represented a mountain scene, the summit of which attained to the height of the tent. In addition to the sections devoted to floral art, garden architecture and horticultural education, "sundries" were well represented, and there was as usual a "salon" in which were exhibited oil paintings, water-colours and pastels of flowers and garden scenes.

Among new or interesting plants the following were noted:—A series of new forms of Iris germanica, hybrids of Ricardii (shown by M. Maron, Brunoy), and the variety Madame Durand (shown by M. Denis). New large-flowered varieties of

[Photograph by F. Coze.]

FIG. 189.—LAVINGTON PARK, SUSSEX, THE RESIDENCE OF JAMES BUCHANAN, ESQ.

delightful valley with a stream meandering throughout its length, with here and there miniature waterfalls which end in a spacious duck pond. The stream is bordered by spacious sloping banks, and here and there under the shade of trees are masses of hardy Ferns, apparently self-sown. At the entrance there is also a fine stretch of water, shallow for the greater part, and alive with trout. Several varieties of Nymphaea are getting nicely established, and masses of *Primula japonica* and its varieties; Japanese Iris, Polygonum, Carex, red and yellow, Weeping Willows, and other semi-aquatics are planted near the water's edge, whilst higher up the banks are grouped Bamboos, Golden Elder, Buddleias, Tamarisk, Spanish Broom, Viburnum, Laburnums, Olearia Haastii, and other shrubs.

THE INDOOR GARDEN.

The indoor garden includes a range of three-quarter-span, Teak-wood houses, built by Mackenzie and Moncur. They face to the south and consist of a Palmhouse, greenhouse, stove, two vineries and two Peach houses. Upon entering one is immediately struck by the splendid condition of the plants. In the Palmhouse were well-flowered Fuchsias, trained 10 feet high to the roof (similar to Messrs. Veitch's splendid

the north side of one of the houses. Other plants especially good were Begonia Emily Clibran, Achimenes, Calanthes, Euphorbia jacquiniiflora, Poinsettias, Gloxinias, Plumbago coccinea superba, and Begonia Gloire de Sceaux. *Thomas S. H. Down.*

ALPINE GARDEN.

HABERLEA AUSTINII.

IN former years a very pretty *Haberlea* has been shown at the Edinburgh spring exhibition, and this season it attracted even more notice than usual. If I remember aright, it was shown by Mr. W. G. Pirie, gardener to Mr. C. W. Cowan, Dalhousie Castle, in his exhibit of Alpine flowers a year or so earlier than 1913, and I was much pleased with it. The plant was first shown as *H. Ferdinandii-Coburgii* Austin's variety, or *H. kewensis*, if I remember aright. Since last year the plant has received more attention and, being considered distinct, the name of *H. Austinii* has been suggested for it. This is in honour of the raiser, Mr. Austin, of Messrs. Cunningham, Fraser and Co.'s Comely Bank Nurseries, Edinburgh, where the plant was raised from seeds. The flowers are coloured lilac or violet

l. germanica, *Diane*, *Magnifica*, *Moncey*, *Opera*, *Velouté*, *La Neige*, were shown by MM. Vimorin, Andriex and Cie (Paris). A new *Polyantha* Rose, *Betsy van Nes*, and a Mrs. Cut-bush with red flowers, were exhibited by M. Munch, of Leuben, Saxony.

A huet of *Madame Herriot* was shown by M. Pernet Ducher, of Lyons. Hybrid *ingosas*, *Conrad Ferdinand Meyer* (rose), and *Nova Zembla* (white), vigorous varieties, very early and able to withstand low temperatures (exhibited by M. Robichon, of Vitry). *Adiantum tenerum*, with very delicate and light foliage, named *Monsieur Pellerin de la Touche*, was shown by M. Le Contoux, of Chesnay.

Of the 118 names on the general catalogue of exhibitors of plants only four or five were those of private gardeners: whereas no fewer than 150 names occur as under the title of sundry industries related with horticulture.

The rock garden of M. Ferard received a 1st

infants' gardens. For those from nine to thirteen are provided school gardens, in which the children pass daily several hours working each on a special plot. Prizes are given for the best kept plot, and a school exhibition is held annually in August. For adults gardening competitions are held, and prizes are distributed at a grand fête and banquet presided over by the Director of the Society.

Every effort is made to interest the miner in gardening, seeds and cuttings are distributed, and small books and leaflets are prepared and circulated free. The experiment at Lens deserves to be followed widely in other industrial centres in France; for although much has been done already to satisfy the land hunger, which is even more marked among French than among English town dwellers, no traveller in the great industrial regions of France can doubt but that there is ample room for more experiments on these lines. *A. Monnier.*

Rose Society, Chrysanthemum Society of America, and other national bodies, as well as the various horticultural societies and gardeners' and florists' clubs, to affiliate with it. At present the membership of the S.A.F., as it is commonly called, is only one-tenth that of the Royal Horticultural Society, and its members are mostly connected with the trade. Of late years strong efforts have been made to attract private gardeners and amateurs, so far with but moderate success. It is unfortunate that the title American Horticultural Society was not adopted at the outset, and until some more suitable title is used the growth of this excellent body will, I am afraid, be comparatively slow. Even with its somewhat limited membership, however, the S.A.F. has accomplished a great deal for the benefit of the trade in America, and it is well to remember in this connection that we have 10,000 florists in America, which is probably treble the number of the private gardeners over here.

FIG. 190.—BORDERS OF ANNUALS AT LAVINGTON PARK.

(See p. 410.)

[Photograph by F. Coze.]

grand prix d'honneur, and a 2nd grand prix was awarded to M. Nonin for climbing Roses.

Among British exhibitors were Messrs. Sutton and Sons, Reading (scientific horticultural exhibit), Mr. Engelmann, of Saffron Walden (Carnations), Mr. Dutton, of Iver, Bucks (Carnations), and Mr. Clark, of Dover (Sweet Peas and new plants).

HORTICULTURAL CONGRESS.

THE Congress held during the exhibition, on May 22, discussed the following subjects:—"Workmen's Gardens," "Influence of Radio-activity and of Catalyses on Vegetation," "Co-operative Societies for the Sale of Horticultural Produce," "New Systems of Heating Glass-houses," "Deleterious Effects of Smoke, etc., on Plants."

Full reports of the papers may be read in the *Journal* of the French Society, and we may confine ourselves to a reference to the important communication by M. Choquet on the Workmen's Gardens of the Society of Mines at Lens. The work undertaken concerns adults and children. For the youngest children there are

AMERICAN NOTES.

THE SOCIETY OF AMERICAN FLORISTS.

THIS, the strongest trade organisation in America, will meet in Boston next August to hold its annual convention, after an absence of twenty-four years. The local Board of Management is expecting an attendance of 3,000 visitors, and is making extensive plans to entertain them. A feature of this convention will be a "Convention Garden," covering ten acres of ground, located in the Back Bay Fens. This garden is being tastefully laid out, and in it numerous trade growers will make attractive and imposing displays of trees, shrubs, and other plants and flowers which are likely to be interesting in mid-August. The local Board of Management receives plants and cases for all exhibits, making a charge per square foot for the same.

The Society of American Florists and Ornamental Horticulturists is endeavouring to formulate plans which will encourage such bodies as the American Carnation Society, American

OPPORTUNITIES FOR GARDENERS IN AMERICA.

IT would be well for any gardeners who are planning to try their fortunes on this side of the Atlantic not to be too much carried away by the optimistic reports which I have read of the conditions here. As a matter of fact, trade is at a lower ebb and more people are unemployed than has been the case at any time during the past twenty years. While the gardening fraternity has suffered less than most other callings, there are very few openings for head gardeners and less than usual for assistants, and although at this busy season practically all have some employment, chances are that unless trade improves a good many will be idle another fall. Even in California, which has been looked upon as a Mecca for Eastern gardeners, conditions are bad. A recent letter from a friend there stated that he knew of a score of English and Scotch gardeners there who would be very happy if they had sufficient money to pay their car fare East again. *William N. Craig, Brookline, Mass., U.S.A.*

TREES AND SHRUBS.

THE ARNOLD ARBORETUM IN MAY.*

THE number of trees and shrubs really valuable here which Western Europe has contributed to New England plantations and gardens is not large. Of the trees the Beech, two or three of the Elms, the Birches, the Mountain Ash, the Laburnums, the Norway Maple, the Hawthorn, the Hornbeam, the Poplar, several Willows, the Alder, two or three of the Cherries, the Plum, the Apple and the Pear flourish in this climate. Although some of them will drag out a more or less unhappy existence for several years, the Oaks of Western Europe, the Ash, the Sycamore Maple, and all the conifers are not desirable trees for our region. From Western Europe, too, we have obtained a few shrubs which are important in New England gardens. The Heather gives summer brightness to New England gardens and hillsides, and the little *Daphne Cneorum*, a native of the mountains of Central Europe, is now covered with its clusters of fragrant rose-pink flowers. One of the most beautiful of all dwarf shrubs suitable for the decoration of the rock garden, it is rather capricious as to soil and situation, and does not always flourish in this country as well as it does in the Arboretum.

None of the Barberries which have been brought into our gardens in the last thirty years is more useful than the common European *Berberis vulgaris*, which has long been naturalised in eastern Massachusetts and years ago was selected by one of the wise men of Boston as a typical New England plant for the decoration of a monument to be erected to some departed New England worthy. For thirty years, too, much attention has been paid to the introduction and cultivation of the different species of Privet from Eastern Asia, but there is not one among them which is as valuable in New England as the common Privet of Europe, which must have been cultivated here for two hundred years and is now sparingly naturalised in some of the eastern states. The black and shining berries in large terminal clusters are unsurpassed in beauty by those of any other black-fruited shrub which can be grown here, and as they remain in good condition until into the winter they are valuable on the plants and, when cut, for late autumn and early winter decorations. Among the shrubs of Western Europe which are really valuable in New England must be included the Wayfaring tree, *Viburnum lantana*. With the exception of the Korean *Viburnum Carlesii* mentioned in a recent bulletin, and of our native northern Hobblebush (*Viburnum alnifolium*), the Wayfaring tree is the earliest of the *Viburnums* to flower. It is a tall, compact, round-headed shrub with large, thick, dark-green leaves and broad, compact, convex clusters of white flowers. The fruit when fully grown is bright red but finally turns black, fruits of the two colours often appearing at the same time in the same cluster. This shrub is therefore as beautiful in the early autumn as it is in the middle of May; it can be seen in the general *Viburnum* collection near the junction of the Bussey Hill and Valley Roads, and it has been largely planted in the Boston parks. Near it and just coming into flower are several plants of *Viburnum burejaeticum* from Manchuria, Korea and Northern China. This is a neat shrub with small leaves and small compact clusters of creamy-white flowers, which are followed by small black fruits. As compared with most of the American *Viburnums* it has little to recommend it as an ornamental plant; indeed, with a few exceptions, the Eastern Asiatic *Viburnums* are less valuable than the Eastern American species, among which are found garden shrubs of the first class. *Viburnum dentatum* and *V. Wrightii* from Japan, with bright red fruits, have no American counterparts, however, and should therefore be

cultivated for the autumn garden. These two species will soon be in flower in the *Viburnum* collection, where can now be seen nearly every species and variety which can be grown in this climate.

The large creamy-white flowers of *Magnolia Fraseri* are already opening and the leaves are

FIG. 191.—IRIS KASHMIR WHITE.
R.H.S. Award of Merit, June 3, 1914.
(See p. 402 ante.)

half-grown. This is a small pyramidal tree of rather open habit from the slopes of the Appalachian Mountains from Southern Virginia southward, sometimes growing on the headwaters of the Savannah River, where it is most abundant, to the height of 30 or 40 feet. In cultivation it begins to flower when not more than half that size, and here in the Arboretum it flowers abun-

dantly every year and is perfectly hardy. This beautiful tree is still too rare in American collections. The much smaller, greenish or yellowish-green flowers of the Cucumber tree (*Magnolia acuminata*) will soon follow those of *M. Fraseri*. The Cucumber tree, which under favourable conditions sometimes attains the height of 80 or 90 feet, is the largest *Magnolia* which can be grown in New England, and the most northern in its range of all the American species. The flowers of the Cucumber tree will soon be followed by those of another American species, *Magnolia cordata*. This in the Arboretum is a smaller tree with darker green leaves and small, cup-shaped, canary-yellow flowers. This *Magnolia* was discovered more than a century ago by the French botanist Michaux somewhere on the headwaters of the Savannah River in Georgia or South Carolina. A little later it was found by Michaux and his son, F. A. Michaux, in the neighbourhood of Augusta, Georgia. It was introduced into France by Michaux and the descendants of these trees are now cultivated in the United States and Europe. For many years attempts to rediscover this tree in the regions visited by Michaux have been unsuccessful, and it is interesting, therefore, to report that the Berckmans of Augusta, Georgia, have recently found *Magnolia cordata* in two stations a few miles south and west of Augusta. The plants are growing in upland Oak and Pine woods, the largest of them being 7 or 8 feet tall. The plants begin to flower when not more than 3 feet high, and in April of this year some of these shrubs bore 40 or 50 flowers. In cultivation *Magnolia cordata* is always a grafted tree, but it is not probable that the cultivated trees owe their greater size to a stronger stock, and the small size of the plants discovered near Augusta may be due to dry soil and a hot climate, and *Magnolia cordata* as a tree may still be found in some of the moist, rich valleys of the small streams flowing down the eastern slopes of the Blue Ridge.

Several handsome American Hawthorns (*Crataegus*) are in full bloom, leading a procession which will last for nearly six weeks. The earliest of these plants to flower here belong to the *Mulles* section of the genus in which some twenty species are now recognised. They are all shapely round-topped trees, some of them growing to a comparatively large size. The flowers are large, in broad, many-flowered clusters: the leaves are broad, thin and long-stalked, and on most of the species begin to unfold as the flowers open. The fruit of these plants is globose or pear-shaped, crimson, scarlet or rarely yellow, and of excellent flavour. The plants of this group are comparatively rare in the east: they do not extend into the south-eastern states, and are most abundant in the region from Illinois and Iowa, through Missouri and Arkansas, to Eastern Texas. Of this group there are now in flower at the South Street entrance large plants of *C. mollis*, *C. submollis* and *C. arkansana*. The last is a particularly valuable plant, as it retains its brilliant fruit until late in the season and longer than the other plants of this group. Another interesting plant of this group, *C. Arnoldiana*, is valuable because the fruit ripens in August when showy fruits are rare here. This tree was first discovered growing wild in the Arboretum and is still known only from a few stations. It is one of the few species of *Crataegus* which can be easily recognised in winter, when its strongly zigzag branches are conspicuous. There are large plants of this tree on the left of the Centre Street entrance, and there are a number of them on the Valley Road in front of the Oak Collection. All of the species of the *Mollis* group are American with one exception, *Crataegus peregrina*, which is probably a native of Persia. From the American species it differs in the colour of the fruit, which is dark purple, unlike that of any American Hawthorn. This plant is in flower in the old *Crataegus* Collection on the bank between

* Bulletin No. 55 (Arnold Arboretum).

the Shrub Collection and the Arborway boundary of the Arboretum, in which there are also plants in flower of *C. arkansana* and *C. Arnoldiana*.

Many plants in the Plum Collection now deserve inspection, notably *Prunus hortulana* and *P. Munsoniana*, both natives of the Missouri-Arkansas-Texas region, the latter the Wild Goose Plum of pomologists. Many of the early-flowering Crab Apples are still in good condition and the flowers of many others are still to open.

In the general Rhododendron Collection at the base of Hemlock Hill *R. carolinianum* is in flower. This is a native of the slopes of the southern Appalachian Mountains. Although this plant was sent to England more than a century ago, it has been entirely lost sight of until a few years ago, having been confused with *R. minus* or *punctatum*, a southern plant of lower altitudes, different habit and foliage, and less attractive flowers. *R. carolinianum* flourishes in the shade and in full exposure to the sun. It is a dwarf plant of compact habit; the leaves are dark green, and the comparatively small pink flowers are borne in compact clusters. It is, perhaps, as hardy in New England as any Rhododendron, and it is certainly a plant of great promise either for the decoration of parks and gardens or a possible element in a new race of hybrids. Several plants of Rhododendron coreanum are in flower on Azaëa Path. This species, which was discovered by Mr. Jack in Korea, is also a plant of much promise; it is one of the species with deciduous or nearly deciduous leaves; the habit is good, and the abundant flowers are of a pleasant rose-purple colour. Judging by the experience with it in the Arboretum during the last two or three years, it is one of the best of the recent introductions of its class.

SUMMER PRUNING OF FRUIT TREES.

It is too often the case in gardens that the trained fruit trees appear at midsummer with thickets of strong shoots growing out from them, and later, when the shoots have completed their growth the shoots are cut back to 6 or 7 inches. This "summer" pruning, which is carried out far too late in the season, is expected to make the shoots plump up fruit buds at the base, but it is rarely successful, nor is it likely ever to be generally satisfactory. I know that in some gardens this sort of practice is made more or less inevitable by reason of the shortness of labour, but the following directions should be carried out where possible.

All fruit trees which form spurs should be gone over whilst the young shoots can be pinched off with the thumb and finger, and, in the case of Plums, which do not like the knife, especially is this necessary to prevent gumming and canker. Pears, Cherries (excepting Morellos) and Apricots should be pinched back carefully to four or five eyes from the base of the shoot; and again, when other shoots form, these should be pinched back in turn to one or two eyes. Not all the tree should be done at once, but rather as far as one can reach up, and after a few days have elapsed the operation can be concluded by treating the top of the tree. There will then be less danger of the fruit dropping than if the operation were done at one time. Not only does this early pinching benefit the tree, but it allows more light and air to reach the fruits. Trees which bear fruit on the young wood, such as Peaches, Nectarines, Figs, and Morello Cherries, should have the shoots thinned out and a proper number trained in. The best shoots are those of medium thickness. Therefore, if one has a choice, reject the weakest, and also those that are rank and strong growing. Cut them clean out at the base, unless there is danger of an empty space, when two or three eyes may be left, which in due time may possibly develop into suitable shoots. It is a good plan to tie

in the young wood over the old and bare shoots, and where this cannot be done, either nail or tie it in, taking care to allow plenty of room for swelling, and always keeping the ultimate shape of the tree in one's mind.

Do not allow the shoots to cross each other, as this, to a trained eye, looks very bad. All

FIG. 192.—*VERBASCUM* "WARLEY ROSE": COLOUR OF FLOWERS ROSE-PINK.

(R.H.S. Award of Merit June 3, 1914. See p. 402 *ante*.)

trees during growth should be kept scrupulously clean, as nothing hinders growth so much as infestations of insect pests. These can easily be prevented now that there are so many reliable washes, etc., on the market, and also if the adage, "a stitch in time saves nine," be borne in mind

Bush and pyramid Apples, Pears and Plums which have been thinned out at the winter pruning, the same method will answer here as advised for spur fruiting or wall trees. The side shoots may be pinched back just the same, but the leaders may be allowed to grow a little longer before being treated, and should then be pinched back with the intention of keeping the trees as shapely as possible, consistent with forming good fruiting spurs.

Standard trees are usually not so strong-growing, and with this kind of tree, if the root system is good, and the branches are not too thick, they may be allowed to grow naturally, leaving any pruning until winter. Much of the treatment depends on the variety, some requiring hardly any pruning. As I have mentioned, Plums, and also sweet Cherries, should not be pruned too much, as they resent the knife. I have in mind some cordon Plum trees, which had been pruned hard in the winter every year, and they make every summer strong, thick shoots which never produce fruit buds at the base. These trees were lifted and re-planted; the severe pruning was modified, and the shoots were pinched as advised during the summer months. This season they are loaded with fruit, which will require thinning. I mention this as coming under my personal notice.

Raspberry canes which have borne fruit should be cut out immediately after the fruit has been gathered, and the young canes for the next season's fruiting will be much finer than if the old ones are left during the winter. Red and White Currants should be pinched back when the leaders have made six or seven leaves, and the side shoots when they have made two or three. In Black Currants the young wood from the base should be encouraged to grow, and, therefore, if the old wood is too thick, as soon as the fruit is gathered thin it out. Gooseberries do not, as a rule, require very much pruning during summer, but any suckers from the base should be cut out. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

NOTICES OF BOOKS.

FLORA OF FORMOSA.*

SOME particulars of Dr. B. Hayata's contributions to the botany of Formosa and of the physical features of the island may be found in the *Gardeners' Chronicle* for January 6, 1912, and the previous volumes of the present publication have also been noticed in these columns. Volume III. comprises thirty-five plates and 222 pages of letterpress. Volumes I. and II. contain, in addition to the figures and descriptions of new plants, a "Conspectus of the Flora of Formosa," in which the classification of Bentham and Hooker's *Genera Plantarum* is followed: Ranunculaceae to Rosaceae in the first volume, and Saxifragaceae to Dipsacaceae in the second. Unfortunately, in one sense, and owing to the great influx of new material, the author has not been able to continue the "Conspectus" in the third volume. In that volume of the *Icones* he begins again with the Ranunculaceae, and figures a selection of novel or interesting plants belonging to various families down to the Ulmaceae and Coniferae. The new plants described include a small number of Monocots, among them *Musa insularimontana* and *M. textilis* var. *Tashiroi*, which "differs very slightly from the type in the more patent petioles, scarlet-purple bracts, and in the young leaves, which are usually reddish on the back"—differences hardly demanding two-thirds of a page of Latin description! *Ancistrocladus hainanensis* is an interesting discovery from the Island of Hainan, as the specific name denotes,

* B. Hayata. *Icones Plantarum Formosensium, nec non et Contributiones ad Floram Formosanam*. Volume III. Taihoku, Formosa, 1913.

but its essential differential characters are not signalled. There are many additions to the genera *Ilex*, *Euonymus*, *Rubus*, *Hydrangea* and *Rhododendron* (about a dozen), also many *Lauraceae*, including eight species of *Cinnamomum*. *Cupuliferae*, too, are represented by many new species, including two of *Carpinus*, ten of *Quercus* and two of *Castanopsis*. Three new species of *Pinus* are described, and two (*P. brevispica* and *P. Uyematsui*) are figured. Of more than passing interest are three new species of *Shortia* (*Diapensiaceae*). *S. transalpina* is a diminutive species from the mountains of the interior, at an altitude of 10,000 feet. *S. exappendiculata* differs, according to the author, from all previously described species of *Shortia*, in the absence of staminodes, the sessile anthers, and in the undivided styles, and he suggests that it might constitute a new genus, which he would call *Shortiopsis*.

Appended to the foregoing is an essay on the systematic position of the curious genus *Mirastemon*, which has also appeared in a German

book during the present year. It will be of the highest value to Orchidists. The plan of the work is to enumerate all known genera of Orchids—grouped as nearly as possible in natural sections—which are capable of being hybridised. Each genus is fully described, and also the species as amply as the scope of the work will allow. Cultural instructions are given from material supplied by Mr. Otto Beyrodt, Mr. H. Janke, Mr. A. Malmquist and Dr. G. Lindau—all experts in their various branches and well known throughout Europe. The work is strictly accurate and complete in its scientific and botanical features, and in its brief historical and cultural details. It will be especially acceptable to the gardener, who, while seeking information on cultural and general details, wishes to educate himself in the botany of the Orchid family. The volume opens with chapters on the general aspect of cultivated Orchids and their introduction, together with illustrations of the structure of different sections of Orchids. The parts of the flowers are given, and a review of the geo-

GENERA OF BRITISH PLANTS.*

This little book will be useful to those who have already had some instruction in the classification of plants, but it is too highly technical for the uninitiated. For example, under "Alismalales" we find the following definition or description:—"Flowers cyclic or hemicyclic; achlamydeous, haplochlamydeous, or diplochlamydeous (homochlamydeous or heterochlamydeous); hypogynous or epigynous"! Of course, this is not so formidable as it looks, but it must be quite unintelligible to the "ordinary reader." To the botanical student unacquainted with the German language it offers the elements of a classification of the higher plants on a system now widely adopted outside of Germany, though still little known in this country. Unfortunately it wants the admirable illustrations of the seventh edition of Engler's *Syllabus*.

THE FLORA OF CHINA.

The fourth part of Sargent's *Plantae Wilsonianae* is a volume of 250 pages, containing a descriptive account of Wilson's collections representative of about a score of families, including the *Coniferae* (in a wide sense), the *Lauraceae*, the *Leguminosae*, the *Rutaceae*, the *Rhamnaceae*, etc. The bulk of the volume is the joint work of A. Rehder and Wilson. Dr. A. B. Rendle is responsible for the *Bambuseae*, Mr. J. S. Gamble for the *Lauraceae*, and Mr. W. G. Craib for the *Leguminosae*. H. Fakeda, A. K. Schindler, S. T. Dunn, C. S. Sargent, C. Schneider and A. Lingelsheim are also contributors. As mentioned in the notices of previous parts, Mr. Wilson's field notes and observations add immensely to the value of this descriptive account of his collections. It is not generally known that these collections are illustrated by a series of some 350 incomparable photographs, taken by Wilson himself. There is nothing in the history of botanical collecting to equal Wilson's achievements in this direction. References to the numbers of the photographs are given throughout in the present work. Sets of the photographs are offered for sale. Upwards of sixty pages of this part of the *Plantae Wilsonianae* are devoted to the *Coniferae*, and there are many corrections of the nomenclature current in both herbaria and gardens. Mr. J. S. Gamble's account of the *Lauraceae* is specially valuable, as it was preceded by a long study of the very numerous Malayan members of this family. The delimitation of the genera is very difficult. Judging from Mr. Wilson's remarks on the altitudinal distribution of Chinese *Lauraceae*, few of these will prove hardy in the British Islands. Specially rich in novelties are the *Rutaceae*, the *Rhamnaceae* and the *Sabiaceae*. A change in nomenclature adopted, not originated, by Rehder and Wilson will probably never become general in gardens. It is *Ailanthus caecodendron* for our old friend *A. glandulosa*! W. B. H.

FIG. 193.—*DEUTZIA DISCOLOR* VAR. *ELEGANTISSIMA*; COLOUR OF FLOWERS LILAC-PINK.
(R.H.S. Award of Merit June 3, 1914. See p. 402 ante.)

form in Engler's *Botanische Jahrbucher*. *Mitrastemon Yamamotoi* is a small root parasite, first discovered in the island of Kiushiu, southernmost Japan, about thirty years ago, growing on the superficial roots of *Quercus cuspidata*. As already recorded in these columns, it has been treated alternatively by Makino, the original describer, as a member of the *Rafflesiaceae* and the type of a new family. As the result of a fuller investigation of the external morphology and of the anatomy of the plant, Dr. Hayata now classifies it as the type of a new tribe of the *Rafflesiaceae*, which the floral and minute characters seem to justify.

DIE ORCHIDEEN.*

This is the first number of a very important and excellent work on Orchids by Dr. Rudolf Schlechter, which will be completed in ten num-

graphical distribution of the genera. The enumeration begins with *Cypripedilinae*, divided into four sections: *Selenipedilum* Rehb. f., a small and little-known section; *Cypripedium* L., the hardy class; *Phragmopedilum*, Rolfe, usually called *Selenipedium* in gardens; and *Paphiopedilum* Pfitzer, the bulk of those known in gardens as *Cypripedium*, including *C. barbatum*, and *C. insigne*. These divisions are well sustained by structural differences, but the ordinary gardener will probably stick to his "Cypripedium." *Habenariinae*, including the Orchis and other terrestrial species. *Disceinae*—*Disa*, *Satyrion*, and other genera of terrestrial Orchids, are fully dealt with.

Some excellent illustrations, including coloured plates of *Odontoglossum grande* and *Paphiopedalum callosum*, are given, and the volume is well printed. An English edition is contemplated.

HOPS IN UNITED STATES AND GERMANY.—

The Board of Agriculture and Fisheries reports that His Majesty's Consul at Portland, Oregon, U.S.A., states (May 16) that there is said to be a moderate demand for the new crop of Hops and for Oregon contracts, a few of which have been obtained at 7d per lb. Although a number of hills are dead, the new acreage is expected to make up more than the loss, and the outlook at present is favourable for a good crop, although nothing definite can yet be reported. Official reports give the condition of Hops as between average and good in Wurtemberg on June 1, and as good in Bavaria at the end of May.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. COOKSON,
Oakwood, Wylam-on-Tyne.

ANGULOA.—It is desirable to re-pot the plants at a season when the roots are active, and as the young growths develop at the same time as the flowers it is best to attend to any re-potting requirements immediately the flowers are over. A suitable compost consists of equal portions of turfy loam and peat, with sufficient sand and charcoal intermixed to render the compost porous. The materials should be pressed moderately firm, and the pots filled to about 1 inch from the rim. If the surface is covered with a layer of chopped Sphagnum-moss it will add considerably to the appearance of the plants. After re-potting, afford water sparingly until the plants are re-established, but water the roots freely when the pots become filled with roots. The leaves should be examined carefully for the presence of scale and other insect pests; it will be found that sponging with a weak insecticide is the most effectual means of keeping these pests in check.

CATASETUM.—Many *Catasetum*s are growing freely and producing their flower-scapes. Nearly all these Orchids require hot, humid conditions during their season of growth, also an abundance of root moisture until the growths have matured. We grow them in the plant stove, where they obtain plenty of light and are syringed daily. They succeed best in baskets or shallow pans suspended near to the roof-glass. The roots should not be disturbed more frequently than is necessary, as they form a matted mass of roots which need very little compost to sustain them. In re-potting use a compost of a lasting nature, such as is provided by a mixture of equal portions of *Osmunda* and *Polypodium* fibres, and let there be ample drainage provided. This kind of work should be done when the roots are first becoming active.

ORCHIDS WITH TERETE LEAVES.—Plants of *Vanda teres* and others of its kind which have recently passed out of flower are rooting freely. Plants that have become leggy from the loss of their lower leaves may be cut through the stems into convenient lengths and re-potted. Success will depend on the position in which they are grown and the treatment they receive: the nature of the compost is a secondary consideration. Plenty of broken crocks intermixed with chopped, living Sphagnum-moss, pressed firmly about the base of the plants, is all that is required. They flourish in full sunshine in an extremely humid atmosphere. The roots may be well soaked with rainwater as soon as the work of re-potting is completed, and syringing the plants daily with chilled water is recommended until growth becomes matured. Afterwards gradually reduce the amount of water and keep the compost perfectly dry during the dormant season.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

SPRING BEDDING PLANTS.—The best plants of such subjects as *Aubrietia* and *Polyanthus*, having been selected and marked for stock, may be divided into small portions, each with a few roots attached, and re-planted in a partially-shaded corner of the reserve garden. If shade cannot be secured, a few small evergreen branches stuck amongst the plants will answer the purpose equally well. Sprinkle the branches with water during hot sunshine in order to promote a cool, humid atmosphere, until new roots form. Daisies, *Polyanthuses*, *Pulmonarias*, and *Veronica incana* are all best propagated from single crowns. *Wallflowers*, *Silenes*, *Myosotis*, *Stocks*, *Polyanthus* to colour, and *Alyssum saxatile compacta* are best raised from seed sown at once in cold frames, which

should be shaded until germination takes place. Sow the seeds thinly in order that the seedlings may have room to develop hardy and sturdy from the start.

MULCHING.—Flower beds and borders of recently-planted subjects are greatly benefited by a thin mulching of fine leaf-mould, or a dressing of peat-moss passed through a half-inch sieve; apply this also to shallow-rooting plants such as tuberous and fibrous-rooted *Begonias*. All flower beds and borders require mulchings of short manure, a little stronger in character than the above. To prevent the birds from scratching the material place stones on it underneath the leaves of the plants.

ANNUALS.—Preserve a fine surface tilth amongst annuals by the constant use of the small Dutch hoe; this will also prevent evaporation of moisture from the ground. A surface mulching is preferable to continuous waterings by the hose.

SWEET PEAS.—Finish staking the plants, and attend daily to the training of the young growths, distributing them evenly. If blooms are required for exhibition purposes, pinch out the lateral growths, thus concentrating the energies of the plant into the main stem, and afford weak stimulants applied a little and often. An occasional sprinkling of soot will be beneficial, and it should be washed into the ground with water from the hose.

CARNATIONS.—Afford a mulching to these plants as recommended for *Begonias*. To destroy green fly, dip the points of the shoots in soapy water, adding extract of nicotine in the proportion of one teaspoonful to four gallons of water. Train the growths naturally on spiral, galvanised wires (those painted green are the best). *Lady Hermione* is an excellent variety for planting out-of-doors because of its robust constitution. For stimulants, use specially compounded manures, liquid manure and soot-water—the soot-water gives tone and colour to both blooms and foliage.

SUMMER CHRYSANTHEMUMS.—Pinch systematically the growths to secure evenly-balanced plants, using small stakes to spread out the growths as they develop. The earliest varieties should be stopped not later than the end of the present month, but this work must be regulated in accordance with the date at which the plants are required to flower. To secure the best results in blooming, hoe and water the soil constantly. Endeavour to preserve a neatness in the garden and freedom from insect pests, which at this season soon cause irreparable damage if their presence is overlooked.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY,
Knowsley Hall, Lancashire.

PELARGONIUM.—The more forward of the plants rooted in February are ready for transplantation into 7 or 8-inch pots, and the later-struck cuttings into 5½ or 6-inch pots. The compost may consist of three parts turfy loam, one part each of manure from a spent Mushroom bed and leaf-mould, adding sufficient sand to ensure porosity, and a 6-inch potful of bone-meal to every three bushels of the compost. Mix the materials thoroughly and leave them in a heap for a few days. Use clean, well-drained pots, and place over the crocks a little moss, or some of the coarser compost. The plants to be re-potted should be in a moist condition, so that there may be no necessity for root waterings for several days after potting. Place the plants in a cold frame, on an ash bottom; syringe them and shade from bright sunshine. On mild nights remove the lights, and when the plants are re-established expose them to full sunshine. To produce hard, well-ripened shoots, leave ample space between the pots. Pinch out the points of the shoots to make bushy specimens, and afford water with great care. All kinds of *Pelargonium* may be fed twice weekly with liquid manure made from horse or deer droppings. Remove decayed flowers, and promote a fairly dry atmosphere to prevent the blooms from damping. Train the shoots of Ivy-

leaved *Pelargoniums* to stakes or pillars. Tie lightly the shoots of plants in baskets, but do not destroy the free natural effect of the growth.

CINERARIAS AND CHINESE PRIMULAS require close attention as regards shading and watering, and should be fed liberally. Make another sowing of these plants for later flowering.

CALCEOLARIA.—Cut away untidy growths that have finished flowering, and shade the house during the brightest part of the day. Keep green fly in check by fumigating the plants at regular intervals. Early in July sow seeds on the surface of the soil in pans, and germinate them in a cold frame under a bell-glass.

CAMPANULA PYRAMIDALIS.—Afford frequent applications of liquid manure and soot-water to plants in pots showing flower-spikes. Place the plants under the north side of a wall or hedge to obtain partial shade, and stake each flower-spike to prevent damage by wind. Grow the plants in the open until the flowers begin to open. Re-pot plants raised in autumn and spring before they become pot-bound, and place them on a bed of ashes where the situation is shaded from bright sunshine. If close attention can be given to potting, these plants are preferable to those planted out and lifted for flowering. Sow seeds of *C. calycanthema* to obtain plants for flowering next year.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton
Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buck-
inghamshire.

VINES.—Attend carefully to the watering of vine borders, especially those inside where the vines are swelling their berries. Afford a copious watering with soft, tepid water, and then apply a mulch of half-decayed manure, leaves or similar materials to prevent undue evaporation of moisture from the soil. Vine borders, properly constructed and well drained, are not likely to be harmed by over-watering at this stage. Maintain a genial, growing atmosphere in all vineries, and take advantage of sunny days to air the house, closing the ventilators early in the afternoon with an abundance of atmospheric moisture. Do not neglect the fires, which should be started to meet the declining heat of the sun, and admit a little air through the front and back ventilators to avoid a stagnant condition of the atmosphere. If the atmosphere becomes surcharged with moisture mildew is apt to become troublesome, in which case sprinkle the paths and hot-water pipes with sulphur and increase the amount of heat and air. Thin the Grapes when ready, and remove all superfluous lateral growths. Afford plenty of air and a brisk temperature to Grapes colouring, and keep houses in which the crops are ripe, sweet and clean.

MELONS.—Afford plenty of air, heat, and moisture to succession plants swelling their fruit, and expose them to plenty of sunlight. Regulate plants growing in frames, pinching the shoots at one joint beyond the fruit, avoiding mutilation or injury to the foliage. Place a piece of tile, wood, or glass on the bed beneath the fruits and take care not to over-water the soil during the ripening stage. Pollinate the strongest female blooms as they develop.

FIGS IN POTS.—As soon as the first crop of fruit has been gathered remove the loose portions of former mulchings and apply a fresh rich compost, which will induce the formation of surface-feeding roots for the support of the second crop, which should be light compared with the first crop, if that has been an average one. Attend to the training and regulation of the growth constantly. Plants in unheated houses require all the sun-heat possible, and the ventilators should be closed early in the day with a sun temperature of 80° to 90°. It is advisable to grow the plants on the extension system, allowing the leading shoots to extend without stopping until they have reached the limit of the wires or trellis, afterwards removing them to make room for others growing from the base of the stem. Train the young growths at a suitable distance apart, to enable the wood to ripen properly, and

to secure firm, short-jointed growths. Little or no syringing is required during dull weather, but on fine days ventilate the house early and syringe sufficiently early in the afternoon to allow the foliage to become dry before night-fall.

PINES.—Suckers potted early in spring should now be growing in the pots in which they will fruit. Recently-potted plants should be afforded a steady bottom heat of 80° to 85°, and if the soil is dry water it thoroughly. When the roots are again in an active state and penetrating the new soil only a moderate amount of moisture is necessary. Young plants require constant and careful attention in every particular. Let them have plenty of space during their early stages of growth. Examine them daily for watering, which should be thorough whenever carried out. Ventilate the house early, especially if the morning is bright, so that the foliage may be free of all moisture before the sun's rays reach it, otherwise scorching may occur. Maintain a moist, genial atmosphere by frequently damping the paths and other surfaces several times daily when the weather is favourable, but refrain from promoting much moisture during dull weather, as this causes a soft, unhealthy growth and reduces the vigour of the plant.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

FIGS.—Fig-trees are growing rapidly, and there being very little frost last winter to damage the shoots their condition is satisfactory, with every prospect of a good crop. Young trees have a tendency to make gross growth, and to counteract this inexperienced persons often resort to severe pruning, which is wrong, for it only results in further growth of a similar nature. The proper treatment is to practise root-pruning in the autumn. The branches of young trees should be trained thinly apart, leaving only a sufficient number to furnish the wall-space. All weak growths can be pinched back to the third or fourth leaf. As showing that an extensive and rich rooting medium is not necessary one has only to remember how well Fig trees grow in odd corners with their roots often in a hard road or path. Such trees are invariably seen in robust health, and in favourable seasons they bear good crops. The grower should endeavour to obtain similar results with young trees in other parts of the garden by restricting the roots to a small space, which is the best way to prevent the tree from making gross, unfruitful wood, which seldom ripens properly, and is liable to be cut back by frost in winter. But it must be remembered that when the roots are restricted to a small area they are liable to suffer from an insufficiency of moisture, in which case the fruits would fail to develop. In addition to requiring large quantities of water, such trees need to be fed occasionally in order to help them mature heavy crops of fruit.

CORDON PEARS.—Pinch the side shoots to the fourth or fifth leaf, but allow the leader to extend for the present. It is well to do the work of pinching on two or three occasions, for if too many shoots were removed at one operation it would cause a check to the tree. The work may be commenced at the top branches, and the lower parts done after a day or two. To obtain fruits of the best quality, they should be thinned to a reasonable crop as soon as they commence to swell, but this should not be done before that stage, for large numbers of Pears drop whilst young. In doing this work, take into consideration the age and condition of the tree, and also whether the fruits are of large or small size. For instance, those of the varieties Citron des Carmes and Doyenné d'Été are very small when ripe, and these trees may be allowed to carry large crops. Marguerite Marillat and Triomphe de Vienne are two fine varieties for early exhibition, and if fruits are required for this purpose the trees, and particularly those growing on light, gravelly soils, need to be watered and syringed frequently during times of dry weather. The surface soil also should be top-dressed with a suitable fertiliser, which should be forked into the ground, and the latter afterwards watered; when this has

been done spread a mulch of short manure over the roots. The shoots of fan-shaped and horizontally-trained trees required for extension should be secured in position, and all others not needed for furnishing the tree should be stopped.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, Tynninghame, East Lothian.

LONDON COLEWORTS.—Seeds of this green vegetable sown now and again a few weeks later will furnish plants for cutting from late in October until January. I generally plant the seedlings behind an earlier crop, allowing to each a space of one foot, which is ample room.

BET.—The latest sowing should now be made, selecting one of the larger-growing blood-red varieties. The plants of the previous batch are quite forward enough to be thinned to 1 foot apart, and should there be any blanks, fill these with the thinnings. Stir the surface soil in a thorough manner to destroy weeds and render the soil friable and sweet.

CARROTS.—Thin the main crop of Carrots if this work has not been done already, and if there is space available, which is not always the case, make a last sowing of a stump-rooted variety. I have not found this late sowing to escape the Carrot fly, but others have succeeded with it, and anyhow it is worth trying, for late roots are always appreciated. Guerande is an old and reliable variety for late sowing.

FRENCH BEANS.—The plants sown out-of-doors have come up in splendid condition, and should be thinned to 1 foot apart in the rows. I am aware that it is not unusual to leave them much closer, but unless for a large gathering or two at the beginning, it gives less good results than spacing the plants so that each is all but independent of the other. The thinnings need not be lost if there is room to transplant them elsewhere, but a fresh sowing will give equally good results, though later. Draw to the thinned plants as much soil as can be got from between the rows to steady them during high winds. If growing in properly prepared ground the crop will need nothing further in the way of cultivation; but if the soil is of poor quality, scatter some pigeon manure very thinly, or a good vegetable fertiliser, over the surface previous to breaking it up with the hoe for earthing operations. If it is intended to grow the plants without staking them the shoots should be pinched as soon as they commence to run, to dwarf the plants. Each plant demands 3 feet each way when grown in this manner.

LATE PEAS.—I do not like to be later than this date in sowing the crop for the latest pickings, though in warmer localities it will be too early, and perhaps too late in colder. It is important that the forcing treatment as practised with earlier crops is not applied to this, because, though there may be abundant growth and a fair amount of flowers late in the season, the pods do not fill so well as on plants which are less vigorous, though equally healthy. Thin seeding is also of more importance for this than for any other sowing. I would strongly recommend placing supporting material to the rows at once. It may be noted that the old-fashioned custom of drawing the soil to the stems of the plants previous to staking is of no advantage to the crop, and was adopted merely as a means of keeping the plants upright. If early staking is carried out the earthing-up is not necessary.

THE "FRENCH" GARDEN.

By PAUL AQUATIUS.

CROPS OUT-OF-DOORS.—The earliest planted Cabbage and Cos Lettuces have been marketed, and will be followed by those sown from January onwards. Though the demand for salads diminishes as the season advances it is wise to continue planting small batches of Lettuce at regular intervals until late in September, when the most important batch is sown for winter use. Cos Lettuces are generally preferred dur-

ing the summer, though in certain parts of Lancashire and Ireland Cabbage Lettuces are the most popular kind. Select a well-situated spot for the rearing of seedlings of Lettuce, Endive, Cabbage, Radish, Spinach, and similar plants, preferably one where the crops can be watered as often as necessary. At this time of the year the seeds germinate quickly, therefore sow thinly, thus avoiding damping off, and ensuring hardy and strong plants, which may be set directly from the seed beds to their final quarters. There should be a succession of Cauliflowers obtainable until the first frosts in October. Afford copious waterings at the roots when the inflorescence appears; examine the plants daily, and keep the curd covered carefully. When the plants are ready for marketing such as are not required immediately may be pulled up by the roots and placed in a cellar or cool shed. There should be a constant succession of plants, the batch grown without heat following those from the hot beds; in July those from the cloche beds will continue the supply until those out-of-doors are ready in August. Carrots and Turnips sown in March and April are swelling at the roots, and require watering at least twice weekly. Vegetable Marrows set in frames early in April may be grown now without shelter; the fruits are swelling, and the roots should be kept moist. Owing to the recent frosts the early crop promises to be a very remunerative one. No artificial feeding is necessary, the manure bed giving sufficient nutrition. Prepare ground for the planting of late Celery without delay, enriching it with a heavy dressing of manure. The trenches should not be more than 2 or 3 inches deep, with a space of 3 feet between each, which may be utilised by an immediate sowing or planting of Kidney Beans or Lettuces. Should dry weather continue water frequently the crop of Witloof Chicory to prevent the plants bolting. Tomatos no longer require shelter of the cloches; secure the stems to bamboo canes, and remove all side shoots. Spray with a fungicide as a preventive against disease.

MELONS.—Prune the plants systematically as the growth progresses, examining them for this purpose at least once every week. Allow all side shoots to remain until the fruits are the size of a tennis-ball, when judicious thinning may be commenced, pinching the shoots to one leaf. Keep the plants dry whilst the female flowers are expanded, and ventilate freely in bright weather. Melons planted before May 20 do not require covering, but protection should still be afforded those set later. Water the plants before 9 a.m. to enable the leaves and stems to become dry thoroughly before night.

CUCUMBERS require careful shading, and the glass whitewashed, a syringe being preferable to a brush for doing this. Mulch the ground with dry manure or short hay to prevent the young fruits from damping off. Turn the fruit during growth to prevent the side lying on the ground from turning yellow.

AQUILEGIA CANADENSIS.

MANY of the Aquilegias are perplexing to the cultivator, and some absolutely refuse to thrive, no matter how much care is lavished upon the plants; this is sometimes true of the interesting *A. canadensis*. It would cheer those who have failed with it to see the beautiful tufts in rough, dry places in Canada, where the plant enjoys a soil that is distinctly poor and in places sheltered in a large measure from winds. The writer was astonished last summer to find soil near groups of Pines a warm orange-scarlet from the abundance of those graceful flowers we delight to see in the rock gardens at home. It positively thrives where some things cannot exist, hot suns scorching the ground beneath with strong rays, and winter snows having no injurious effect whatever. It is one of the cheeriest of the many beautiful wild flowers of the Dominion, and a hint as to the places in which it loves to dwell may be useful to those who cultivate it in England. *E. T. Cook, Toronto, Canada.*

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JUNE 16—

Roy. Hort. Soc. Coms. meet and Nat. Gladiolus Soc. combined show. (Masters Memorial Lecture by Prof. J. Bretland Farmer, F.R.S., D.Sc., at 3 p.m.)

WEDNESDAY, JUNE 17—

Yorkshire Gala (3 days).

THURSDAY, JUNE 18—

Linnean Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 59.2°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, June 10 (6 p.m.): Max. 66°; Min. 49°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, June 11 (10 a.m.): Bar. 29.5; Temp. 68°. Weather—Bright Sunshine.

PROVINCES, Wednesday, June 10: Max. 69°, Brighton; Min., 44°, Dover.

SALES FOR THE ENSUING WEEK.

FRIDAY—

Japanese Pigmy Trees, in porcelain pots and pans, by Protheroe and Morris, Central Sale Rooms, 67, 68, Cheapside, London, at 2 p.m.

Apple Scab.

A very thorough and interesting account of Apple Scab is contained in *Bulletin 335* of the Agricultural Experiment Station, Cornell University. Mr. Errett Wallace, the author of the *Bulletin*, comes to the conclusion, as the result of prolonged and careful investigation, that the primary infection which occurs in spring is due mainly and perhaps exclusively to the ascospores which are liberated from the resting fruit-bodies (perithecia) of the fungus. He finds that the perithecia which occur on the fallen leaves burst and discharge their ascospores just about the time that the Apple blossom is opening. As a consequence the first outbreak of the scab fungus (*Venturia inaequalis*) is generally to be observed on the leaves of the blossom buds—for these leaves are the first to expand.

Mr. Wallace points the moral to be drawn from this fact, which is that spraying, if it is to prevent the primary inoculation, must be carried out just before the blossom buds are showing pink. As a spray fluid the author prefers lime-sul-

phur to Bordeaux mixture, and records the observations made by Mr. Waite that good results have also been obtained by the use of self-boiled lime-sulphur to which sulphate of iron is added.

Mr. Wallace finds that from 8 to 15 days elapse between infection and outbreak of scab. During this time the spores which found lodgment on the leaves germinate, their germ tubes penetrate the cuticle, and form hyphae, which extend through the leaf and break out on the surface to form the characteristic patches and the first crop of conidia. These conidia, or summer spores, give rise to secondary infection, which again manifests itself after an incubation period in the outbreak of scabby patches and of a new crop of conidia. From experiments made upon Apples Mr. Wallace concludes that infection follows rainfall very regularly. He estimates that, for the spores to germinate and drive their germ tubes into the tissues, the surface of the leaf must remain wet for some 8 hours, and to this he attributes the fact that scab is more rife on trees with dense heads and on such as grow in sheltered situations. For in an open tree the water drains off the leaves more quickly, and hence such a tree stands a good chance of escaping infection, even though the wind- or insect-borne spores fall upon its leaves.

The relation between moisture on the leaf and germination of the spores leads to the further advice that spraying should be practised when rain is expected rather than when rain is over. Mr. Wallace insists that if the sprayer is able to get his work done only an hour or so before rain falls he will do much to prevent the outbreaks of scab: for, on the one hand, even this short space of time will suffice, in his opinion, to allow the spray fluid to stick on the surface, and, on the other, spraying after the rain is too late, since during a single rainy day the spores adhering to the leaves will germinate, penetrate the leaf, and though the damage will not be manifest for a week or two owing to the "incubation period," it is already done, and the mycelium produced by the germinating spores is out of reach of the spray.

Mr. Wallace does not believe that much, if any, infection is due to hibernating conidia or mycelium. He finds that the conidia do not long retain their powers of germination, and that, although they may resist fairly low temperatures, they are destroyed by prolonged frost. Conditions, however, are different in this country, and it may well be that in our more mild winter climate mycelium, and even conidia, pass unharmed through the winter. Beside spraying and proper attention to pruning, Mr. Wallace recommends that wherever possible the fallen leaves—the harbourers of the winter fruit-bodies of the fungus—should be turned under the soil, and he gives instances which show that outbreaks of scab are less marked when this operation has been performed. As the result of inquiry into the subject of disease-resistance the author concludes that no variety is actu-

ally resistant; nor is he sanguine that the breeder will be able to perform what Nature has failed to do.

Horticulture and Forestry at the Peace Exhibition. Various features at the Anglo-American Exhibition at Shepherd's Bush, the first of the

public functions inaugurated to celebrate the hundred years' peace between the two countries, have been promoted for the most part by honorary committees.

The most important, from our point of view, are the horticultural and forestry committees. The former body has arranged for the planting of the borders and beds with shrubs and flowers, and for exhibitions and conferences to take place at suitable dates during the season, particulars of which were printed in our last issue.

The forestry committee has had to overcome considerable difficulties. In the first place there are fewer exhibitors to draw upon than in the horticultural section, and this season there were several forestry exhibitions already arranged before the committee was formed, notably one at Shrewsbury, to be held in connection with the annual show of the Royal Agricultural Society. When it is remembered that the Shepherd's Bush display must remain open to the public for the long period of five months it will be seen that the demands made upon exhibitors will not permit of the same specimens being sent to provincial shows. Nevertheless, the contributions are sufficiently large and comprehensive to create a considerable amount of interest amongst foresters and wood workers.

The School of Forestry of the University of Cambridge has provided the most extensive exhibit. It consists largely, but not exclusively, of specimens grown in the British Isles, and most of the exotic species selected for exhibition are hardy in the British Isles. Over 220 specimens of planks and boards are shown, each bearing a descriptive label. In many instances a portion of the specimen is polished and the remainder left plain. Every specimen is nicely planed and finished. In addition, there are examples of railway sleepers, plain and creosoted; fence posts illustrating the advantage of using creosoted wood, small manufactured articles, examples illustrating the effects of different methods of pruning, specimens showing injuries caused by squirrels and rabbits, and other interesting objects. Much care has been exercised in arranging the specimens, and the Cambridge authorities are to be congratulated upon the result.

The Duke of Richmond and Gordon has contributed an extensive exhibit from the Gordon Castle Estate, in Morayshire. It includes fine sections of the trunks of common Oak, Larch and Scots Pine, planks of similar woods, flooring boards cut from Scots Pine, sections of Oak suitable for boat building, creosoted posts and rails, specimen of a farm gate made from estate-grown timber by estate workmen, articles of turnery made on the estate; photographs of forest scenes and a

CRINUM POWELLII

A Hybrid Crinum: successful out-of-doors in many parts of Britain

section of Scots Pine upwards of 5 feet in width cut more than a century ago from a tree grown on the estate.

The Earl of Leicester has sent a series of photographs showing the steps taken to reclaim sand dunes in Norfolk, with trunk specimens of Corsican Pine from the dunes. The series demonstrates how forests can be raised on what was originally waste and barren land. Included in the exhibit are various objects manufactured by estate workmen, such as field and wicket gates, mangle rollers, snow and mud shovels and an entrance door. The last-named is made of Oak and is excellent in every way, its perfect finish being the subject of much favourable comment.

From Dupplin Castle, Perth, Sir John Dewar has made an extensive exhibit of pit timber, props, crowns and tramway

Easton Estate, Suffolk. They are of Poplar, and measure over 4 feet in diameter. The tree from which they were cut contained 378 cubic feet of timber in addition to 5 loads of top and faggot wood. Very fine Ash planks are shown from the same estate, also Willows and basket work.

From Darnaway Forest, Forres, the Earl of Moray has sent a valuable exhibit of planks and transverse sections of timber from trees of a good marketable size, specimens of trees showing the difference in the quality of the timber due to different densities of planting, photographs of forest scenery, several cases of insects injurious to forestry, parasitic fungi and other objects.

Messrs. Richardson and Sons have forwarded several photographs of famous

Our Supplementary Illustration.—*Crinum Powellii*, the subject of the Supplementary Illustration, is a well-known hybrid raised from *C. longifolium* crossed with *C. Moorei*. The beautiful deep-rose coloured flowers are more tubular than those of the parent, *C. Moorei*. They have been likened to those of the Belladonna Lily, but they are larger and brighter. The bulb is globose, has a short neck, and bears about twenty leaves, each some three or four feet long. The inflorescence is an umbel of sometimes eight flowers, and the spike is borne well above the foliage, as may be seen on reference to fig. 194, which shows how well the plant succeeds in the gardens at Burford, Dorking. Like many other plants, *Crinum Powellii* does best when allowed to grow for many years undisturbed, and those at Burford have been planted for thirty years. The late Sir TREVOR LAWRENCE informed us that they were set at least 2 feet deep, and in winter received a protective covering of ashes to the depth of about one foot. It is always advisable to

FIG. 194.—*CRINUM POWELLII* IN LADY LAWRENCE'S GARDEN AT BURFORD, SURREY.
(See Supplementary Illustration.)

sleepers, all made of a good quality of Scots Pine wood. He also exhibits railway sleepers, flooring boards, posts and rails (creosoted and plain), planks of Oak, Ash, Larch, Spruce and other timbers. The exhibit is one which is likely to attract the attention of wood merchants, for in each case the timber is shown as it is required for use.

Mr. W. P. Ellmore, Leicester, contributes an extensive collection of the best kinds of Willows used for basket making. They are shown in three ways, unpeeled, as white rods and as buff rods. The Willow industry is well worthy of encouragement in the British Isles, for even the small landowner can look forward to making a margin of profit within two years of planting.

The largest planks in the exhibition come from the Marchioness of Graham,

trees and a fine slab of brown Oak; whilst Mr. Bastin has sent a dozen mounts of insects injurious to forest trees. A comprehensive set of rules and scientific instruments provided by Messrs. Dring and Fage possess considerable interest for foresters and wood workers.

There have not been many Forestry exhibitions in London in recent years, and the present display, though by no means all that we could have hoped, is sufficiently interesting to make us wish that the authorities at Shepherd's Bush had given more care to the arrangement of the exhibits. They should have kept the collections together, arranging them across the hall, instead of separating and dwarfing them by placing the specimens around the walls with exhibits of a very different nature immediately in front of them.

select a warm spot in the garden for members of this family, and those who are acquainted with Kew will know how well *Crinums* succeed in the warm border at the foot of the Palm house. The late Mr. GUMBLETON was very successful with *Crinum Powellii* and its varieties at Belgrove, County Cork. He secured one strong bulb when *C. Powellii* was first sent out by Messrs. HENDERSON, about 1880, and although the plant does not increase very rapidly, eight years after planting the solitary bulb Mr. GUMBLETON had a mass of eighteen fine flower spikes, averaging 4 feet in height, and each bearing from twelve to sixteen flowers. There are forms of *C. Powellii* with paler coloured blossoms, and a very fine white variety named *C. Powellii album*.

FLOWERS IN SEASON.—MESSRS. KEIWAY AND SON send us a few choice varieties of Paeonies as fragrant as the colours are attractive. Amongst the best are *A. G. Vanderbilt*, crimson with purple shading; *Lord Mayor*, very fine rose coloured flower; *Artist*, pale pink, with flesh-coloured centre; *Christabel*, double

white; Cecilia Kelway, a pretty shade of pink; Syren, pink, with lemon centre; Lady Mayoress, pink with very fine white centre; Mulchelney, old rose colour; and two more or less single flowers. R. W. Marsh, crimson-maroon with a mass of bright yellow stamens, and Wild Rose, a perfect single flower, which in shade and appearance is much like a very glorified Dog-rose. From Messrs. ROBERT VEITCH AND SON we have received some fine flowering sprays of Buddleia Colvillei.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held in the Vincent Square Hall, Westminster, on Tuesday, June 16, 1914. At the 3 o'clock meeting in the lecture room, Professor J. B. FARMER, F.R.S., will deliver the eleventh Masters Memorial Lecture, entitled "Certain Aspects of Plants in Their Relation to Their Environments."

NEW SOIL-TILLER.—The *Times*, in its issue for the 8th inst., describes a trial which has just taken place in Kent, near Farningham, of a new rotary soil-tilling machine, which combines the action of plough, cultivator and harrow all in one. The action of the machine resembles that of a Potato digger, except for being backwards instead of transverse, and it leaves the land in an open, loose condition very favourable to subsequent cultivation. It is driven by a 30-h.p. petrol engine, and the largest of the three sizes in which it is obtainable weighs two tons. The cost is about £400, the other sizes being about £300 and £100 respectively, and the three widths are 7 feet, 5 feet, and 3 feet. The machine is capable of cultivating to a depth of from 2 inches to 12 inches; it can tackle hard land as easily as soft, the only difference being that of speed, which varies from 1 foot to 3 feet per second. The total cost of the operation varies from 12s. to 16s. per acre, and the effect considerably exceeds that at present obtained by implements already in use.

THE PRUNE CROP IN OREGON AND WASHINGTON.—The Board of Agriculture and Fisheries is informed by His Majesty's Consul at Portland, Oregon, in a report dated May 13, that the Prune crop of Oregon is estimated to be very small—probably a little over one-tenth of an average crop. From personal observation in Washington, he is of opinion that the crop is very poor in that State also.

R.H.S. GARDENS CLUB.—The members of the R.H.S. Gardens Club hold their annual meeting and outing to-day (Saturday, the 13th inst.). The programme includes a visit to Mr. LEOPOLD DE ROTHSCHILD'S garden at Gunnersbury House, Acton, at 11 a.m., and an inspection of Kew Gardens. Those unable to visit the Gunnersbury House gardens are requested to assemble at the main entrance to Kew Gardens at 2.30 p.m.

THE "FAIRCHILD" LECTURE.—The annual Fairchild lecture will be delivered by the Rev. Dr. HACKETT, late Dean of Waterford, and now vicar of St. Peter's, Belsize Park, on Tuesday, the 23rd inst., at 8 p.m., in Shoreditch parish church. The members of the Worshipful Company of Gardeners, accompanied by the Master and Wardens, will be present. It will be remembered that THOMAS FAIRCHILD, of the parish of St. Leonards, Shoreditch, gardener and cloth-worker of London, by his will, dated February 21, 1723-9, bequeathed to the Trustees of the Charity Children of Hoxton and their successors and the Churchwardens of the Parish of St. Leonard, Shoreditch, and their successors, the sum of £25, to be by them placed out at interest for the payment of 20s. annually for ever for the preaching of a sermon in the church of St. Leonard, Shoreditch, in the afternoon of the Tuesday in every Whitsun week, on "The Wonderful Works of God in the Creation," or on "The Certainty of the Resurrection of the Dead, proved by the certain changes of the animal and vegetable parts of the Creation."

THE NEILL PRIZE IN HORTICULTURE.—The Neill Prize, which is in the gift of the Council of the Royal Caledonian Horticultural Society, has this year been bestowed upon Mr. JAMES GRIEVE, Redbraes Nursery, Edinburgh. The prize consists of the interest of £450, which sum was left many years ago by the late Dr. PATRICK NEILL for the purpose of acknowledging the services of a distinguished Scottish botanist or cultivator, to be awarded every second year. The selection of Mr. GRIEVE as the recipient of the prize on this occasion will be exceedingly popular among Scottish gardeners, by whom he is held in high esteem, both for his professional skill and his genial personal qualities. Mr. GRIEVE is a native of Peebles and served his apprenticeship in the nurseries of Messrs. THOS. GENTLE AND SONS of that town. He afterwards served in Stobo Castle Gardens, and in 1859 he entered the nurseries of Messrs. DICKSONS AND CO. at Pilrig and Redbraes, Edinburgh, and later became nursery manager to the firm. On the removal of Messrs. DICKSONS' nurseries, in 1896, to Craigmillar, Mr. GRIEVE commenced business in partnership with his two sons at the old Redbraes nursery. Mr. GRIEVE has done much useful work in the hybridisation of florist flowers and fruit trees. At Stobo he commenced

Association, and Mr. R. T. LAW has been appointed secretary in his stead.

THE BLACKENING OF FRUIT BLOSSOM.—A paper by Messrs. BARKER AND GROVE in the first number of the *Annals of Applied Biology* (May, 1914) gives a detailed account of the investigations carried out by these authors into the nature of the blackening of fruit blossom, so frequent in Pears in spring. The disease, generally attributed to frost or cold winds, has been shown by Mr. BARKER (*Gardeners' Chronicle*, May 3, 1913, p. 287) to be due to a bacterium which, present in the flower-bud, may cause the pistils of unopened flowers to become discoloured. The first sign of the disease may be manifested by a graying and blackening of the tips of the sepals, or it may appear as minute grey-black spots in the floral receptacles; ultimately the whole receptacle blackens and the disease spreads to the ovary. In rarer cases the stigma is attacked and turns black and the blackening spreads from style to ovary. In any case, the flowers fail to set fruit and generally fall prematurely. The disease spreads rapidly from flower to flower, and from experiments carried out by the authors it is clear that bees and other insects may transfer the bacterium from one flower to another, and thus spread the disease. Nor are only the floral parts attacked. The disease spreads to the vegetative parts and affects the fruit-spurs and not infrequently kills them. Evidence is forthcoming that this black-blossom parasite is not confined to the Pear. It is probable that it attacks the flowers of Apple, Cherry, Gooseberry and Plum, and may also infect the leaves. Of Pears, Bauré d'Amanlis and Catillac are markedly susceptible, but many others are also rendered unfruitful by the parasite. The bacillus has been obtained from discoloured Apple flowers of Beauty of Bath, Bramley's Seedling, Allington Pippin, Devonshire Quarrenden and Duchess of Oldenburgh, and also from Victoria and Myrobella Plum. The bacterium appears to be a soil organism and has been isolated from the soil of fruit plantations. The authors are engaged in a further study of the disease, and it is to be hoped that they may be able to discover means of preventing it.

RHODODENDRON EXHIBITION IN REGENT'S PARK.—The exhibition of Rhododendrons and rock plants, which is being held in Regent's Park by Messrs. WATERER, SONS, AND CRISP, was opened on Monday last by H.H. the Duchess of Teck. It will remain open for public inspection for three weeks.

FRUIT CROPS IN HOLLAND.—The Board of Agriculture and Fisheries is informed by His Majesty's Acting Consul-General at Rotterdam that, according to a report by the Dutch Department of Agriculture of May 20, complaints were being received from several districts that night frosts had done much harm to the fruit crops, which till then were mostly promising. In Limburg especially the damage was considerable, although less on the hills than in the valleys. Here and there drought was doing harm and rain was badly wanted, particularly in Zeeland. In this district much damage was being caused by insect pests. Elsewhere also pests were prevalent, but the vigorous measures adopted had materially lessened the evil. Cherries: Prospects were moderate in the Upper and Lower Betuwe, rather bad in Limburg and the east of North Brabant, and good elsewhere. Red and White Currants were moderate in the Westland, the Bangert, and in Limburg, and good to very good in almost all other districts. Black Currants were moderate to good in most parts of the country. Gooseberries were good in the Upper Betuwe, the centre and west of North Brabant, Ysselmonde and the district around Dordrecht, bad in the Westland and the east of North Brabant, and very good in the island of Walcheren and other parts of the province of Zeeland. Raspberries were good in the centre and west of North Brabant, around Nymegen, in the

FIG. 195.—MR. JAMES GRIEVE, RECIPIENT OF THE NEILL PRIZE.

the crossing of Achimenes; in 1863 he took up the crossing of wild Violas, producing many garden varieties, and his other hybridisation work was chiefly in Carnations, Pinks, Phloxes, and Pentstemons. He is the raiser of Rhododendron Grievei and other hybrid Rhododendrons, and has produced a number of new Apples and other fruits, the Apple James Grieve being named after him. He is a Fellow of the Royal Horticultural Society and of the Edinburgh Botanical Society, and a member of the Royal Caledonian Horticultural Society and the Scottish Horticultural Association; he has served on the Councils of the Botanical Society and the two Scottish horticultural societies. Mr. GRIEVE has lectured on horticultural and nursery work to the employees at the Royal Botanic Garden, Edinburgh, and he has been in much request as a lecturer on florists' flowers and as a judge of these at flower shows in Scotland.

RESIGNATION OF A SECRETARY.—Mr. G. L. BLACKBURN, who is leaving the district, has resigned from the office of secretary to the Leamington Branch of the British Gardeners'

province of Utrecht, and in most parts of Limburg and the Westland, but rather bad in the north of Limburg and the Krimpenerwaard.

SHIPMENT OF DUTCH POTATOS TO PHILADELPHIA.—We learn from the *Board of Trade Journal* that H.M. Consul-General at Philadelphia (Mr. W. POWELL) reports that the first shipment of foreign Potatos to reach Philadelphia since the embargo was placed on Potatos grown on foreign soil arrived at that port on May 1 from the Netherlands. An expert from Washington inspected the Potatos before they were unloaded, and as no evidence of scab or taint of any kind was discovered, the whole shipment was allowed to be unloaded. It is reported that the Potatos were also examined before leaving the Netherlands and were given a certificate of good condition.

RESTRICTIONS ON IMPORTATION OF GOOSEBERRIES IN NORWAY.—With reference to the notice at p. 725 of the *Board of Trade Journal* for March 19 last, respecting the prohibition of the importation into Norway of Gooseberry plants and parts thereof, including fresh Gooseberries, unless special permission for such importation has been granted by the Norwegian Department of Agriculture, the Board of Trade is now in receipt, through the Foreign Office, of copy and translation of a circular of the Norwegian Department of Finance and Customs, dated April 30, which notifies that such permission may be granted on condition that the application is accompanied by a certificate from a publicly appointed horticulturist in the country of origin stating either that the nursery from which the plants are supplied is free from mildew (*stikkelsbaerdraeberen*), or that the plants have been satisfactorily disinfected prior to their despatch. The circular also notifies that permission will not be granted to import Gooseberry plants from abroad to the "Amts" (counties) of Finnmark, Tromsø, Nordland, North Trondhjem, South Trondhjem, Romsdal and North Bergenhus. *The Board of Trade Journal*.

"BOTANICAL MAGAZINE."—*HYPERICUM ASCRON*, tab. 8,557.—This large-flowered St. John's Wort occurs both in the old and new world. Mr. M. L. DE VILMORIN, who obtained seeds from Korea, presented plants to Kew. These gave rather larger flowers than the ordinary form, exceeding 2½ inches in diameter. The flowering stems grow 3 or 4 feet high and are terminated by large corymbs of yellowish flowers, the flowering season being July and August. The species is not a good garden plant, because it is apt to die after a few years, but a fresh stock may be raised readily from seeds.

VITIS THUNBERGII, tab. 8,558.—This plant must not be confused with the so-called *V. Thunbergii*, which is only a very fine form of *Vitis Coignetiae*. The true *Thunbergii* has much smaller, deeply-lobed leaves and is not of such vigorous growth, neither is it so hardy. The leaves, like those of most vines, die off a rich shade of red, and the plant would be valued in gardens in warm districts for its autumn tints.

DEUTZIA MOLLIS, tab. 8,559.—This species was first described by Mr. DUTHIE in the *Gardeners' Chronicle*, October 6, 1906, p. 238, from specimens collected by Mr. E. H. WILSON in Central China. This inflorescence is a many-flowered corymb, the petals being white, sometimes flushed with pink.

TRICYRTIS STOLONIFERA, tab. 8,560.—The species of *Tricyrtis* have curious-looking flowers, and in *T. stolonifera* the maculated foliage is not unlike the leaves of some Orchids. There are some ten species, and *T. stolonifera* is the brightest-flowered of all. The specific name is derived from the stoloniferous habit, which chiefly distinguishes it from *T. formosana*. The specimen figured was raised from seeds collected by Messrs. ELWES AND

PRICE in Formosa. The plant is apparently not perfectly hardy in this country, but it would be suitable for growing in the cool greenhouse, and in warm districts would probably grow well out-of-doors. The flowers are purple with deeper spots on the upper surface and paler beneath.

STAFELIA LEENDERTZIAE, tab. 8,561.—The flowers of this species are very distinct, being bell-shaped, of a claret-purple colour, about 3 inches long and 2 inches across; in most members of the genus the corolla is flat or saucer-shaped. The plant illustrated was sent to Mr. W. E. LEDGER, of Wimbledon, by Mr. G. THORNCROFT, of Barberton, in the Transvaal.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The seventy-fifth anniversary festival dinner of the Gardeners' Royal Benevolent Institution will take place at the Hotel Metropole, Northumberland Avenue, on the 26th inst. The Right Hon. the Speaker, JAMES W. LOWTHER, Esq., who will preside at the dinner, makes an appeal for increased support in the following letter:—Speaker's House, S.W.—28th May, 1914.—Dear Sir,—I am to have the pleasure of presiding at the 75th anniversary dinner, in aid of the funds of the Gardeners' Royal Benevolent Institution, on the 26th June, at the Hotel Metropole, and I venture to ask for the kind assistance on that occasion of all lovers of flowers and of gardens. This National Horticultural Fund, since its foundation seventy-six years ago, has distributed nearly £150,000 amongst necessitous horticulturists and their widows. It is now affording permanent aid to 265 persons (150 men and 115 widows), at an annual cost of £4,840. In addition to this permanent charge upon its funds, it is the policy of the institution to provide immediate temporary assistance from separate funds in well authenticated cases of urgent distress. As regards the permanent charge, the assured income of the institution only amounts to £950 per annum, consequently there is a sum of about £4,000 which has to be made up annually from subscriptions and donations. In order to assist the institution in raising this amount, I invoke your generous aid, and should feel greatly favoured if you will give me the pleasure of your company on June 26.—I remain, yours very truly, JAMES W. LOWTHER.

FRUIT CROPS IN WÜRTTEMBERG AND FRANCE.—The Board of Agriculture and Fisheries is informed by H.M. Consul at Stuttgart that cold and wet weather during May did much damage to the fruit crop of Württemberg, all of which, except Pears, had previously promised well. Growers only expect to market a medium crop, Cherries especially will be much below previous estimate. An official report gives the condition of Apples on June 1 as 2.7, Pears as 3.4, and Grapes as 3.0 (2=good, 3=average, 4=poor). The Strawberry crop, which is just coming in, is reported as good. Quotations on the Stuttgart wholesale market are per cwt. Strawberries, 50s. to 85s.; Cherries, 18s. to 22s.; and green Gooseberries, 16s. to 20s. H.M. Consul-General at Paris reports (May 29) that the fruit crop in France is likely to be generally satisfactory as regards all kinds except Prunes, which will probably yield rather less than last year, and that prices will therefore probably be rather lower than in 1913. H.M. Vice-Consul at Honfleur reports (June 6) that in his district early Cherries are plentiful, and prospects are good for the later varieties. Good crops of table dessert Apples and early Pears, heavy crops of cider Apples, but only half a crop of Plums and Greengages, and very poor crops of late Pears, are expected.

ROYAL METEOROLOGICAL SOCIETY.—A meeting of the Royal Meteorological Society will be held at 70, Victoria Street, Westminster, on Wednesday, June 17, at 4.30 p.m. A paper on "The Rainfall of the Southern Pen-

ines" will be read by Mr. B. C. WALLIS, B.Sc., and one on "The Relation between Wind Direction and Rainfall," by Mr. H. J. BARTLETT.

PUBLICATIONS RECEIVED.—*Bulletins from the Purdue University Agricultural Experiment Station*: No. 164, Strawberries; No. 165, Tomato Investigations; No. 166, Commercial Fertilisers; No. 170, The Reclamation of an Unproductive Soil of the Kankalee Marsh Region; No. 171, The Vegetable Garden; No. 172, Soybeans and Cowpeas.—*Twenty-Sixth Annual Report of the Purdue University Agricultural Experiment Station*. HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE COMMON SWIFT MOTH (HEPIALUS LUPULINUS).—This moth, the caterpillar of which is so destructive to the roots of Paeonies and other fleshy roots in gardens, and even to the slender roots of other plants, is very difficult to catch with the net, as it flies swiftly just on a level with the low plants in the garden, vanishing at intervals. It also scatters its dark-coloured eggs loosely on the ground, so that it is almost impossible to see them. I was glad, therefore, to find a ready means of catching and killing the moths. Having left out overnight in the garden some emulsion of the insecticide Abol (with which I have been spraying the Apple trees) I found next morning twelve females of this species dead and floating in it. I therefore left it out a second night, and found eighteen next morning. In the evening I went out and found five more, but next morning only two out of the five were left. This I found was due to an inquisitive sparrow which I saw carrying off one of the moths. As the male ghost moth, *Hepialus humuli*, has white wings, I wondered whether the white colour of the emulsion attracted the female insects, but as the male of the *Hepialus lupulinus* is not white, but, on the contrary, darker than the female, I put out a white dish with water in it, and another white dish with milk in it, to see if they would be attracted to it, but they were not, whilst they still came to the Abol emulsion. It is probable, therefore, that there is something in the odour of the Abol that attracts them, as the males of other species of this genus have characteristic odours, that of *Hepialus hectus*, which feeds on Bracken roots, being likened to Pineapple, and that of the *Hepialus humuli* to the capric odour of the billy goat. In any case, the fact of the insect

being attracted and killed by the emulsion of Abol may be usefully placed on record. *E. M. Holmes, Ruthven, Sevenoaks.*

OBSERVATIONS OF MERODON FLY DURING ACT OF LAYING.—I have recently had the opportunity for the first time of seeing a Merodon fly laying an egg. I observed the operation in four cases, and in one, which I will describe, the observation was under the most favourable circumstances. The fly settled on the outside of the tuft of leaves from a "single" bulb about 2 inches from the ground, and turning almost immediately head downwards, proceeded to crawl down to the base. The soil, which had not been disturbed, had shrunk away from the leaves, leaving a fair-sized hole around them. On arriving at the level of the soil the fly went down with its head and about half its body into the hole. At this moment it seemed to be very agitated. It then withdrew its head, and, dropping from the leaves to the ground, it at once turned round and slipped into the hole tail first, with its back to the leaves, until only its head and its front legs, resting on the edge of the hole, were visible. Three or four seconds later I netted it and searched for the egg, but could find none on the leaves or neck of the bulb. The whole operation had taken about 20 to 25 seconds, and was performed with such unhesitating precision that it had every appearance of being normal. In the second case the ground had been hoed and the loose, dry soil had been drawn up against the leaves, thus filling in the holes, but the leaves swaying in the wind had formed shallow crater-form rings around each plant. The fly proceeded exactly as before, but it scabbled away the loose soil, both when it was prospecting head down and also as it settled itself in tail first. After catching it, I drew away the soil from the leaves and found the egg on the earth close to the neck of the bulb, but I may have detached it when drawing the soil away. In the third case the fly got partly around the leaves away from me, but it appeared to have its back to the leaves when in the hole: it certainly was not facing them. And in the fourth case the fly entered the hole tail first, but sideways—due, I think, to the shape of the hole. In neither of these two latter cases could I find the egg, and it was hardly to be expected, as striking with the net jars the leaves and surrounding soil. So it is impossible to say whether the eggs were attached to the leaves or simply dropped into the hole down beside the neck of the bulb. But if the fly does attach the egg it might be expected to face the leaves when laying, whereas the position with its back to the leaves would be more convenient for dropping it down the hole. If the grub does enter the bulb at the base, as there seems little doubt now that it does, it would seem to be more advantageous for the egg to be dropped as far down the hole as it would go, and the young grub on hatching would not then have so far to crawl. Also it would be safer from enemies, and would be more assured of moisture, which seems very essential to the young grub. I would have liked to have made further observations, but there have been no flies about for a week or more. This note is not written merely for the sake of recording a fact, though that is always to the good; but if it should be established that normally the egg is dropped into the hole, and not laid on the leaves, it is evident that the practice of keeping the soil loose and drawn up to the leaves, so filling in the holes, from the earliest time of the appearance of the fly would be of especial importance. *A. J. Bliss.*

THE LESSER NARCISSUS FLY.—Does Mr. A. J. Bliss seriously suggest that the meaning of the article in the *Journal of the Board of Agriculture*, read as a whole, resolves itself into this, that, having distinctly stated that the larvae of this fly do burrow into, and attack, the necks of the Narcissus bulbs, it is offered as a possible interpretation of the paragraph which Mr. Bliss quotes that under no circumstances do they do so; for, if under any circumstances they do so, then *pro tanto* the "scavenger" theory goes? Surely the writers in the journal are not so stupid as that. They have doubtless written on facts ascertained, although not thinking it necessary to set out all

these facts in detail. And we are not, therefore, told what were the whole conditions under which the flies of the second brood did not attack the bulbs; but, anyway, this throws no light on what, earlier in the season, the flies of the first brood may do. Mr. Bliss is mistaken in thinking that no facts have been brought forward to support the views of the *Journal of the Board of Agriculture*, while it is absolutely certain that from first to last no single fact has been adduced to affirmatively prove the "scavenger" theory. It rests wholly on surmise. And while it is, of course, true that were the "scavenger" theory to be sustained we might, to quote Mr. Bliss, "be put to considerable trouble that eventually might prove to have been unnecessary," on the other hand, should the other view be sustained where then will these persons who have not cared to take this trouble find themselves? Better a little trouble as an insurance against a somewhat serious risk. However I do not propose to waste further time in pursuing these arguments. As matters now stand it appears to be "Mr. Bliss versus The Board of Agriculture," and I am content to leave it at that, with heavy odds on the Board. *Charles E. Shea.*

OXALIS ADENOPHYLLA (see p. 400).—Referring to the note in your last issue, I may say that I have for two or three years grown this species (as also *O. enneaphylla*, white and rose), in a retaining limestone wall, and a few words on my experience may be useful to others. *O. enneaphylla* grows well and flowers moderately both in a north and a west aspect. The flowers expand fully and keep open even when the sun is obscured. I think, however, that the plants are not flowering so freely as formerly, and I should be glad to know if they should be lifted and broken up. If that is recommended, how and when should it be done? *O. enneaphylla* var. *rosea* is growing in a south-east aspect. Its foliage is smaller than in the type, and, moreover, it is brownish along the margins, as though not in perfect health. I have, however, noticed that these characters were present in all other plants that I have seen at Kew or elsewhere, and I should be glad to know whether readers can confirm this observation. My plant does not flower very freely, and the flowers are not so roseate this year as last. *O. adenophylla* occupies the same aspect as the last. It is as vigorous as, if not more vigorous than, *enneaphylla*, and much more floriferous. It is, however, far more sensitive to sunlight, and even on the brightest day its flowers close directly the sun's rays are withdrawn, as happens in my case before two o'clock. I see that some leaves are appearing in a joint of the wall half a foot from the main plant, a condition of things I have not noticed in the case of the other two forms. *William Somerville, Oxford.*

ANOPLANTHUS COCCINEUS (see p. 401).—*Anoplantus coccineus* flowered here in May last year. The seed had been received in 1910 from Tiffis, and was sown on the *Centaurea dealbata*, but nothing appeared. They again supplied me with seed in 1911, and again no result followed, and in 1912 I put out the *Centaurea* and the contents of the pot in the open ground, and forgot all about it until, going round the garden on May 25, 1913, I suddenly caught sight of the stem, looking like a stick of red sealing-wax. I am sorry to say it has not reappeared this summer. *A. C. Bartholomew, Park House, Reading.*

TRITONIA CROCATATA.—On a recent visit to Ingestre Gardens, Stafford, I had the pleasure of seeing an exceedingly fine batch of *Tritonia crocata*. Mr. E. Gilman, the head gardener, informed me that he found the plant invaluable for decorative purposes, either for cut flowers or pots. The colour is a beautiful shade of orange scarlet, very effective under artificial light. The plant resembles *Freesia refracta alba* in habit and growth, and can be cultivated on similar lines. The compost used by Mr. Gilman consists of fibrous loam and leaf-soil, with a little peat, silver sand, and mortar rubble. About seven or eight bulbs are placed in a 5-inch pot, and started in a cold frame. They are subsequently moved to a cold greenhouse, and placed near the roof-glass. A little liquid manure is applied when the spikes begin to push up, and

at this stage a little heat is occasionally given. A profusion of bloom is produced, which lasts from March until May. I feel sure that if this plant were better known it would be as popular as *Freesias*. *R. Greenfield.*

RIBES SANGUINEUM AUREUM BROCKLEBANKII.—As the raiser of this beautiful flowering shrub, may I be allowed to correct an error made by your reporter in his description of the plant on the occasion of its receiving an Award of Merit at the meeting of the R.H.S. on the 3rd inst.? He wrote on p. 402: "This is a pretty form of the dwarf species of *R. alpinum*, with foliage of an entirely bright yellow. Growing only 12 or 18 inches in height, it should prove useful to give a mass of bright colour in bedding." As it originated here as a sport on *Ribes sanguineum*, it will doubtless grow as high as the type, or nearly so. Specimens here are fully 3 feet high, and 4 or 5 feet through. It would have been higher, but, planted at the margin of the shrubbery border, it has been cut back annually. In your "Answers to Correspondents" column, p. 234, you were good enough to notice a flowering spray which I had sent to your office in these words: "The *Ribes sanguineum Brocklebankii* with yellow young foliage appears to be a very good shrub of its type. We have not seen it before." *Thomas Winkworth, Haughton Hall Gardens, Tarporley.*

SEVERING OF IVY STEMS.—In the issue for May 23, p. 352, on the explosive force of decayed Ivy, it is stated that Ivy will continue to grow if the stem is severed. I have never known a single instance where this has happened; I have known several cases where it has been tried, but it has always failed. I should be glad to know if any of your readers could give an instance of the stem of an Ivy having been completely severed, continuing to live throughout one summer. *H. G. B. Biddenden, Andover.*

THE ROYAL BOTANIC SOCIETY.—As an ardent enthusiast, who has been more or less in touch with horticulture, both at home and abroad, during the last thirty years, I am led to the opinion that your correspondent, Mr. Stuart R. Cope (see p. 401), is much too severe in his condemnation of the methods of a society which is making an honest endeavour to mend its ways. It is agreed that much of what he states has some sound basis for argument, still there is a deal that could be explained to account for the actions of those who manage this delightful oasis—anyway, at the present time. He expresses regret that the charter under which the Society's rights are held is not adhered to, but seems to forget that it is possible for constituted rules and regulations to require adjustment according to circumstances. He fails to grasp the fact, which must be clear to the most ordinary observer, that with the advance of knowledge in and about our Colonies there is not to-day that special demand for home-trained men and home-bred cultures, beyond what Kew can supply, that there was years ago when our possessions in every part of the world demanded everything they were in need of from this country, both in brains and plants, and in confirmation of this opinion am I not correct in stating that the present Director of Kew Gardens is himself, professionally, a product of India? I well remember, when young plants of Coffee, Tea, Cinchona, Rubber, and other economic and commercial crops were wanted, they were raised here and transported in Wardian cases, and I ask the question, is it absolutely necessary to make such regular shipments to-day? What could we now teach Ceylon about Tea and Coffee, the Malay States about Rubber, New Zealand about Grasses and Clovers, South Africa about Tobacco, Jamaica about the Sugar Cane, or Canada about Peas? The points Mr. Cope raises about the Royal Horticultural Society I am not in agreement with, as I contend that the true history of the real cause of the present unique position of this great and influential Society has yet to be written. *Donald McDonald.*

STOLEN FROM THE CHelsea SHOW.—It is unfortunate that, at the Chelsea Show, a theft occurred of plants sent over for certificates from French nurserymen of Roses not yet in com-

merce. That they were stolen by some expert for propagating purposes is evident, and the thief is probably the same person who stole from our stand during the night a guinea plant of Rose Mrs. Carnegie. May we express our sympathy with the firms who have suffered this loss at an English exhibition? *George Paul, Director, Paul and Son (Cheshunt).*

QUEEN WASPS AT TRING.—On the 5th inst. I received from Mr. R. C. Sanders, gardener at Halton House, Tring, a box of wasps that had been caught within a radius of two miles of Halton Gardens, between the second week in April and May 22 by men and boys on the estate, with a request that I would report whether they were all queens. I welcomed the opportunity of inspecting such a collection, because it would furnish evidence as to the relative numbers in which our British species occurred this year in that particular district. The investigation took me about five hours. On the whole the specimens were in excellent condition, and, with the exception of the mouldy ones and some badly discoloured, were easily identified. The collection purported to consist of 2,651 individuals, divided into two batches, viz., 1,725 caught by men and 926 by boys. There had obviously been a miscount, however, in both cases, for I found 1,707 in the first case and 901 in the second, a deficiency of 43 in all, which was not accounted for by the odd bodies, wings, heads, etc., which could not be included conveniently, because many of them undoubtedly belonged to specimens which I had already counted. In all such incomplete cases I counted them where identification was possible, and the result was as follows:—

	Caught by men.	Caught by boys.
Queens, <i>Vespa germanica</i> ...	1,056	568
<i>Vespa vulgaris</i>	276	135
<i>Vespa ruga</i>	235	133
<i>Vespa sylvestris</i>	137	61
<i>Vespa norvegica</i>	1	1
<i>Vespa austriaca</i>	—	—
Workers, <i>Vespa germanica</i> ...	1	—
<i>Vespa vulgaris</i>	1	—
A drone fly, <i>Eristalis pertinax</i>	—	3
	1,707	901

It will thus be seen that, with the exception of the rare cuckoo wasp, *V. austriaca* (*arborea*), and, of course, the hornet, all our British social wasps were represented, and that *Vespa germanica* was obviously by far the commonest species in the district this spring. Putting the average number of wasps, all sexes, produced in the nests which these 2,603 queens would have founded at 1,000—a very low figure in the case of *vulgaris* and *germanica*—we arrive at the total of nearly 3,000,000 wasps, which, barring accidents, would have emerged from those nests in the course of the season to do their beneficial work in reducing the number of flies and caterpillars of various kinds and their destructive work in attacking fruit later on. Let us hope that the balance will be in favour of the fruit; but it remains to be seen whether man will not be the sufferer in some other way. *C. Nicholson, Hale End, Chingford.*

SCOTLAND.

CRAIBSTONE ESTATE.—The Governors of the Aberdeen and North of Scotland College of Agriculture have paid to the Scott Trustees the purchase price of the estate of Craibstone, amounting to £18,000. The estate of Craibstone lies some six miles north of Aberdeen, and extends to over 760 acres, 474 being arable, 44 pasture, 218 woods and 27 waste land. The estate includes a roomy mansion, built some thirty years ago. There are some very fine specimens of Ash, Elm and Beech, and the potentialities of what may be done in experimental and research work in the domain of forestry are very great. The policies may be used as an arboretum, where specimens of trees and shrubs suited to the area embraced by the college could be grown. In all an area of something like 300 acres will be available for forestry purposes. The mansion is to be converted into a school of rural economy, something on the lines of the Munster Institute, Cork.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

JUNE 3.—*Present*: Mr. A. E. Bowles, M.A., F.E.S. (in the chair); Messrs. J. T. Bennett Pöe, W. Cuthbertson, F. J. Baker, W. Hales, J. Fraser, W. C. Worsdell, F. J. Chittenden (hon. sec.), and W. R. Dykes (visitor).
Fungus attack upon Nymphaea.—Mr. J. R. Ramsbottom reported as follows upon the fungus

burg, and, not realising he had the same fungus as Allescher, described it under the name *Ramularia nymphaea*; later as *Ovularia nymphaea*. Allescher afterwards pointed out that the fungi were identical, but that owing to having had old specimens he had been misled by the tearing of the epidermis of the host plant caused by the rapid growth of the fungus. He holds that *Ovularia* is the correct genus, and, of course, the first specific name, *nymphaeanum*, must stand. Judging from the specimens I have seen, *Ramularia*, rather than *Ovularia*, would seem to be the

FIG. 196.—IRIS LAEVIGATA ALBA.

R.H.S. Award of Merit, June 3, 1914 (see p. 42)

attack on foliage of *Nymphaea* shown at the last meeting:

"A leaf of *Nymphaea* sent to me by Mr. Bowles, and exhibited at the last meeting, showed two rows of large holes parallel to the midrib. An examination of the decayed tissues showed fungus spores, together with certain algae, diatoms, etc. The fungus proved to be one of the Hyphomycetes. It was first described by Allescher in 1895 as *Ploeosporium nymphaearum*. He had gathered it on living leaves of *Nymphaea alba*, *flava*, *odorata*, and *Nuphar luteum* in the Munich Botanic Garden. Bresadola had the fungus sent to him from Branden-

correct genus as the mature spores apparently become septate. I have found the fungus growing on wild Water Lilies at Wicken Fen, Cambridge, during the autumn of last year."

Rose malformed.—Mr. W. C. Worsdell said he had examined the Rose sent to the last meeting by Miss Collin, and had found the calyx normal, and all the petals save one changed into foliage-leaves. Proliferation into a second flower had occurred, the calyx of which merged imperceptibly in a complicated way into the virescent, superior carpels of the primary flower. This is an uncommon abnormality, as it is usually the calyx, not the corolla, which exhibits phyllo-

Malformed Schizanthus.—Mr. Worsdell also reported that he found virescence and proliferation of all the flowers of the inflorescence in the specimen shown at last meeting. Each flower has become changed into an inflorescence consisting of a number of minute rudimentary, axillary, virescent flowers, with no definite arrangement of their parts.

Gall on Daphne Mezereum.—Dr. Rendle reported that Mr. B. F. Cummings of the Natural History Museum had kindly examined the galls on *Daphne Mezereum* shown by Mr. W. E. Ledger at a previous meeting, and considered it not at all unlikely that they were the work of

cate was unanimously recommended for *Glaucidium palmatum* shown at the last meeting by Messrs. Perry, of Enfield.

Irises.—Mr. W. R. Dykes showed a series of Irises, species of the *I. sibirica* group, all characterised by a more or less hollow stem and beardless flowers. Among them were *I. Forrestii*, *I. Wilsonii*, and *I. chrysographes*, and the following hybrids: *I. × Zeta* (*sibirica* ♀ × *Wilsonii*), *I. × Epsilon* (*Bulleyana* ♀ × *Forrestii*), *I. × Gamma* (*Forrestii* × *chrysographes*). There were plants of the last form raised both ways, and all practically alike.

Iris tenax ♀ × *I. Wilsonii* (= *I. × Meta*)

Frost damage.—Mr. Chittenden showed Apple fruits about an inch in diameter which had been damaged by the severe frost on May 26 (at Wisley, 19° Fahr. on grass, 25° on post on the hill—probably lower in lower grounds). The flesh was in some cases only slightly-tinted brown about the vascular bundles, but in more severe attacks the cells had become greatly disorganised and the tissues broken. None of this damage was to be seen externally. The fruit on the trees on the hill had completely escaped damage, but that in the lower ground was very severely injured, although the fruits had not yet dropped.

Double Claytonia sibirica.—Mr. Chittenden also showed flowers of a double form of *Claytonia sibirica* from the Wisley Gardens, in which the doubling in some cases was not confined to the petals, but three or four pistils had been produced as well.

ROYAL METEOROLOGICAL.

MAY 20.—The first of the afternoon meetings of this society for the present session was held on Wednesday, the 20th inst., Mr. C. J. P. Cave, M.A., president, in the chair.

Mr. E. GOLD read a paper on "The Reduction of Barometer Readings in Absolute Units, and a new Form of Barometer Card." The Meteorological Office having now employed the C.G.S. units in their publications, this has necessitated the preparation of new tables for the reduction of the barometer readings and for the adjustment of the effect of difference between the standards of temperature 62° F. and 273° A.

Mr. A. HAMPTON BROWN also read a paper on "A Cuban Rain Record and its Application," in which he dealt with the rainfall records of the Belen College Observatory, Havana, for the period 1859 to 1912, and gave particulars of the monthly, yearly, and seasonal rainfall. The author has endeavoured to trace the connection between the wet season at Havana during May to October, and the precipitation in England, south-west and South Wales during the three months, January to March following, and he has found that from 1878 onwards, when the first reports for this country are available, an excess rainfall in Havana during May to October was generally followed by a deficient rainfall in England south-west at the beginning of the next year, and *vice versa*. For the eight years, 1888-1895, when the rainfall at Havana was continuously in excess, in England south-west the figures with one exception were the reverse. During the next five years, 1896-1900, there was a deficiency at the Cuban station, and, excepting 1897, an excess in this country. There were many years where the application failed, but the general continuance of the see-saw movement was so persistent that it could hardly be regarded as merely coincidental.

NATIONAL HARDY PLANT.

JUNE 4.—The annual show of this society was held at Vincent Square, on the day following the R.H.S. meeting and exhibition, and certain exhibits of hardy flowers of the previous show remained. These, with other trade exhibits, assisted in making the hall gay and attractive.

Entries for the competitive classes had been numerous, but a short time before the show many entrants found it necessary to withdraw. A large number of new plants were submitted for certificate, but only four novelties received awards. Twenty-five medals were awarded to groups and collections of hardy flowers.

CERTIFICATES OF MERIT.

Paeonia lobata.—This plant has been described as a dwarf variety of *P. officinalis*, but from a garden point of view it is distinct. The obovate, or nearly orbicular petals make a very attractive globular flower of coral red colour. The plants are dwarf, and, unlike some herbaceous Paeonies, are not overburdened with foliage. Shown by Mr. JAMES BOX.

Erigeron hybridus Asa Gray.—A very decorative variety producing cymes of flowers which have less stiff florets than usual; the colour is that known as old gold. Shown by Mr. B. LADHAMS.

FIG. 197.—HYBRID IRIS IOTA (*I. TENAX* × *I. PURDYI*): FLOWERS WHITE SHADED AND VEINED WITH LILAC.

R.H.S. Award of Merit, June 3, 1914 (see p. 402).

an early form of *Perrisia daphnes*, Kieff, a beetle larva.

Double Mangel.—Messrs. Camell and Sons, Loddon, Norwich, sent a double root of Mangel, two roots, one considerably larger than the other, being attached at about the widest part. The Committee thought it probable that the two had become grafted one on to the other during growth and following contact.

Double Daisy.—Mr. Wirsley sent heads of a double Daisy in which several capitula had become tightly pressed together, so that the whole head presented a very curious appearance.

Glaucidium palmatum.—A Botanical Certifi-

illustrated in a particularly striking degree the frequently-noted fact of the greater strength and vigour of a first cross over the parents. The flowers in this case had inherited a yellowish tinge from the pollen parent. *I. × Iota* (*tenax* ♀ × *Purdyi*) was also shown (see fig. 197). A peculiar colour variation in *Iris bracteata* (normally a yellow-flowered form) was also exhibited with flowers of a purplish tint, and the beautiful *I. laevigata* (see fig. 196) so often confused with *I. Kaempferi*.

A Certificate of Appreciation was unanimously recommended to Mr. Dykes for his work in raising these Irises.

Campanula Hohneckeri.—This exceedingly floriferous plant is said to be a perennial, but it is advisable to sow seeds annually, as the plants bloom so freely that it sometimes kills them. The inflorescences of sky-blue flowers are about 18 inches high. Shown by Messrs. PIPER AND SONS.

Erysimum lunifolium.—A dainty little "Fairy Wallflower." The petals are attractively crumpled, and their colour is a soft shade of lavender. Shown by Mr. C. ELLIOTT.

COMPETITIVE CLASSES.

The only exhibit of a rock garden, arranged on a ground space of 72 superficial feet, although flat, was very pretty and attractive, and worthy of the 1st prize. The exhibitors were Messrs. W. ARTINDALE AND SON, Sheffield.

The two competitors in the class for a collection of hardy herbaceous perennials, arranged on a floor space of 15 feet by 8 feet, availed themselves of the licence allowed by the schedule to employ cut blooms chiefly, and they made very attractive displays. Messrs. G. and A. CLARK, LTD., Dover, included a large amount of bloom without giving the slightest suggestion of crowding, and all their flowers were exceedingly well-grown specimens. Spikes of *Dictamnus* and *Delphinium* were magnificent. Several hybrid *Verbascums* attracted attention, and of these V. A. M. Burnie (salmon buff), V. *Ivanhoe* (terra-cotta), and V. hybridum (bright yellow), were graceful and charming. Besides good bunches of the bright red *Geum Mrs. Bradshaw*, there were equally fine bunches of the rarer *Geum John Bradshaw*, which bears golden-buff flowers, and blooms again in the autumn. (Small Gold Medal.) Messrs. ARTINDALE AND SONS, Sheffield, had especially good herbaceous *Pyrethrums*, of which J. Kelway and Mr. B. Brown, both bearing bright red flowers, were very attractive varieties. *Eremurus robustus*, *E. himalaicus*, *E. Elwesianus*, *Lupinus roseus*, and *Papaver orientalis Garibaldii* were also exceptionally good. (Silver-gilt Medal.)

Mr. W. MILLER, Wisbech, was awarded the 1st prize for a collection of *Pyrethrums*, which included many good varieties.

Mr. R. MORRIS, Grange Dene, Woodside Park, London, who showed good vases of *Papaver orientalis Crimped Beauty*, *Iris germanica Walmer*, *Inula glandulosa superba* and *Aquilegia hybrids*, won the 1st prize in the class for four vases of distinct hardy herbaceous flowers; and Mr. F. BOUSKELL, Market Bosworth, Nuneaton, showing especially good *Lupinus*, was placed 2nd.

Mr. F. BOUSKELL won the 1st prize offered for one vase of any one kind of herbaceous flower with a pretty arrangement of *Anthericum Liliago algerense*; 2nd, Mr. F. BAILEY, with pink *Lupinus*.

Mr. E. MUDGE, Willesden, who placed various German Irises in rather large blue bowls, was awarded the 1st prize for table decorations; and Mr. E. G. QUICK was awarded the 2nd prize for an arrangement of Iceland Poppies and grasses.

NON-COMPETITIVE EXHIBITS.

Messrs. J. PIPER AND SONS, Bayswater, London, included many Alpines in the large exhibit they arranged, especially for this show. Such plants as *Helichrysum frigidum*, *Pratia arenaica*, *Scutellaria indica*, *Campanula glomerata* *Maive Queen*, *Silene Hookeri*, *Primula sikkimensis*, and various *Cypripedium* are typical examples of the rock garden exhibits in Messrs. PIPER'S splendid contribution, which also included good plants of *Lavatera Olbia*. (Large Gold Medal.)

Mr. JAMES BOX, Hayward's Heath, added to his exhibit of the previous day several vases of the charming *Paeonia lobata*, which received a Certificate of Merit, two large stands of the very fragrant *Paeonia albiflora grandiflora*, and a large number of *Pyrethrums*, *Lupinus* and *Primula sikkimensis*. (Large Gold Medal.)

Messrs. DOBBIE AND CO., Edinburgh, replaced the Sweet Peas, which we admired on the previous day, but which having been grown under glass, were not admissible, by very many vases of *Aquilegias* of an excellent strain. The magnificent *Antirrhinums*, however, were still on view, and again received admiration. (Large Gold Medal.)

Messrs. J. KELWAY AND SONS, Langport, Somerset, were awarded a Large Gold Medal for their exhibit of herbaceous *Paeonies* and *Pyrethrums*; and Messrs. BARR AND SONS,

Covent Garden, London, received a small Gold Medal for their collection of *Lupinus polyphyllus* varieties. Messrs. H. B. MAY AND SONS, Upper Edmonton, showed many valuable hardy Ferns, of which *Osmunda palustris congesta*, *O. regalis cristata*, *Athyrium Victoriae*, and *A. gemmatum tricolor* are a few examples. (Small Gold Medal.)

Messrs. HARKNESS AND SONS, Bedale, were awarded a Silver-gilt Medal for a rock garden. The principal plants were *Primula Bulleyana*, *P. Veitchii*, *Hutchinsia alpina*, *Incarvillea Delavayi*, *Saxifraga Cotyledon*, and *Violas*.

Messrs. WM. CUTBUSH AND SONS, Highgate, planted a rock garden with such plants as *Dianthus Napoleon III.*, *Ramondia pyrenaica*, and *Cypripedium pubescens*, and also showed many excellent border flowers. (Small Gold Medal.)

Messrs. W. and J. BROWN, Peterborough, included many stately spikes of *Eremurus*, and good plants of *Salvia Tenorii* in a fine collection of hardy flowers. (Small Gold Medal.)

Mr. F. BOUSKELL, Market Bosworth, Nuneaton, arranged a group of choice *Lupinus*, *Paeonies*, *Irises* and *Papavers*. (Silver-gilt Medal.)

Messrs. SUTTON AND SONS, Reading, displayed an excellent strain of long-spurred *Aquilegias* in many beautiful colours. (Silver-gilt Medal.)

Messrs. J. VEITCH AND SONS, Chelsea, included splendid examples of *Primula capitata*, *P. sikkimensis*, *P. unique*, and other *Primulas* in a group of choice border plants. (Silver-gilt Medal.)

Silver-gilt Medals were awarded to Messrs. T. S. WARE, LTD., Feltham; Messrs. PHILLIPS AND TAYLOR, Bracknell, Berks; Messrs. J. WATERER, SONS, AND CRISP, Liverpool Street Arcade, London; and Mr. AMOS PERRY, Enfield, for the collections of hardy plants, which were noted in the report of the previous day's show. Silver Medals were similarly awarded to Messrs. R. H. BATH, LTD., Wisbech; the Misses HOPKINS, Shepperton-on-Thames; Mr. C. ELLIOTT, Stevenage; Mr. J. REUTHE, Keston, Kent; and to Messrs. B. LADHAMS, LTD., Southampton.

Messrs. REAMSBOTTOM AND CO., Geashill, King's County, brought a collection of beautiful *Anemones*. (Silver Medal.)

Messrs. ROBINSON BROS., LTD., West Bromwich, exhibited *Carmona Plant Food*, and various insecticides and fungicides, and demonstrated the handiness and efficacy of their Alpha-sprayers, which were displayed in a variety of sizes and qualities.

Messrs. A. E. WHITE, LTD., Paddock Wood, Kent, exhibited "Abol" insecticides, and their very useful "Abol" knapsack hand sprayers.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JUNE 8.—The monthly committee meeting was held at the R.H.S. Hall on the 8th inst. Mr. C. H. CURTIS presided. A member was allowed to withdraw £30 from his deposit account, still leaving £62 to his credit; two other members withdrew the sums of £4 and £2 8s. respectively. Two members were assisted from the Distress Fund, and the sick pay on the ordinary side amounted to £60 13s. 10d., and on the State Section £24 7s.; maternity claims being £13 10s. Two new members were elected, and the Commissioner's scheme for the reduction of benefits for insured persons, who are in arrears, was brought forward.

SCOTTISH HORTICULTURAL.

JUNE 2.—The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on the 2nd inst. Mr. KING, the president, was in the chair, and there was an attendance of sixty members.

The evening was an open one, and the following questions were discussed:—(1) In judging Sweet Peas, should scent count? (2) What is the cause of waving, frilling, etc., in flowers? The general impression was that it would be out of the question to ask judges to take account of scent in the case of Sweet Peas on the exhibition table, but that in the case of new varieties submitted for certificates it should be given due consideration. No satisfactory reply was forthcoming as to the cause of waving and frilling of flowers.

Mr. J. W. SCARLETT mentioned that the purple-topped Milan Turnip formed its bulbs sooner, and consequently could be got earlier, when it was grown from seed produced by plants which had themselves been grown from seed sown in April, and which flowered and fruited the same season, than from seed produced in the following season from later sown plants.

The exhibits were:—Seedling hybrid *Aquilegias*, exhibited by Mrs. SCOTT-ELLIOTT, Teviot Lodge, Hawick (awarded a Certificate of Merit for strain); and *Rosa lutescens* (*R. pimpinellifolia* × *R. lutea*), exhibited by Mr. GEO. W. TAYLOR.

ROYAL HORTICULTURAL OF VICTORIA.

EXHIBITION AT MELBOURNE.

APRIL 22, 23.—The autumn show of this Australian Society was held in the Melbourne Town Hall on these dates. The show was preceded by a very squally day, and many outdoor flowers were missing from the tables, but flowers grown in shelter, such as *Chrysanthemums* and *Begonias*, were in excellent condition. Owing, however, to an exceptionally dry season, many flowers, and in particular *Gladioli*, were much below the usual standard of quality, and the competition was not so good as in former years. Vegetables were an improvement on those shown last year, whilst fruit was finely coloured. Roses were on the poor side; the 1st prize was awarded to the following twelve varieties:—Mrs. Myles Kennedy, Lady Ashtown, Laurent Carle, Mme. M. Souperet, Lyons Rose, Maman Cochet, White Maman Cochet, Mrs. W. J. Grant (here known as Belle Siebrecht), Frau Karl Druschki, M. Constant Souperet, Niphetos, and Duchess of Portland. Amongst the fine exhibits of *Chrysanthemums*, the twelve varieties staged by Mr. W. J. POCKETT, JUNR., won the Challenge Cup, the varieties being Queen Mary, R. M. Buittenton, Edith Buittenton, Gladys Blackburn, Mrs. W. A. Reid, Reginakl Vallis, Miss E. King (yellow), Kara Dow (bronze), G. W. Pook, J. 47 and J. 10; the last, an unnamed seedling, was selected as the champion bloom in the show. It is a splendid white variety, with long, drooping florets, yet having the centre perfectly covered; every bloom in this exhibit measured 9 to 10 inches across. The best six *Cactus Dahlias* were Red Admiral, Mrs. Brundrett, H. H. Thomas, Snowdon, Golden Ware, and Mrs. Upham, all the blooms being of fair size for so late in the season. Show Dahlias were only of moderate quality. A guinea offered as the 1st prize for six hardy herbaceous perennials brought forth one exhibit only. It was awarded the prize, and consisted of *Gaillardia*, *Phlox decussata*, *Delphinium* var., *Helenium autumnale superbum*, a variety of *Pentstemon* and *Aster ericoides*.

Non-competitive exhibits were numerous, and included fine *Chrysanthemums* in pots; a superb, unnamed specimen of *Polypodium*, with fronds 5 feet long and 18 inches across; a choice collection of *Nerines*, including the varieties *Lady Carrington*, *N. alba*, *Lady Llewellyn* (indistinguishable from *N. splendens*), *N. amabilis*, *N. O'Brienii*, *Salmon Queen*, and *Meadowbankii* (the last apparently synonymous with *N. Fothergillii*). There were also exhibits of nine varieties of winter-flowering Sweet Peas; two exhibits of *Gladioli*, representing well over 150 varieties, notable sorts being *Glory of Noordwijk* (a fine pale-yellow, rather small flower), *Europa* (a white bloom, with faint lilac stripes, also small in size), *Empress of India* (dark wine-purple or maroon), *Halley* (a very pretty pale salmon-pink variety, with weak stems, but large and well-placed flowers), and *Niagara* (a good spike of creamy pink). As usual, the Curator of the Melbourne Botanic Gardens exhibited a magnificent collection, comprising *Collerette*, *Paeony*, *Cactus*, *Show* and *Single Dahlias*, interspersed with *Chrysanthemums* and *Azaleas*, *Callistemon lanceolatus*, *Camellia Sasanqua*, *Hoheria populnea*, *Heptapleurum longifolium*, *Bougainvillea glabra*, *Bouvardia leiantha*, *Stenocarpus sinuata*, *Erica melanthera*, *Protea mellifera alba*, and other interesting plants. *Gilbert Errey, Victoria.*

Obituary.

JAMES SIMMONS.—We learn with regret of the death, on May 16, of Mr. James Simmons, for thirty-five years gardener at Carlew, Cornwall, aged sixty-two years. Mr. Simmons was a native of Devonshire, and was appointed gardener at Carlew when twenty-seven years of age. The place afforded scope for his abilities as a gardener; he raised many hundreds of seedling Himalayan Rhododendrons, and other tender subjects. He leaves a widow, one son and one daughter.

LAW NOTE.

INTENSIVE GARDENING IN URBAN DISTRICTS.

IN the Chancery Division recently, before Mr Justice Warrington, evidence was given in the action by Mr. and Mrs. John Otway Percy Bland, of the Clock House, Upper Halliford, near Shepperton, to restrain Mr. Henry Stanton Yates, a "French" gardener, from stacking manure so as to interfere with the health and comfort of plaintiffs.

Mr. Yates, the defendant, said in cross-examination that he used about 1,500 tons of manure a year in the making of his beds for intensive gardening. He did not realise that any nuisance was caused.

Mr. Justice Warrington stated that plaintiffs alleged that they had been compelled to put up wire blinds to exclude the flies attracted by the manure, and were never able to have windows open properly. Defendant replied that he had been at his foreman's cottage in the garden and did not suffer from flies.

Plaintiff's counsel said that for three years defendant had promised to do something to minimise the nuisance, but had claimed the right to stack manure on his land because he was using it in the ordinary course of his business.

Mr. Yates replied that he put the manure behind the shed and raised a corrugated iron fence, and, after consulting the sanitary authorities of Sunbury, placing a screen on top of the shed, promising to remove the manure 14 yards further off, making another road, and doing all that at his own expense, he thought he had done everything in his power.

Mr. Coles, sanitary inspector for Sunbury, said he received a written complaint from plaintiff on October 13 last as to the heap of manure. He visited the garden and made certain suggestions to the defendant. These he reported to the medical officer of health, who approved of them, and they were carried out by Mr. Yates.

Mr. John Weathers (instructor on horticulture to the Middlesex County Council) said a manure heap as managed by Mr. Yates gave off a very slight smell of ammonia—an agreeable smell to him, at any rate. He really did not notice any flies about. He was rather susceptible to flies, and he thought he would have noticed if any were about.

Mr. Ernest Edward Austen (assistant in the section of Entomology, Natural History Department of the British Museum), said that at the request of plaintiff's solicitors he visited their property with Sir Ronald Ross on May 18 and made a report on his investigations. He had no interest in this case except as a scientist. In the garden of Mr. Bland's house he saw a small number of flies of various sorts, but he did not see a single house-fly. He did not expect to find any, as the house-fly was attached to houses and human dwellings, such as military camps. In the drawing-room he tried to find house-flies and discovered only one. That was the only house-fly he found during his visit. There was a swarm of flies under the glass in the porch. They belonged to three or four species, but there was not a single house-fly. These, he expected, would come from decaying animal or vegetable matter. He experienced no discomfort from flies, either in the garden or in the house, and he noticed no smell. Cross-examined, he admitted that the presence of a large heap of manure in a state of fermentation would be likely to cause a plague of flies.

His lordship, without calling on counsel for the plaintiffs, gave judgment. He said it was with some reluctance (because it might interfere with a profitable and good industry) that he must grant an injunction restraining defendant from depositing or stacking on his land adjoining plaintiffs' premises manure so as, by reason of offensive smell or the breeding and collection of flies, to occasion a nuisance to plaintiffs. He did not intend to stop defendant's garden, but only wished to prevent his carrying on his operations so as to occasion a nuisance to plaintiffs. Defendant must pay the costs of the action.

DEBATING SOCIETIES.

BATH GARDENERS'.—At the meeting of this society, held on the 13th ult., Mr. Halliburton read a paper on "The Rock Garden." Great care, remarked the lecturer, should be taken in the construction of the rockery, and limestone was a very good material to use as boulders.

BRITISH GARDENERS' (Watford Branch).—A meeting of the Watford branch of the B.G.A. was held on the 21st ult., Mr. W. R. Phillips presiding. There was a good attendance. Mr. Harding gave an address on "Watford's Past and Future."

BRISTOL AND DISTRICT GARDENERS'.—The opening meeting of the summer session of this association was held on the 28th ult., Mr. K. Jennings presiding. Mr. Cyril Harding delivered an address on "The Aims and Objects of the British Gardeners' Association." The prizes offered by Mr. Barnard, for a brace of Cucumbers, were won by Mr. Miles, Mr. Ayres, and Mr. Thoday, in this order.

MACMILLAN'S Monthly List of New Books for June, 1914.

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

Mr. H. Wilson, for the past 18 months Foreman at Wortley Hall, Sheffield, as Gardener to R. A. OSWALD, Esq., Auchincruive, Ayr. [Thanks for 2s. for R.G.O.F. box.—Eds.]

Mr. C. J. White, for the past 6 months Foreman at Heywood, Ballinakill, Queen's Co., Ireland, and previously at Muckross Abbey, Killybegny, as Gardener to Lady Gordon, Arden, Co. Kerry.

Mr. A. Perry, for the past 12 years Gardener to Col. D. L. ANSTRUTHER, Tendring Hall, Stoke-by-Nayland, Colchester, as Gardener to the Hon. HENRY COVENTRY, of the same address. [Thanks for 2s. for R.G.O.F. Box.—Eds.]

Mr. F. Tebbetts, for the past 7 years General Foreman at Cotton House, Rugby, as Gardener to Sir A. E. FELLOWES, K.C.V.O., Honingham Hall, Norwich.

Mr. D. B. Whitelaw, for 2½ years Gardener to W. D. RUSSELL, Esq., Maulside House, Glengarnock, and previously foreman at Bothwell Castle, Lanarkshire, and Buchanan Castle, Stirlingshire, as Gardener to C. F. K. MAINWARING, Esq., Oteley Hall, Ellesmere, Shropshire.

Mr. W. Wyatt, for the past 5 years Second Gardener at Swanston House, Whitechurch, Reading, as Gardener to C. S. PERSE-DUNCOMBE, Esq., Broadwell Hill, Moreton in the Marsh, Gloucestershire.

TRADE NOTE.

MESSRS. KELWAY AND SON.

WE are informed by Messrs. Kelway and Son, Langport, that they have relinquished their retail seed business so far as British orders are concerned. Their seeds may be obtained, however, by retail buyers through the trade. The retail business in plants will be carried on as before.

MARKETS.

COVENT GARDEN, June 10.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

		— French	1 3—
		Smilax, per bunch of 6 trails	1 0-1 3

REMARKS.—Prices generally are much lower, and business more steady. There are many varieties of Carnations on sale, and the blooms of these are much finer than they have been. The most noticeable varieties are Enchantress and Rose Pink Enchantress; many people, however, prefer the Winsor variety, as, although the flowers are smaller, they are similar in colour and last longer. Other popular varieties are Mayday, Carola, Triumph, Empire Day, British Queen, Lady Northcliffe, Mrs. Ward, Mrs. H. Burnett, White Perfection, White Enchantress, Mikado, and Lady Alington. Britannia and Scarlet Glow are preferred to Beacon, which does not last so well in warm weather. White Carnations are not plentiful, and they are more valuable than coloured sorts. The price of Lilium Harrisii (longifolium) is lower than it has been this season, and blooms of L. speciosum rubrum are arriving in a much better condition. Gladiolus The Bride is more plentiful and selling more freely. Peach Blossom, Akermannii,

No Plus Ultra, and Brilliant are the leading coloured varieties offered now. There are also good supplies of white, pink, and blue Cornflowers, Iceland Poppies, white and pink Gypsophila, double and single Pyrethrum, and Pinks Her Majesty and Mrs. Sinkins. The Rose trade is very slack, the favourite varieties being Mme. Abel Chatenay, Liberty, Richmond, and Frau Karl Druschki. Amongst foliage Asparagus Sprenger, A. plumosus, Smilax, Adiantum Fern, Carnation foliage, and French Myrtle are all more plentiful; a few bunches of Eulalia Grass are on sale.

REMARKS.—There is nothing new to record in this department. The chief business is in flowering plants. Ericas are nearly over; Crassulas are coming to hand in a splendid condition. The Fern and Palm trade is only moderate. Ferns, and especially those in 5-inch (48's) pots, are only of a medium quality.

REMARKS.—Shipments from Australia this week amounted to about 16,000 packages, consisting of Apples, Pears, and Grapes. The supply of Strawberries is unusually heavy for this season of the year. There is only a limited number of Nectarines, but Peaches are very plentiful. There has been a shorter supply of Green Figs; Melons continue plentiful, and there are ample supplies of black and white Grapes. The following Continental fruits are available: Black and Red Currants, Peaches, Nuts, Cherries, Apricots, Plums, Green Almonds, and Canteloupe Melons. Larger supplies of green Gooseberries are arriving, but Tomatoes and Cucumbers are not plentiful.—E. H. R., Covent Garden, June 10, 1914.

REMARKS.—Trade in old Potatoes is fairly good, but stocks are almost exhausted; their prices are satisfactory. New Potatoes have advanced in value, and this has checked sales, but it is expected that they will be cheaper this week-end.—E. J. Newborn, Covent Garden and St. Pancras, June 11, 1914.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending June 6, is furnished from the Meteorological Office:—

June 9, 1914.
Remarks on Wind and Weather.—At the beginning of the week the passage eastwards of a "V"-shaped depression across Scotland and the upper part of the North Sea was accompanied by westerly to north-westerly winds, reaching the force of a gale on some of the more exposed parts of our North and North West coasts. A subsequent veering to the northward was experienced, with a general fall of temperature, but towards the middle of the week, when a large anticyclone extended over the country from the Atlantic, the wind fell light and the thermometer rose in most districts to about its average level for the time of year. Towards the close of the period, the gradual extension of a well marked depression from the Icelandic region was associated with a freshening current of air from the west or north-west, the sky became very cloudy, and temperature showed a tendency to fall. A sharp ground frost occurred at some inland stations in North Britain on the night of May 31, and again on the night of June 2.

THE WEATHER IN WEST HERTS.

Week ending June 10, 1914.
A Most Welcome Rain.—The first day of the week proved warm for the time of year, but since then unseasonably low temperatures have prevailed. The nights were, however, as a rule not so unseasonably cold as the days. On the coldest night the exposed thermometer registered 2° of frost. The ground is at the present time 2° colder than is seasonable, both at 1 foot and 2 feet deep. Rain has fallen on each of the last five days, and to the total depth of nearly an inch. Previous to that, for nearly a month there had been very little rain. This is shown by the soil gauges, through neither of which had there been any percolation of rainwater at all until the last day of the past week, or for nearly a month. The sun shone on an average for 5½ hours a day, which is half an hour a day short of the average duration for the same period in June. The first two days were very bright,

the sun shining respectively for 1½ and 11 hours. Calms and light airs alone prevailed, the direction of these light airs being almost exclusively some northerly point of the compass. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 4 per cent.

MAY.

Dry, and on the whole of about seasonable temperature.—Taken as a whole, this was a May of about average temperature. There was a warm period in the middle of the month lasting ten days, followed by a cold period lasting five days. On the warmest day the temperature in the thermometer screen rose to 77°, and on the coldest night the thermometer exposed on the lawn registered 11° of frost. The extreme maximum temperature was nothing very unusual, but the lowest night temperature (11° of frost) was, with four exceptions, the lowest reading recorded here in May during the last twenty-nine years. Rain fell on thirteen days, but to the total depth of only 1¼ inches, which is ¾ inch short of the average quantity for the month. This was the driest May for eight years. Of the total quantity three-fourths was deposited on the first eleven days of the month. The sun shone on an average for 6½ hours a day, or about the average duration for May. The winds were as a rule light, and more particularly was this the case during the latter half of the month. In no hour did the mean velocity exceed sixteen miles—direction west. The average amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by 1 per cent.—E. M., Berkhamsted.

THE ROYAL COUNTIES' AGRICULTURAL SOCIETY.

At the Portsmouth meeting of the Royal Counties' Agricultural Society, which opened on Wednesday last, Messrs. SUTTON AND SONS exhibited 40 varieties of vegetables, specimens of such root crops as Mangels, Swedes and Turnips, also Gloxinias, Begonias, Calceolarias, Clarkias and other flowers.

ANSWERS TO CORRESPONDENTS.

"There are few gardeners, and still fewer amateurs, who do not on occasion require immediate information upon various points of practice. But either from an unwillingness to inquire, or from not knowing of whom to make the inquiry, they too often fail to obtain the information they are in want of. And let no one be alarmed lest his questions should appear trifling, or those of a person ignorant of that which he ought to know. He is the wisest man who is conscious of his ignorance; for how little do the wisest really know!—except that they know little. If one man is unacquainted with a fact, however common, it is probable that hundreds of others in the same position as himself are equally in want of similar information. To ask a question, then, is to consult the good of others as well as of one's self."—Gardeners' Chronicle, No. 1, Vol. I., January 2, 1911.

CYANIDING A CARNATION HOUSE: F. Erber, Germany. You do not state what insect is attacking your Carnations, but presumably it is aphid, which may be killed without the slightest fear of injuring the foliage by using cyanide at the following strength per 1,000 cubic feet contents:—½ oz. sodium cyanide, ½ oz. pure sulphuric acid, ½ oz. water.

MANURE FOR PERPETUAL-FLOWERING CARNATIONS: Teacher. Perpetual-flowering Carnations intended to be grown the whole twelve months of the year in pots must be fed, and feeding should be commenced directly the plant is established in its flowering-pot. Liquid stimulant made from fowl manure and soot is suitable in the spring and summer months and will give increased size and lustre to the flowers. Put half a bushel of the materials in a bag and place the bag in a 36-gallon cask of water, allowing it to stand for 24 hours, then dilute at the rate of half a pint to 2 gallons of water. The manure water should not be applied more than once a week. It is not recommended to use strong chemical fertilisers, as these eventually undermine the constitution of the plant, but you may employ one of the special fertilisers for Carnations.

NAMES OF PLANTS: T. W. A variety of Coleus known as Paisley.—W. Payne. 1, Andromeda floribunda; 2, Solanum crispum.—E. H. Ekins. On another occasion send only six specimens at one time. 1, Fagus sylvatica heterophylla; 2, Berberis japonica; 3, Skimmia japonica; 4, specimen too poor to identify; 5, Asparagus plumosus; 6, Adiantum formosum; 7, Selaginella Kraussiana; 8, S. Braunii; 9, Adiantum sp.; 10, Zebrina pendula; 11, Iris sibirica orientalis; 12, Hornimium pyrenaicum; 13, Sedum spatulifolium; 14, Sedum rupestre;

FRUIT PROSPECTS IN EASTERN COUNTIES.

Special Investigations by "SOUTHERN GROWER."

I.—CAMBRIDGESHIRE.

A MOTOR-CAR tour through the principal fruit districts of Cambridgeshire, Suffolk and Norfolk has enabled me to form estimates of the various fruit crops. In all the districts it was found that a great deal of damage had been done by the May frosts, and in some by a like visitation which occurred at Eastertide. The injury, however, was curiously partial. Strawberries, Pears, Plums, and Currants were most damaged. Raspberries to a less extent, and Cherries very little. Reports indicated that early Apples were the chief sufferers. As a matter of fact, however, the early varieties of this fruit are those which show the best crops, most late sorts, and particularly Lane's Prince Albert and Bramley's Seedling, being extremely short of fruit in most places, mainly because they bore great crops last year.

THE WISBECH DISTRICT.

A Suffolk fruit-grower who accompanied me had obtained the kindly assistance of a Wisbech grower, Mr. Miller, who devoted a day to showing us many of the principal orchards in the district, which he knows thoroughly, as well as some small ones, and whose stores of information as to details of the local fruit industry were freely com-

municated to us. No certain estimate of the area under fruit in the district could be given by him; but the Agricultural Returns make the extent in the Isle of Ely, in which the town is situated, 6,133 acres, and the greater part of this area must be in or quite near to Wisbech. The official tables also credit Wisbech alone with 8,187 acres of crops other than Corn, Potatos, Roots and Grass, and, allowing for Clover, mixed forage crops, various culinary vegetables, Mustard and seed crops, a large proportion, perhaps over 5,000 acres, may be allowed for fruit. The soil is a rich and free-working alluvial deposit of great depth, in many places 12ft. to 13ft., over a subsoil of sand—in some cases running sand. The soil is remarkably rich in nitrogen, but devoid of lime and deficient in phosphates and potash. It is admirable for Potatos, which are extensively grown; and, judging from the sizes of old trees, it must be well suited to Apples and Pears, while Plums, Strawberries, Raspberries and Gooseberries grow well or fairly in it, but not Cherries or Black Currants—at least, though Black Currants may grow enough wood in it, they do not fruit well. Very few Cherry trees are to be seen.

The first impression derived from an off-hand inspection of the orchards was that they were extremely overcrowded, and this was confirmed with respect to many that were more closely examined, though not in all cases. Moreover, it must be said with reluctance that there is a great deal of slovenly fruit culture in Wisbech. Pruning is sadly neglected, as shown not only by the interlocking of branches on individual trees and that of the branches of one tree with those of its neighbours, but also by great quantities of dead wood sticking up on trees liable to canker. Quantity rather than quality of fruit is obviously the main object of most growers, to sell by the ton, as fruit is mainly sold in the district, to a great extent long before it is gathered.

The high value of land accounts to a great extent for the overcrowded condition of many of the orchards. Unplanted land, we were informed, sold at £100 an acre commonly, and planted land up to £200, while rents of planted land are £8 to £10 an acre. In the effort to get the utmost produce off such dear land, trees are planted at half the proper distance in many cases, and those which were intended, perhaps, as "fillers," are left to stand. And then there is bush fruit, and for a time in many cases there are Strawberries or bulbs under the thickly planted trees. Probably more value would be obtained from a given area if half the trees in the overcrowded orchards were dug up.

Degrees of cleanliness in the orchards vary greatly, some being kept fairly or scrupulously free from weeds, and others not. Weeds have not much chance of growing on some of the most densely shaded ground, and while the trees are young, and Strawberries are grown among them, the land is kept well cultivated and hoed as a rule. In one oldish orchard that was seen neither pruning, spraying, nor

hoeing had been done. The Gooseberries under the interlocking trees were almost fruitless, weeds among them being thick and as tall as the bushes, while the trees, we were told, never yield any considerable quantity of fruit. This is an exceptionally bad example of neglect; but a few other cases are only less discreditable.

WELL-MANAGED ORCHARDS.

The preceding remarks do not apply to the orchards of Messrs. R. H. Bath and Co., or to some others which were inspected. Indeed, many fruit gardens, large and small, are in all respects well managed.

Messrs. Bath have 400 acres of land under flowers, fruit and vegetables. The fruit includes about 120 acres of Apples, forty acres of Plums, fifty acres of Strawberries, forty acres of Raspberries, and a large acreage of Gooseberries. As in most cases trees and small fruit are grown together, the total area under fruit is not to be got at precisely from these figures. These orchards are admirably managed, and in viewing them we had the advantage of the company of the practical manager of the fruit and vegetable divisions of the estate. From him we learnt that Bramley's Seedling, Allington Pippin, Early Victoria, and Lane's Prince Albert are the Apples most extensively grown. Others more or less largely grown are Worcester Pearmain, Norfolk Beauty, James Grieve, Beauty of Bath, Grenadier and Duchess of Oldenberg. The last crops well, but sells badly. Worcester Pearmain does not flourish, while Norfolk Beauty and James Grieve give great satisfaction. We saw more fruit on some of the Bramley trees than in any other orchard visited during our tour, but very little on others. In most districts this variety is very poorly fruited this year, having produced a heavy crop in 1913. Lane's Prince Albert is nearly fruitless in this as in other orchards. Allington and Early Victoria, great favourites at Wisbech, bear good crops this season in Messrs. Bath's and other orchards. Other Apples cropped well are James Grieve, Grenadier, Beauty of Bath and Norfolk Beauty. Cox's Orange Pippin does not flourish at Wisbech, and is hardly grown at all. On the whole, the Apple crop is better in Messrs. Bath's orchards than in any other visited in the district.

The principal Plums are Victoria and Prince of Wales. There are a few Czars, Bush Plums, and Monarchs, but no Early Rivers. The last variety is very little grown in the district. Messrs. Bath also grow a French dessert Plum, *La Délicieuse*, to a small extent. Usually it bears well, but not this year. Prince of Wales bears the best crop this season, while Victoria is fruiting fairly in parts of the orchards. On the whole, neither Apples nor Plums are considered up to average, though we saw none elsewhere in Wisbech equal to those under notice.

Careless is regarded by our conductor as the best Gooseberry, and it is less subject to mildew than any other variety. Other Gooseberries in favour are Lancashire Lad and Lancer. The crops on the three varieties named are fair to good, while

Whinham's Industry is less satisfactory. Messrs. Bath and Co. obviously have faith in a continued demand for Gooseberry bushes, in spite of the discouragement caused by American mildew, as they have a block of 300,000 yearling bushes and 100,000 cuttings.

Bath's Perfection, Balmforth's Seedling, and Hornet are the Raspberries most in favour, and they are promising good crops. The Strawberries most grown are Royal Sovereign, Sir Joseph Paxton, The Laxton, and, as a late variety, Cropper. Strawberries had been injured by drought as well as by frost, and it was astonishing to see them so promising after a good rain as they were at the time of our visit.

OTHER ORCHARDS IN WISBECH.

Mr. Cockett has the largest area of top fruit in the district, his orchards covering 400 acres. The Apples which he grows most extensively are Lord Grosvenor, Early Victoria, Stirling Castle, Grenadier, Keswick Codlin, and Bramley's Seedling. The first five are bearing well this year, while Bramley is fruiting partially. Some very large old trees of this variety in an old orchard show a good crop; but the foreman said this was not general, as it is not a Bramley year. Here and in several other orchards we saw immense trees of a local variety named Green Harvey, a tremendous bearer in alternate years. It was stated that an average of 5 cwt. of Apples of this variety per tree had been grown, while an individual tree here and there had produced $\frac{3}{4}$ ton to 1 ton. One ton would be equivalent to 56 bushels of 40lb., and this seems an incredible crop, even for a tree of enormous size.

The principal Plums grown are Victoria, Prince of Wales, Belle de Louvain, and Czar. The Plums in the orchards seen are bearing better than in most others in the district. Another local Apple seen in two or three orchards is Margaret Henrietta, a small red dessert variety of poor quality, but in good demand in Northern markets. This variety is a tremendous cropper. In one case we saw some trees of it so crowded together that sun and air could get freely only to the tops, and these, spread out like an immense umbrella in a compact mass of branches, were densely covered with fruit.

Lord Grosvenor is an Apple greatly in favour at Wisbech, as it is a great and almost regular cropper. It cankers badly in some of the orchards, if not in all; but the growers put up with that fault for the sake of this Apple's productiveness.

Black Currants are so very little grown in Wisbech that we neither saw nor heard of more than one piece of considerable area, and this was almost devoid of fruit. The two reasons given to us for not growing Black Currants at Wisbech and in another part of Cambridgeshire were that they become badly infested with "big bud," and that the crop is frequently cut off by spring frosts.

Mr. Miller took us last of all to see his own fruit garden in Wisbech. Most of his fruit land is at a distance, some of it being in Suffolk. His home garden is well cultivated, and beautifully clean. Here we saw the only piece of outdoor Tomatos noticed in the course of our tour; but Mr. Miller grows them chiefly under glass, and these are highly promising crops. A good block of young Pears and cordon Apples attracted our attention. James Grieve and Newton Wonder are fruiting well, whilst Lane's Prince Albert, as nearly everywhere, is almost bare. Gooseberries and bulbs are grown among some of the trees. A variety of Gooseberry known as Roaring Lion bears a great crop. Some old trees of the Green Harvey Apple and Hessele and Cluster Pear are of enormous size. In fruiting seasons they bear very great crops.

SOMERSHAM.

A few orchards at Somersham were looked at cursorily in passing on our journey towards Wil-

lingham. Most of the trees of the Plum, Damson, and Cherry that we saw were almost bare of fruit, and Apples were thin. Frost, it appears, did a great amount of damage to fruit of all kinds in this parish.

WILLINGHAM.

One of the best-managed orchards in Willingham is that carried on by Mr. J. F. Thoday, and is about 50 acres in extent. Here we saw some of the best Plum crops noticed in the course of our tour in Cambridgeshire. The Cambridge Greengage is fruiting well, and this is the case generally, Mr. Thoday informed us. He has also good crops of Czar and Bush Plums, and a fair one of Early Rivers, The Bush, and Cox's Emperor, while Victoria is nearly bare, and the fruiting of Monarch is partial. Hessele, Pitmaston Duchess, and Joe Wilson Pears, the last being a local variety, bear fair to good crops.

Mr. Thoday's principal Apples are Bramley's Seedling, Lord Suffield, and Beauty of Bath, and these are fruiting well for the season. Lane's Prince Albert is nearly fruitless. Willingham is in the midst of a great Plum district, and it is estimated locally that the crop in the district is only half an average one, Mr. Thoday being exceptionally fortunate. He has a large expanse of glasshouses, which we had no time to visit.

In the adjoining parish of Cottenham there is a large acreage of fruit. Here we had to be contented with inspection from the roadside, as an appointment further on prevented a protracted enquiry in the parish. Both Apples and Plums, we were informed, are much under average.

HISTON.

At Histon, where Messrs. Chivers have a great jam factory, the firm kindly sent their fruit manager to show us one of the fruit farms which they hold. Their scattered orchards extend over some thousands of acres.

For a wonder this season Lane's Prince Albert is among the Apples bearing well in parts of the orchard visited, some of the other varieties showing a good set of fruit being Worcester Pearmain, Queen, Histon Favourite, Bismarck, and Bramley's Seedling in some blocks. Stirling Castle and Keswick Codling are not cropping well, whilst Beauty of Bath shows about half an average crop.

Frost did some damage to Plums, Strawberries, and Raspberries at Histon, but little or none to Apples. The Strawberries seen, however, were promising after a recent fall of rain, and some good crops of Prince of Wales, Greengage, Pershore, and Early Rivers Pears were seen. The prospective yields of Plums and Apples on the whole are put below average. Aphid has done a great deal of damage to Plums. Damsons in this particular orchard are fruiting well.

Black Currants are only half a crop. They started well, but "ran off" in consequence, presumably, of drought. Cherries are good.

Spraying in these orchards is done by means of portable main pipes and hose, the work being driven by an engine capable of serving twenty-four sprayers. In another place Messrs. Chivers have underground mains.

In another orchard in or near Histon, which we entered on seeing the manager as we were passing, we found Black Currants very thin on the bushes, as they had "run off." Here Worcester Pearmain was seen to be cropping well, while Lane's Prince Albert was fruiting only in places. No Damsons were seen on the trees, and Plums generally were said to be only half an average crop.

Although this report begins with Cambridgeshire, on account of the great importance of that county in relation to fruit-growing, my tour began in Suffolk, and was continued through part of Norfolk. A description of what was seen in the two eastern counties must be reserved for a second article. *A Southern Grower.*

ORCHID NOTES AND CLEANINGS.

HYBRID ORCHID RECORDS.

At a recent meeting of the R.H.S. Orchid Committee, Mr. J. Gurney Fowler, chairman of the Committee, laid before the members a scheme for the classification of hybrid Orchids under the species entering into their composition, and with reference to those hybrids or cross-bred varieties in which three or more species were used. Dealing with the *Laelia*, *Cattleya* and *Odontoglossum* hybrids, of that character which have obtained awards at the Royal Horticultural Society, he has prepared an analysis running into over 700 lines, the first item in each line being an original species, the second the species forming a primary cross, and followed by the third and successively by all other species concerned in each cross, the recognised name of the plant being given after the names of the species concerned in its production.

A study of Mr. Gurney Fowler's little book is very interesting. For example, with *Laelia purpurata* as an original it appears sixty-three times consecutively, with *C. Dowiana* in the second line twenty-four times, and with the introduction of other species the sixty-four distinct crosses are obtained, in many cases the third agent being a hybrid.

THE ROSARY.

VIEWS ON CLASSIFICATION.

In the *Rose Annual* for 1914, a number of rosarians contribute notes on the question of Rose classification. The following are summaries of these views expressed by those who favour a radical change in the existing system on the subject which is discussed on p. 438.

Mr. A. Dickson's view is that hybridists have broken down all existing lines of demarcation between what were once well-defined groups, and he proposes to divide the Roses of our gardens into four sections, viz.: (1) Bedding Roses; (2) Exhibition Roses; (3) Shrub or Bush habited Roses; and (4) Climbing Roses; each of which may be again sub-divided into groups. The first section, Bedding Roses, is divided into three groups according to estimates of their vigour of growth. In group A we find Hugh Dickson, Grüss an Teplitz, Frau Karl Druschki, La Tosca, and Dorothy Page Roberts; in group B Roses of such different habit as Caroline Testout and Lady Hillingdon; while as typical of group C are given 3 H.T.'s, Madame Ravary, Richmond and Le Progrès, a China Comtesse du Cayla and 2 Polyantha Pompons, Orleans and Jessie.

When we come to the 2nd section, "Exhibition Roses," we find some of the best for this purpose have already been used in the other sections. This, therefore, is to be confined to such Roses as are useless for any purpose other than exhibition. It would indeed prove an index expurgatorius. Section 4 for Climbing Roses is sub-divided into groups: (a) Wall Roses, (b) Early-flowering, and (c) Late-flowering. These groups bring together some odd combinations; thus we find Climbing Mrs. Grant associated with Noisettes, such as W. A. Richardson in group A (Wall Roses). Early-flowering Climbers are put into group B, which includes both multifloras and some Wichuraianas; while group C, late-flowering, has some Wichuraianas, Paul's Single White and Climbing Lady Ashtown. Surely Climbing Mrs. W. J. Grant and Climbing Lady Ashtown are far more like one another in habit and form of flower than either of them is to the others of the groups in which they are here respectively placed. Now admitting Mr. Dickson's premises that the borderland between two neighbouring groups cannot be readily defined, yet the typical plants are well known, and the plants on or near the border line could at least be arbi-

trarily defined, and the direction in which they vary from the type could be indicated if necessary. If this were done, surely it would tell us more of Jessie to know that it is a poly. pom. than that it is a member of a group comprising Comtesse du Cayla and Richmond: similarly, to know that Climbing Lady Ashtown is a climbing H.T. would give more information about it than to say that it is a member of a class which includes Hiawatha and Paul's Single White.

Mr. Pemberton's scheme does not differ in essentials from that of Mr. A. Dickson. In effect, he substitutes for Mr. Dickson's section for bush habited Roses a section of "Roses for Decoration," and he adds another section for pot Roses. He does not work out his scheme so well as does Mr. Dickson, in that he gives us no examples. His scheme is, of course, open to the same objections that meet us in Mr. Dickson's, namely, that the same variety might in many cases find a place with equal propriety in two or more sections, and the line of demarcation between them is consequently even less well defined than under the present arrangement. Mr. Pemberton would be willing apparently to retain the names H.T., Tea, etc., at present used, though he seems to think their practical value would be gone.

Mr. G. M. Taylor's article is in some sense a more serious contribution to the discussion, and it is clear that he realises something of the great difficulty involved in a new departure from the established system. He proposes to arrange all cultivated Roses into three primary divisions:—(1) perpetual-flowering, (2) summer-flowering, (3) autumn-flowering Roses, each division being again sub-divided as hereafter mentioned. Dealing first with the primary divisions, we have a scheme which at least depends on definite characteristics of the plants, and which, if practicable, might afford useful and definite information as to the plants in the respective divisions, and might be free from the vice of overlapping. The distinction between perpetual-flowering and autumn-flowering varieties is in some sense original. The question is whether it is capable of being sufficiently sharply defined to permit of its general application for differentiation. Even between the summer and autumn flowering sections the dividing line would often be far from clear. If we take the Wichuraiana group, for example, this would be split up between divisions 2 and 3. Dorothy Perkins, François Foucard and Coquina would undoubtedly have to go into division 3, while perhaps the bulk of the group would be found in division 2. Precisely how much sporadic flowering in autumn would avail to shift a Rose into the third division would certainly be difficult to determine, for the same Rose will often differ in this respect in different gardens, and under different treatment. No doubt the Teas and H.T.'s would nearly all be found in 1, while the H.P.'s would go into 3; but what is to happen to Roses like Hugh Dickson and Frau Karl Druschki, which, though they have only two definite growths, yet give us flowers—the first at intervals, and the latter nearly continuously through the season?

But each of these primary divisions is to be further split up, and the sub-divisions suggested are: (A) Garden or Decorative Roses; (B) Exhibition Roses; (C) Semi-double; (D) Single. Here the vice of overlapping is at once apparent, for garden and decorative Roses (section A) will be found in all the sub-divisions, while exhibition Roses, class B, will be found also in class A, and to a less extent in section C.

Dr. A. H. Williams's proposal is no doubt the most elaborate. He has three primary divisions, according to vigour of growth:—(1) Climbers; (2) Bush Pillars; (3) Dwarfs. These again are to be sub-divided into four secondary divisions, according to the type of flower, into (1) Exhibition Roses; (2) well-formed flowers too small for exhibition; (3) loose or irregular blooms; and (4) singles. And each of these twelve secondary groups is to be again parti-

tioned according to their inflorescence into (1) blooms more or less solitary; (2) fair-sized truss; (3) large cluster. The result of this arrangement, if I understand it aright, would be to divide our garden Roses into 36 groups, for which, if it were adopted, appropriate names would have to be found in due course, for no one could be expected to remember how to associate definite characteristics with a mere number. This scheme, though it appears complicated, is certainly legitimate, for it predicates for the members of each of the ultimate groups the possession of definite characters which, however difficult they might be to work out, might be capable of being ultimately ascertained.

Perhaps the next step for testing the value of the proposed new schemes as against the

little-known plant, and, while in some gardens it thrives as easily and multiplies as rapidly as the Daffodil, in others it fails to flower, and gradually dies. Its glorious umbels of scarlet Amaryllis-like flowers are, however, so distinct in colour that there are few gardens in which it is not worth trying. Near the East Coast it is perfectly hardy, and it has been known to withstand over 20° of frost in spring, which is the most trying time, as the bulbs push early into growth. To flower well it should be given a well-drained position under a south wall, where the bulbs can be thoroughly ripened each summer, and where a mulching of leaves to protect it from keen winds in spring is not unsightly. A sunny, well-drained slope in the rock-garden offers an ideal site for it. It then pushes

FIG. 199.—HIPPEASTRUM PRATENSE: COLOUR OF FLOWERS BRIGHT SCARLET.

existing classification should be the working out of the 600 Roses of the N.R.S. catalogue according to the schemes, say, of Mr. Taylor and Dr. Williams. The experiment would be interesting, and even if it resulted in the rejection of these schemes, might lead to valuable suggestions for the improvement of our present classification. *White Rose.*

HIPPEASTRUM PRATENSE.

Hippeastrum pratense (or, as it is better known in gardens, *Ilabranthus pratensis*) was introduced from Chile about 1840, and a flowering plant was figured in the *Botanical Register* for June, 1842. Yet somehow or other it remains a

up flower-stems in late May or early June from 1 to 2 feet in height, each of which carries from three to six flowers in an umbel.

Baker, in his *Amaryllidaceae*, includes it in the sub-genus *Rhodophiala*, a group characterised by linear leaves and open funnel-shaped perianth, with short tube and capitate stigma. In this classification the sub-genus *Ilabranthus* is separated by its trifold stigma. The illustration in fig. 199 was taken from the group exhibited by Messrs. Wallace and Co. at the fortnightly meeting of the R.H.S. on June 3.

NOTES FROM WISLEY.

PLANTS IN FLOWER.

The following plants are flowering well in the moraine:—*Dianthus frigidus*, *D. alpinus*, *Asperula hirta*, *Wahlenbergia saxicola*, *W. croatica*, *Androsace obtusifolia*, *A. glacialis*, *Stachys corsica*, *Viola heterophylla*, *Ionopsisidium acule*, *Silene Hookeri* and *Saponaria caespitosa*. On other parts of the rocky *Saxifraga Cotyledon pyramidalis*, *Onosma taurica*, *Mecanopsis integrifolia*, and the blue *Mecanopsis racemosa* are flowering freely, whilst two particularly fine patches of *Ramondia pyrenaica* facing north make a striking feature. By the side of one of the larger pools *Primula Bulleyana* and *P. sikkimensis* are in flower, and the latter is especially charming in such a position. In the shade of the wood, *Lilium rubellum*, a Japanese species with delicate old-rose coloured flowers, is very fine. This most charming woodland Lily flourishes well at Wisley, where it grows in a rather damp spot and has been left undisturbed for several years. *Xerophyllum asphodeloides* is flowering in the wild garden. It is a native of North America and bears a compact spike of white blossoms on a stem about 2 feet high arising from a tuft of grassy foliage. In moist positions near the ponds *Iris versicolor*, *I. ochroleuca* and *I. Pseudo-acorus* are in full flower, while the Japanese *Iris* (*I. Kaempferi*) is just commencing to open.

Many flowering trees and shrubs are in bloom, notably *Olearia stellulata*, which needs a rather sheltered place; *Robinia hispida*, *Laburnum alpinum*, *Lonicera involucrata*, with reddish flowers and bracts; *Potentilla Veitchii*, a Chinese shrub, producing white flowers from May till autumn; *Cotoneaster humifusa*, which is prostrate in habit and bears white flowers; *Kalmia latifolia*, *K. angustifolia*, *Stephanandra flexuosa*, *Rubus odoratus*, *R. nutkanus* and *Chionanthus virginica* (Fringe Tree). *Polygonum baldschuanicum* and *Hydrangea scandens* are two excellent climbers now in flower. *Nymphaea stellata* Berlin Variety is blooming very freely in the heated Lily tank, which has been recently constructed near the glasshouses. To grow this Water Lily in the open a temperature of from 70° to 75° has to be maintained in the water at the commencement of growth in the spring, but in hot weather no artificial heat is necessary. Although the plants were only put in during the third week of May the surface of the water is already nearly covered with foliage and a large number of the beautiful, blue flowers are open. The tank measures 20 feet long by 12 feet broad, and the depth of the water is about 2½ feet. *W. D. Cartwright.*

HARDY BIENNIALS.

STRICTLY speaking, a hardy biennial is a plant which is raised from seeds one year and flowers the next, producing its seeds and perishing after it has fulfilled its mission of perpetuating the race. In actual practice, however, it is found in our climate that a number of annual and perennial plants give the best results, or are more convenient for certain purposes, if they are treated as biennials. Some annuals, for example, flower earlier or more satisfactorily if they are sown the previous year, while there are many hardy perennial plants which are at their best the first season after sowing. These, therefore, are cultivated as biennials, and it is found profitable to treat them in this manner, especially as some exhaust themselves by free-flowering, and are liable to be lost during the succeeding winter.

In the cultivation of biennials one of the most common errors is that of sowing too late. The seeds are left unsown until summer is well advanced, with the result that the plants they produce have not time to attain their full development before winter sets in, so that they either fail to flower or are small and ineffective at the time when they ought to be in perfection. This is why early sowing is desirable with hardy biennials, and plants raised in good time will be found much more profitable in every way than those which have been raised late.

Another common mistake is that of leaving the seedlings too long in the seed-bed without thinning or pricking out, the effect being that the plants are poor and stunted, and never attain their proper vigour and beauty.

May, June, and July are the best months in which to sow the seeds of hardy biennials in the open, but in the colder parts of the three kingdoms it is sometimes found desirable to sow them in pots, pans, or boxes under glass at an earlier period. It must be kept in mind that some biennials when too large suffer considerably more in winter than those of medium size. This is not usually the case, however, and every effort should be made to have good plants for planting out where they are to bloom either in autumn or in spring. Some of the hardiest may, with advantage, be sown in the open in April.

The time to plant out is given where necessary under the names of the respective plants, but, wherever possible, those which flower early should be planted in autumn, and those which flower later can either be put out then or in spring. Sometimes this is not possible, owing to the ground being otherwise occupied, and in the latter case great care must be taken in transplanting.

While details are supplied regarding the sowing and after-treatment of the leading biennials, it may be said that the others, where not otherwise mentioned, may be raised by sowing the seeds in shallow drills in sandy soil in the open garden, covering them with fine soil to about twice their thickness, and watering when required in dry weather. They may also be sown in boxes, pans, or pots under glass, or in drills in frames. When the seedlings have made two of their true leaves they should be thinned, or pricked out, about 2 inches apart, so as to allow free growth before planting out.

ALTHAEA ROSEA OR HOLLYHOCK.

The Hollyhock has for a long time been under a cloud on account of the losses and disfigurement caused by the ravages of disease, but this has lately been less virulent than at one time, and there are signs that the plant will regain at least a share of its former popularity. It should be remembered that seedlings are less liable to the disease than plants raised from cuttings or eyes, and that biennial treatment gives the best results.

The seeds may either be sown in autumn under glass, as soon as they are ripe, or in the open air or in a frame in July. The latter is the time generally adopted, and it is recommended for those who have little glass to spare, or who have to purchase their seeds. If under glass the seeds may be sown in boxes or pots of light sandy soil, and covered to a depth of about a quarter of an inch with similar soil, or they may be sown in a bed made up in a frame. In the latter case they should be sown in drills. Seeds sown in the open are put in shallow drills about 6 inches apart, and covered with about a quarter of an inch of fine soil. When the seedlings have made a pair of their second, or rough, leaves, they ought to be pricked out about 6 inches apart, those under glass in other boxes, and those in the open in beds, about 6 inches apart either way. The former may be transplanted into frames afterwards.

The Hollyhock likes a rich, well-manured soil, and should be kept growing freely from the

time of planting out in May until the flowering period. In addition to the double Hollyhocks, there are attractive single varieties, and some of these, if sown early in heat and treated like half-hardy annuals, bloom the same autumn.

ADLUMIA CIRRHOSA.

In this plant we have a pleasing biennial climbing plant, useful for trellises or climbing over shrubs and bushes. It is about 5 feet high, is quite hardy, and flowers in summer if sown in the open, preferably where it is to bloom. The sowing should be made in June or July, and the plants encouraged to make growth by the use of good soil. This plant has graceful foliage and flesh-coloured flowers.

ASTERS.

A few of the Michaelmas Daisy class of Asters have only a biennial duration, and the best of these is probably *Aster Bigelovii*. This grows to a height of about 2 feet, and has good flowers of a fine violet blue. It is hardy, and may be sown in the open from May to July for flowering the next summer.

CARDUUS AND CHAMAEPUCE.

In these genera we have several handsome biennials excellent for effect in the summer garden. They are good "Thistles," and can be easily raised from seeds sown in the open in May, June, or July for the following year's display. They are best transplanted young, and can be cultivated in any soil. *Carduus* (*Cnicus*) *benefidus* is the Blessed Thistle, a handsome plant, about 6 feet high; *C. Kernerii* has rose-purple flowers, 3 feet high; *Chamaepeuce Casabonae* is handsome with its spiny leaves and light purple heads; and the effective *C. diacantha* has lovely foliage, very spiny, and prettily marked with white.

CHEIRANTHUS CHEIRI.

With the exception of some annual Wallflowers which have come into cultivation within the past few years, the Wallflower (*Cheiranthus Cheiri*) is at its best when cultivated as a biennial, the plants being then much more floriferous and more compact than when treated as perennials. There is, also, a vast difference between Wallflowers properly cultivated and those which are either sown too late or neglected in their early stages. In open seasons the seeds may be sown in the open in March or April, although May and June are the times generally adopted. The seeds are best sown in shallow drills of sandy soil and covered with about a quarter of an inch of the same compost. Thin sowing is desirable, and when the plants have made a pair of their true leaves they are pricked out about 2 inches apart in light soil. When rooted, if bushy plants are desired, they can have the points pinched out, and thus encouraged to make side shoots. When these have grown the plants may again be transplanted about a foot apart into good soil, which has been well firmed, and a second pinching of the shoots may take place if the plants have been raised early, but it should not be done after the beginning of August. As early in autumn as the ground is available the plants should be set where they are to bloom. Late and thick sowing, and late transplanting and planting, are causes of failure.

The German Double varieties may be treated in the same way, but it is undesirable to pinch these out more than once. *Cheiranthus Allionii* is a handsome Wallflower-like plant, which is practically a biennial. It grows about a foot high and bears good heads of orange-yellow flowers. It may be treated in the same way as the Wallflowers, and is excellent for the border or the rock-garden. Closely allied to it is *Erysimum helveticum*, a useful border plant, growing a foot high and bearing orange-yellow flowers. *S. Arnott.*

(To be continued.)

CALCEOLARIA "JOHN INNES."

The illustration in fig. 200 shows a hybrid Calceolaria raised at Merton by the present writer during 1912 from *C. plantaginea* ♀ × *C. polyrrhiza* ♂.

Only one seedling was produced. It possesses the rhizomatous growth of *C. polyrrhiza*, with leaves of intermediate characters between those of its parents. The flowers are larger than those of either parent, being 1½ inch long and 1 inch across, the shape suggesting the male parent, but the corolla is not inverted, as in that species.

The ground colour is a deep rich yellow, with irregular chocolate spotting on the front, more heavily spotted at the back, and chocolate blotches inside the throat.

The plant flowers freely, and is a vigorous grower, being readily propagated from the rhizomes. It is likely to prove as hardy as its male parent, having stood two winters in the

and preparation of the manure. Provided, however, that proper attention is given to them, Mushrooms may be grown either out-of-doors or inside with excellent results, and there is no doubt that their culture could with advantage be greatly extended.

THE MUSHROOM HOUSE.

No hard and fast rules need be laid down as to the nature of the house. Good results may be obtained in a plainly constructed lean-to shed with thatched roof, or in a cellar. The essential features are darkness and a fairly equable temperature. To obtain the latter during the warmest months of the year, the house, if constructed above ground, should be given a northern aspect. An earthen floor will ensure humidity. For winter culture the installation of hot-water pipes will be a distinct advantage, providing the temperature is well regulated.

The spaces for the beds may be constructed of wood or bricks. The latter are much the more durable, though many growers prefer

but a bottom heat thermometer is more satisfactory. The mercurial bulb is encased in a sharp-pointed brass tube which can be thrust into the bed, and read at any time without removal. The rise in temperature should be noted daily. Spawning should take place when the heat is on the decline, at about 80° to 85° F. The spawn should be of the best quality obtainable, and procured from a reliable source, as it is folly to use cheap or second-class material. The cakes of spawn should be soaked in water if very dry, though this is only necessary during the summer months, or when they have been left exposed to the air for a long time. They should be broken up into pieces about as large as a hen's egg and inserted in the bed some three inches deep in holes from nine inches to a foot apart, and then firmly covered over. About a week afterwards, if the spawn shows signs of running, the bed should be soiled over, a layer of fresh turfy loam two inches deep, and beaten thoroughly firm, being the best for the purpose. If this is at all dry it should be watered; a hard surface will be no deterrent to the crop. The soil should then be covered with a mulching of clean straw, which will prevent undue evaporation of moisture. The date of spawning should be noted.

The interval from the time of spawning until the beds commence to bear varies, but if all goes well young Mushrooms may be expected in about six to eight weeks' time, and as soon as these are noticed the mulching should be removed, as in a warm structure it tends to harbour insect and other pests. Throughout the season of growth the temperature should be kept between 55° and 60° F., according to the conditions out-of-doors, and damping down should be done as often as necessary to ensure a humid atmosphere. This will be governed entirely by the natural surroundings, but the walls and paths should be kept damp, using as little fire heat as possible. To provide additional warmth some newly-gathered droppings should be spread in the pathway and turned once or twice daily.

BEDS IN THE OPEN.

Those who have not the convenience of a Mushroom house, cellar, or any similar suitable place, may with confidence try the formation of a bed out-of-doors, provided it is built in time to be coming into bearing in the early autumn. Mushrooms may be cut in the open, the whole season through, if beds are spawned in succession, though winter-bearing beds need to be covered with a thick layer of straw in severe weather. The site for spring and summer bearing beds should be shaded from the hottest of the sun's rays. It should be slightly above the natural level, so that surface water drains away readily. Beds constructed out-of-doors differ in one respect from those built inside, i.e., they are ridge formed, with a base usually from 5 to 6 feet wide. The material should be firmly trodden and rammed as the work proceeds. The manure requires preparing exactly as for other systems, but excellent crops may be obtained by the use of equal parts of manure and leaves if the latter are not too decayed, and where a liberal supply of leaves is obtainable their combination with horse manure is to be recommended, for the heat generated is much more lasting and even.

COMMERCIAL CULTURE.

Although the foregoing principles are applicable to the cultivation of Mushrooms generally, the methods adopted are in many cases somewhat different when the crop is grown on a commercial scale. Quantities of first-class Mushrooms are grown in old limestone pits, shale mines, quarries, disused railway tunnels, underground cellars, old ice houses, sheds, empty Rhubarb forcing houses, and similar positions. Any place which can be kept dark, and where sufficient manure for new beds can be stored to maintain a temperature of 60° F., is suitable.

FIG. 200.—CALCEOLARIA "JOHN INNES" (*C. PLANTAGINEA* × *C. POLYRRHIZA*).

open garden. It did not prove to be self-fertile, but when crossed back with *C. polyrrhiza* it gave seedlings varying in leaf and flower characters between the original cross and *C. polyrrhiza*.

About thirty of these seedlings have come through the winter in a border out of doors, where they are now coming into flower.

Two more seedlings have been raised this year of the original cross (*plantaginea* × *polyrrhiza*). They are like the first, except that they both lack the spotting on the front of the "pouch." *E. J. Allard.*

MUSHROOM CULTURE.*

MUSHROOMS are sometimes regarded, particularly by small growers, as an uncertain crop. Failures may be due to bad spawn—especially when the crop has been grown indoors, to the unsuitability of the structure, or to the quality

woodwork. If woodwork is chosen, it must be strong, especially if it is decided to have another tier for successional beds. This economises space, but at least three or four feet should be left between the tiers to admit of proper working. Each bed should be two feet six inches deep. Less depth would suffice, but the beds will continue in bearing longer, and be generally more satisfactory, if the depth stated is allowed.

PREPARATION AND SPAWNING OF BEDS IN HOUSES.

The preparation of the manure for inside beds is important. The manure from corn-fed horses is best; it should be freed from the longest litter, but the shortest straw ought not to be too searchingly removed. The newly collected droppings should be spread out in a dry shed not exposed to the sun and drying winds, and turned frequently to allow the rank heat to escape. Afterwards the dung may be thrown into a heap and turned occasionally, and whilst still warm be brought together and rammed firmly to form the bed. The temperature should then be tested. A stick in the hands of an experienced person may be a sufficient guide,

* Board of Agriculture and Fisheries Leaflet No. 276.

Where Mushrooms are to be grown on a fairly big scale a large quantity of manure is necessary. Only the very roughest of the straw is removed, and the manure is heaped and turned over for a few days to prevent violent heating, or "fire-fang," as it is often called. The manure is then lowered or wheeled into the mines or pits, or conveyed to tunnels in waggons by a central line of rails. In many cases a box 3 feet deep, 3 feet 6 inches to 4 feet broad at the base, and with open top and bottom, the top opening being usually 18 inches to 2 feet broad, is used. This box is usually made the length of the beds, which are run off at right angles to a broad central path at least 6 feet wide. Having placed the box in position, the manure is alternately forked into the box and trampled down hard until it protrudes above the top opening. The box is then lifted off and moved along sufficiently far to allow 18 inches between the beds at their base. This process is continued until all the manure which may be ready at the time is disposed of. As soon as the temperature falls to about 85° F., pieces of spawn 2 inches to 3 inches in diameter are inserted in the beds 2 to 2½ inches deep and about 18 inches apart.

Within a few days of spawning the beds are soiled over with 1½ inches of ordinary black garden or other surface soil. This is sometimes applied by placing a box sufficiently large over the bed to allow of the desired coating of soil being packed down all over the bed. By means of a mason's trowel or an ordinary garden spade and a can of water, a very smooth surface is made on the bed. As soon as one batch of beds has been finished, another batch is commenced, and a continuous supply of heat is thus obtained.

In places such as pits, caves or tunnels, the beds are not so liable to dry and are seldom hayed and strawed. As soon as the flush of the crop is over, the beds are watered with tepid water in which sulphate of ammonia has been dissolved, at the rate of half a teaspoonful to three gallons. Rough agricultural salt is used by some growers in a similar manner, in slightly higher proportions, with good effects. As a result of such treatment a second crop is obtained, and the beds continue to bear for a much longer period.

GATHERING THE CROP.

The gathering of the crop is an important feature. The Mushrooms should never be cut with a knife, but given a sharp twist and pulled clean out, the lower portion of the stem being cut off afterwards. The beds must not be allowed to become dry. They should receive periodically a good soaking of tepid water, and beds that have been in bearing some time may be rejuvenated by watering with liquid farm-yard manure diluted with four times its bulk of water. Some beds, if allowed to remain, will continue to bear more or less for a long time, but usually it is best and most convenient to clear out the old manure, which is useful in a variety of ways, and to use new material for another crop.

The Mushrooms are usually sent to market in 1-lb. punnets, and in baskets holding 2 or 3 lbs., or more. They bear transport well, with little packing, and, if proper arrangements for marketing are made, they may be expected to pay well during the winter and spring months.

PALLIDA-CENCIALTII HYBRID IRISES.

THE Award of Merit given at the Chelsea Show to Iris *Goldcrest* calls attention to a small and little-known group of bearded Irises which includes some of the best garden plants in the family. They are characterised by their self-coloured flowers—the standards are of almost the same shade of colour as the falls, and there is

no veining or blotching under the beard—and by their very straight, erect stems, which carry the flowers well above the foliage. The form of the flowers and their papery spathes are also very

FIG. 201.—IRIS "VIOLA": FLOWERS
BLUISH-VIOLET COLOUR.

distinct, and few Irises rival them in the freedom with which they bloom and their habit of holding a large number of flowers expanded at one time. The illustration of *Goldcrest* in fig. 164, p. 370, shows the shape of this variety, and in fig. 201 is illustrated the habit of *I. Viola*. It will be seen that the stem carries six flowers, of which four are expanded together, at well-proportioned distances. *Viola* is the best of a batch of seedlings raised by Mr. Caparne. The uniform colour of the whole flower is shade 4 of light bluish-violet (202 of the *Rép. de Couleurs*). The beard is small and almost white. *Goldcrest* is almost exactly the same shade of blue, but has a well-marked yellow beard. *Celia* is another form with pale mauve flowers, in colour close to *Albert Victor*. *Penge* is much deeper and has the same rich violet-blue as *I. pallida brionensis*. They all grow 3 or 3½ feet high and have the advantage of lengthening the flowering season of the Iris by flowering earlier than the typical *Pallidas*. R. W. Wallace.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

"STOLEN FROM THE CHELSEA SHOW" (see p. 422).—In a lesser degree we suffered loss at the hands of thieves at the recent Chelsea Show, a number of plants in pots being completely stripped during the night succeeding the closing day. Though our loss was not a serious one, we hope that, apart from any steps the Royal Horticultural Society may decide to take another year, the publicity which you have given the facts may deter the thieves from attempting a renewal of their practices. The instance Mr. Paul cites is particularly unfortunate and regrettable. We join in expressing sympathy with our French neighbours. *Dickson and Robinson.*

APPLYING WATER TO GARDEN PLANTS AND LAWNS.—Readers of gardening journals and of the occasional articles on horticultural subjects in the general Press will have remarked the trend of the writers towards adding to the labours of the gardener in a variety of ways and without any compensating advantages. Some of the writers would have us believe that the greater portion of the country partakes of the nature of the Bagshot sand, being as porous and hungry as the heatland of Surrey and parts of Hampshire, in which water is extremely scarce. But much of the soil of these islands consists of heavy loams, clay and other water-bearing strata, and the rainfall is greater than that of almost every other European country. In the generality of years there is no lack, excepting on soils of a sandy nature. The writer of this note has a lengthy experience in the cultivation of gardens of large size in several parts of England and on varied soils, and is therefore competent to form an opinion on the matter of affording water to plants, the time to apply it, and the duration of its application, whether mulches for the preservation of moisture in the soil are desirable or otherwise, and whether these should be of a manurial nature or not. It may be assumed that when plants are removed from the seed-bed, as in the case of the Brassicas set out in June, if the weather be not rainy, water will be required till they are established, but seldom afterwards. Celery requires much water till it is fit for its first earthing up, but not later, unless there is a cessation of growth. Strawberries planted in the month of August may require water till they have made roots in the soil, if the weather is dry; also beds of Radishes, Lettuces, Violets planted in the spring months with rooted runners should have water applied failing rainy weather, and be often syringed in order to destroy red spider, which is injurious to the leaves. Culinary Peas and Sweet Peas soon go out of bearing and the latter cease to produce flowers if not well supplied with water and mulch at the root, and the same applies to Runner Beans, but is less applicable in the

case of French or Kidney varieties. Fruit trees planted against warm walls, when carrying much fruit, should be afforded two or three copious applications during the course of the summer, slightly loosening the crust with a digging fork to let the water pass to the roots; and if the soil be light and porous, a mulch of spent hot-bed manure after the first application will keep it moist for a few weeks. The same treatment may be adopted with Pear trees on dwarfing stocks and with Apples on Paradise stocks which may be carrying heavy crops of fruit; not otherwise, unless the soil is shallow or very porous. In some heavy soils a hoeing with the draw-hoe at intervals of three to four weeks, so as to keep a crumbly layer at the surface, will be found more advantageous than a mulch of spent manure, preventing undue drying of the soil and favouring the admission of the sun heat to the roots of the trees, etc., so beneficial to most things in heavy land. In regard to the depth the hoe should go, two to three inches is quite enough. With regard to ordinary vegetables, it is sufficient if the hoeing is quite superficial, assuming that in a well cultivated garden no deep-rooting weeds are permitted to exist. Where the soil is light and sandy a difficulty is sure to be experienced in hot weather in keeping lawns and, especially, slopes in good condition, applications becoming necessary almost daily. These are better given in the evening, although on days that are cloudy water may be applied at any time with good results. Lucky is the gardener who has water supplied in underground pipes, for by its means he can easily keep the grass in good order with the least amount of labour. In light land it is of much assistance in keeping the lawn green in a dry season to cover the soil with a layer of clayey loam two to four inches in thickness previously to sowing grass seeds or laying the turves; or, if that be impracticable from reasons of expense or lack of the right material, then to apply finely-sifted heavy loam as a winter dressing annually for a few years. Such soil dressing should not exceed an inch in thickness, the fresh soil being spread evenly and rolled when in a dry condition some days subsequently. On lawns not required for tennis, etc., if the grass is deficient in clover—*Trifolium perenne* minus—a plant of dwarf-growth should be sown in quite small quantities immediately after this dressing is put on the turf, raking it in with a short-toothed iron rake. Manurial watering is an important operation in most gardens for various plants—viz., for vines applied to inside and outside borders, to vines in pots, Strawberry plants in pots, French beans that are being forced, etc. Manures may be employed in the flower garden at intervals in this form, intermittently with clear water, as may be called for, in the case of such plants as *Musas*, *Colocasias* (such as *Antiquorum*), the larger-growing *Solanums*, *Wigandias*, *Ricinus*, *Amarantus*, *Daturas*, *Ferdinandias*, *Hibiscus Manihot*, *Lavateras*, *Melanthus*, and other plants grown in gardens for their leaf effects. Dahlias, Hollyhocks, Shrubby Phloxes, *Nicotianas*, *Minalobata*, *Digitalis* and early-flowering *Chrysanthemums* are greatly benefited by occasional doses of manure water, whilst growing and previously to their coming into bloom. It is a safe rule to use it in a much-diluted state and often, rather than strong and seldom. *Critic.*

WASPS (see p. 423).—It may interest readers to know that this spring, up to the end of May, 1,769 queen wasps have been caught in these Gardens. For the past six years my employer has paid to the men on the estate 2d. for each queen wasp caught up to the middle of June. But this year the wasps have been so numerous he has paid each man 2d. each for the first 100 and 1d. each for all over 100. Some years the wasps devour very large quantities of fruit; in fact, it has been quite a dread to gather the ripe soft fruits from the trees. It would be interesting to know what other employers do to check the increasing wasp plague. If your correspondent, Mr. C. Nicholson, would like the collection from here to report on it, I would be pleased to send it to him. *H. Ranson, Holmbury Gardens, Dorking.*

GRASS IN THE ROCKERY.—One or two papers, including the *Times*, at the time of re-

porting the exhibits at the late Chelsea Show, rather took exception to the grass representing a piece of upland Alpine "Meadow" in my exhibit, and there was more than a hint conveyed that it is not possible to keep grass within bounds in an ordinary rockery in an English garden. I think, however, it is to be managed by sowing dwarf varieties of grass on a shallow stratum of peaty soil, underneath which is a good solid bed of soft magnesian limestone. It should not be much trouble to weed any coarse grasses out that may have strayed in with the soil or seed. I contend that where our close "swath" is successful it will not be necessary to cut the grass before June or July, and even then so little may be cut off that the flowered stems of *Gentians*, *Primulas*, and *Orchids* are merely "ended" in such a manner as will tend to the welfare of the plants—practically the fruits only being removed. It is a pretty experiment and worthy of trial. I have already succeeded with *Gentiana verna* and *Primula farinosa* a second season in grass—and Mr. Irving at Kew is trying *Gentians* in it. *J. Wood.*

THE SOURCE OF YELLOW ROSES.—The admirable article from the pen of *White Rose* upon "The Source of Yellow Roses" (p. 343) has been productive of a few questions upon the subject from another writer under the *nom de plume* of *Experience*. There is little use, I imagine, endeavouring to trace the ancestry of such Roses as *Marechal Niel* and *Duchesse D'Auerstaedt*, for, so late in the history of these varieties, any pronouncement can only be speculative. It is undoubted that nearly all of the older yellow Roses owe their origin to a promiscuous sowing of seed obtained from seed pods set without any artificial aid from the hybridist, and insect agency is possibly responsible for a large number of the fine old sorts raised many years ago. In the old days accurate records of parentages did not exist, and it would be futile to attempt to supply them now. But our modern hybridists are working upon more scientific lines and upon a more certain basis. The modern Rose breeder has gone to totally different varieties to obtain the present-day yellow Roses, and in several of the fine sorts of recent origin that are now in commerce the ancestry is apparent to any careful student of the evolution of the queen of flowers. *Experience*, in his note, says it is quite evident that if we go to the various yellow species—or alleged species—mentioned by *White Rose* we shall obtain Briar-like nature in our crossings, and can we improve on what *Pernet-Ducher* has done and is doing in this direction? That question is, I think, easily answered. The work at present being done by the illustrious French rosarian has already been done, and done well, by one of our famous British raisers. So long ago as 1844 a writer in one of the responsible horticultural journals of that period stated that he found *Harrisonii* and *Double Yellow* to set seed freely when impregnated with pollen from other Roses. The British raiser to whom I have referred has sent out during recent years many most excellent yellow Roses, and I know that he was using pollen from *Persian Yellow* as far back as 1884. The raiser in question never divulges his parentages, but in the catalogue of his firm for the season of 1912-1913 he takes the grower of Roses a little into his confidence. Writing of the fragrance of Roses, he states that the true Rose perfume is the old damask or Attar of Rose odour; that the "Tea perfume" speaks very decisively for itself; and it is, however, to the *Persian Rose*, with its unique fragrance, that we are indebted for the exquisite perfume so much appreciated in the newer yellow Roses. These words are taken from the catalogue of Roses issued last season from the famous *Newtownards* nurseries. I confess to some considerable interest in the evolution of Roses and endeavour to study the subject very carefully and closely. I felt certain that the noted Irish firm must have been using Briar blood for a long period, and Mr. Alexander Dickson informed me that he first used pollen from *Persian Yellow* thirty years ago. The breeding in of colour and fragrance from the *Persian Rose*

is a triumph of hybridisation, and so carefully and thoroughly has it been done that all the undesirable qualities of the Briar, including its unquestionable tendency to black spot, have been eliminated. The National Rose Society has decreed that a certain race of Roses shall be designated as *Pernetiana*, in honour of an esteemed French raiser, and no one will grudge him the distinction. Nevertheless, the fact remains that honours should also be bestowed nearer home, and the future historian of the evolution of Roses must certainly credit the house of *Newtownards* with a worthy and honourable place in the building up of a race of elegant and refined yellow varieties. *George M. Taylor, Mid-Lothian.*

SEVERING OF IVY STEMS (see p. 422).—In your issue of June 13 Mr. H. G. B. Biddesden writes: "I shall be glad to know if any of your readers could give an instance of the stem of an Ivy, having been completely severed, continuing to live throughout one summer." I am able to state that ten years ago I severed the stem of an Ivy growing on a building 3 feet above the ground, and removed the roots entirely. With the exception of a little drooping for the first few days the Ivy was none the worse for the operation, and is at present growing as well as ever. It has often been examined by others as well as myself, and we are convinced that it has no connection with the ground whatever. *James Wood, Hedsor Park.*

THE LESSER NARCISSUS FLY.—The main points brought out in the recent correspondence concerning the lesser Narcissus fly (*Eumerus strigatus*) have been that many larvae feed in one bulb, that they are to be found feeding in March and April, and that they may be merely scavengers. Reasoning from the habits of allied insects is in this case of little value, for the larvae of the *Syrphidae* or hover flies exhibit most remarkable variations in their feeding habits and in their habitats. Some are predaceous upon aphides; some devour living plants; some feed in the most filthy of decaying matter. (Many will remember *Virgil's* recipe for starting bee-keeping. No doubt his final product consisted of swarms of drone-flies!) The following facts may be of some interest. The larvae from bulbs lifted in April pupated almost at once, and flies hatched out from them in early May. Even larvae submerged in water for 72 hours behaved in this way. The eggs laid by these flies have hatched, and the larvae may now be found feeding, a dozen or more together, in the necks of *Narcissus* bulbs. There seems to be no doubt whatever that they enter at the neck of the bulb. They may be found feeding in bulbs which show no other damage than can be accounted for by the larvae feeding in the bulb, though this is not always the case. One we have before us as we write has the upper half inch of the bulb within the neck reduced to a brown semi-liquid mass in which the larvae are feeding, and this is the only damage the bulb has suffered. Another, on the contrary, is suffering also from basal rot, and the larvae have penetrated further into the middle already. The decay set up is of the same nature as, and very similar to, that following the attack of the Onion maggot upon Onions or Shallots. It is clear that at least two broods of the flies appear within the year; that, at least at times, the larvae attack healthy bulbs; and that it would be wise to examine all bulbs lifted now with care, and to destroy all those containing the larvae. *Fred J. Chittenden.*

—Apparently Mr. Shea still misses the real point of the matter. It is not whether the larvae of the *Eumerus* "burrow into and attack the necks of the *Narcissus* bulbs," which we all know they do, but whether the bulbs so attacked are sound and healthy ones or not, for which there is at present no entirely satisfactory evidence either way. But I agree with Mr. Shea that those who are investigating the matter on behalf of the Board of Agriculture are certainly "not so stupid," and will now give their attention to the point, and, before we are called upon to take any special measures, will produce for us definite proof one way or the other. This has been the whole and sole object of my calling attention to it. *A. J. Bliss.*

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

THUNIA.—The flower-scapes of these Orchids are developing, and if the pots have become filled with roots, feed the latter about twice a week with weak liquid-manure made from cow-dung. As soon as the flowers have expanded, the plants may be removed to a cooler and drier atmosphere, where the flowers will last much longer. These plants are serviceable for house decorations, and if the roots are kept moderately dry the plants should suffer no harm during the time the flowers last in perfection. After the flowers are over, afford the plants every encouragement to complete their growth: they should receive plenty of light.

PHAIUS.—Hybrids of *P. Humblettii*, including *P. Cooksoniae*, *P. Phoebe*, *P. oakwoodiense*, *P. Doris* and *P. Chapmanii* have finished flowering and the new growths are developing roots. Therefore the plants may be repotted. The habit of the plants of this section is much more compact than that of *P. simulans* and its class, and it is not desirable to disturb the roots annually for repotting if the condition of the plants warrants its postponement. Surface moss that has become overgrown should be removed and replaced with fresh moss, whether repotting is practised or not. Small plants soon fill their receptacles with roots, and it is generally necessary to repot them annually. For compost use a mixture of turfy loam, peat and leaves in equal portions, with sufficient sand, charcoal and broken crocks added to render the materials porous. The plants should be shaded carefully until they have become re-established. During the season of active growth, when the pots are filled with roots, the plants require a plentiful supply of water. A temperature of about 70° should be maintained at night during this stage, but in the resting season 65° will suffice.

DENDROBIUM FORMOSUM.—This Orchid has become popular in private gardens during recent years for the purpose of furnishing white flowers in the autumn. The plants are growing freely, and any necessary repotting should be done as soon as the roots are active. The plants require a liberal amount of strong light from the time growth commences until the flowers expand in the autumn, but they must not be exposed so much as to cause scorching. A hot, humid atmosphere should be maintained and the roots liberally supplied with moisture until growth matures, when cooler and practically dry conditions should be afforded.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to EARL BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

FLOWERING SHRUBS.—The shrubs in these gardens have never before in my experience been more damaged by spring frosts. Many of the newly-introduced species especially have been damaged. The minimum temperature was 60° on one night and 24° two nights afterwards. Shrubs that had been pruned after flowering and made new growth were cut back by the frost and have had to be pruned again to sound wood. It is very doubtful if this later growth will ripen sufficiently to flower next season. Magnolias, Buddleias, *Deutzia carminea*, *D. densiflora*, *D. kalmiaeflora*, *D. corymbiflora*, *Stephandra flexuosa* and all the Japanese Acers have suffered severe damage, whilst *Corylopsis spicata* and many others have been cut to the ground level. All these plants have in former winters withstood much more severe frosts; the damage was largely by reason of the tender condition of the young growths.

ROSES.—Aphis has caused us much trouble this season, the Roses requiring attention daily to keep them clear of green fly. There has been

one continual migration of the pest on the wing, and as fast as one infestation has been destroyed by spraying, the hushes have been freshly attacked. Madresfield is in a Hop-growing district, and our persistent attacks of aphis may be due to migrations from the Hop fields.

THE TERRACE GARDEN.—Grass verges must be made neat and trim and lawns kept mown. Should Plantains or other coarse weeds appear in the turf, destroy them with the "Wikeham" weed eradicator. Keep the flower-beds tidy, and see that the plants are properly supported and stopped as required.

SEED-SOWING.—It is time for sowing (in a cold frame, for preference) spring bedding plants, such as *Polyanthus*, *Aubrietias*, *Wallflowers*, *Myosotis*, *Alyssum saxatile compactum* and other biennials. Partially shade the seed-pans until the seeds have germinated in order that the soil may keep moist without resorting to watering; for the same reason maintain a humid atmosphere about the seed-pans of the seedlings. Many herbaceous perennials come true from seed, and now is the best time to sow them. Seedlings are always more vigorous than plants raised from cuttings or by division. The fine Genm Mrs. Bradshaw may be raised from seed sown now. *Campanulas*, *Oenotheras*, *Aquilegias*, *Thalictrums*, *Veronica subsessilis*, *Pentstemons*, *Rudbeckias*, *Sweet Williams*, *Brompton* and winter-flowering *Stocks* are all easily raised from seed.

THE IRIS GARDEN is now the gayest and most pleasing feature in the flower garden. Irises flower over a long season, and the plants seldom fail. *I. Monnieri* and *I. ochroleuca* have been extra fine this treacherous season.

THE BULB GARDEN.—The foliage is now nearly ripe, and the long grass may be mown where bulbs are planted in turf. The sun will ripen the bulbs, which is very important if good flowers are expected next season.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY,
Knowsley Hall, Lancashire.

VALLOTA PURPUREA.—The plants show signs of completing their growth, therefore water should be withheld gradually, allowing the bulbs to rest from now until September. Stand the plants on a staging or ash bottom in a cold frame in full sunshine to ripen the bulbs. It is not necessary to repot *Vallotas* oftener than every third or fourth year. Early in July is a good time to top-dress or repot established bulbs; the compost should consist of equal parts loam, leaf-mould and sand, with a little bone-meal added. Pot firmly and keep the soil almost dry until September. Imported bulbs should be potted in October.

HUMEA ELEGANS.—A few seeds of this sweet-scented plant may be sown now, and another sowing made about the middle of July. Sow the seeds thinly in a pan of finely-sifted soil, barely covering them. Place the seed-pan in a cold frame, and cover it with a piece of glass or paper. As soon as the seedlings can be handled they should be potted carefully and grown on. Strict attention must be paid to watering, for an excessively moist soil must be guarded against. Admit plenty of air on all favourable occasions. Unlike most plants, *Humeas* are not benefited by wetting the foliage.

PANCRATIUM FRAGRANS.—The flowers are almost over and fresh leaves are developing. Examine the plants with a view to top-dressing any that require this attention, using a mixture of three parts loam and one part each of pulverised cow-manure and leaf-mould, adding a little charcoal and sand. If any plants require repotting, the work must be done very carefully, to minimise damage at the roots. Use ample materials for drainage and slightly less cow-manure than advised for the mixture for top-dressing. Plunge the plants in a hotbed until growth is completed, when they may be exposed to full sunlight. Sponge the leaves directly thrips are noticed.

POT ROSES.—To obtain good flowers from Roses in pots early next spring, the plants must receive liberal treatment during the summer

months. Stand them out-of-doors in a light situation, sheltered from cold winds. Remove all flower-buds from plants required for forcing next spring. If repotting is necessary remove a goodly portion of the old soil and use good turfy loam enriched with a little bone-meal. Pot firmly. Cut away all old and useless wood, and then plunge the pots in ashes, affording water very carefully for some time afterwards. Those with soil in a satisfactory condition should be fed with weak soot water and diluted liquid manure. Syringe the plants with clear water occasionally. For combating mildew and green fly, spray the plants with *Quassia* extract.

CANNA.—The earliest plants are in full growth, and should be watered frequently with liquid manure. Plants of later batches may be repotted and grown on in a pit or frame. Water the soil very carefully until the roots are re-established.

MANAGEMENT OF THE HOUSES.—With the exception of stoves and propagating pits, fire heat may be almost entirely dispensed with by judicious ventilation and closing the houses early.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton
Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buck-
inghamshire.

PINEAPPLES.—Attend to old, leggy plants that are not fruiting, and cut them off at the surface of the soil, removing the lower leaves to where the stem begins to soften, shortening the latter if necessary. Pot them firmly into 8 or 10-inch pots, using good turfy loam in moderate-sized lumps. Plants sixteen or eighteen months old having no appearance of fruiting should also be turned out of their pots, some of the old soil removed, and the roots cut back, afterwards re-potting them as mentioned above. This will enable the plants to produce earlier and finer fruit, as the old soil frequently becomes soddened from the presence of worms, one of the greatest pests in Pine cultivation in pots. Place the plants in a close pit having a brisk bottom heat, and water the soil, which will suffice generally for moisture until about a fortnight, when fresh roots will have developed. Plunge the pots in the hot-bed, keep the pit close and moist, lightly syringe the plants overhead daily, and shade them effectually. The temperature at night should be about 70°, with a rise of 10° to 15° in the day-time; examine the bed at intervals to see that the requisite amount of bottom heat is maintained. If the plunging bed is composed of fermenting materials and bottom heat is not supplied by means of hot-water pipes do not use fire-heat unless it is absolutely necessary.

PEACHES AND NECTARINES.—Artificial heat can be discontinued when the early crop is ready to be gathered, and an abundance of fresh air admitted in order that the fruit may be highly coloured and rich in flavour. Examine the fruits daily to ascertain which are ripe, but handle them carefully to avoid bruising. The fruit should be grasped firmly in the palm of the hand, and such as are ripe will part from the tree when pressed lightly against the base. If the fruits are required to hang on the trees until they are fully ripe suspend to the trellis or wires a sheet of soft canvas or netting, or place over the border a layer of dried bracken fern or hay, the value of which will be increased if a sheet of soft canvas or stout tiffany is placed on the top of it. This will ensure that any that may fall will not be bruised. To pack the fruit for transmission it should be wrapped separately in tissue paper with a covering of cotton wool and packed carefully, but firmly, in single layers in the box with a padding of wood wool surrounding each fruit. Pay unremitting attention to the trees in succession houses, as previously directed, and let there be no break in the supply of fruit. Take measures to prevent infestations of insect pests; red spider may be kept in check by affording the borders plenty of moisture. Old trees in the late houses carrying heavy crops of fruit require a regular supply of stimulants. Remove all surplus growth, retain-

ing only those shoots that are absolutely necessary for fruiting the following season.

CUCUMBERS.—Encourage the plants to grow rapidly. If the young fruits grow curled or the foliage looks weak and flabby examine the condition of the bottom heat and also see if the plants are in need of stimulants. It will be found best, as a rule, always to maintain a moderate degree of bottom heat, and to feed the roots liberally with liquid manure. A top-dressing of cow or sheep manure, spread about 1 inch thick, and replaced every fortnight, will attract the roots to the surface. Keep the plants strong and healthy, and afford sufficient water, as the more rapid the growth the larger will be the crop of fruit. Any plants that have not proved productive should be discarded and fresh specimens planted in their places.

THE APIARY.

By CHLORIS.

SANITATION v. DISEASE.—During the past month I have had occasion to examine an apiary, which was infested by the Isle-of-Wight disease a few years ago, when I strongly advocated burning all the hives, as the disease was so bad. Unfortunately, two new double hives were saved; the contents were burned and a fresh start made in them; but the bees died, probably from the same disease. Since then several fresh starts have been made in skeps, and one that came through last winter was examined, and Isle-of-Wight disease was undoubtedly present. The apiarist was induced to make a bonfire to destroy the skeps and bees. On examining the two double hives saved from the last fire, I was amazed to discover their condition. To commence with, the frames and combs were one mass of larvae of the bee-moth in all stages of development, thus being a source from which the pest could be spread to neighbouring hives; the floor-boards were thick with rotting debris and other filth. Luckily, I induced the bee-keeper to destroy the lot, and he has determined to make a fresh start with a swarm he has found. From the foregoing it will be easily seen that much of our present trouble is due to carelessness. The hives should be kept thoroughly clean by having surplus floor boards, so that their cleansing may be thorough, not superficial, as is too often the case. The work is best done by scraping, and afterward thoroughly washing with disinfectant. Then no unused hives with combs should be left in the neighbourhood of the hives for the wax moth to deposit her eggs in, and the ground in the vicinity of the hives should be kept scrupulously clean by hoeing, and occasionally in the winter unslaked lime should be used to purify the soil and kill any germs that may assist in spreading disease. It is a mistake to have hives under hedges and trees where they catch the drip from the trees and are not in a free circulation of air, although a wind-screen is excellent and shade from the mid-day sun a boon.

SHOWING.—As a means of finding a market for honey, exhibitions are excellent. As bee-keepers will now be removing their surplus honey, the best sections should be put aside with this end in view. In some shows shallow frames are admitted. To secure prizes for sections it is necessary that the foundation should be a full sheet of worked comb: it must be drawn out, filled and sealed quickly, so that only those sections filled during a good honey flow are of any use. For this purpose swarms generally do the work best, by producing clean, straight comb with an even capping. Those who have been most successful on the show bench have given great attention to selecting a strain of bees which give the best results in the points named above. Use two bee-way sections, with split top and grooved sides, and if the inside of the wood be coated with a thin covering of hot wax the bees will then probably attach their comb to the wood all round. To perform this operation successfully warm the sections and put on the very hot wax with a brush, taking care that no wax gets into the "V"-shaped joint, or the section will not fold true, as the painting is done while the sections are in the flat. To make the sections square and

quite true it is best to use a block. The girders of the rack are made of flat wood about three-quarters of an inch wide and three-eighths thick. The sections must then be wedged up quite tightly, to leave no space for the bees to fill with propolis to stain the wood and make much extra work to remove. T-girders should be avoided, as the spaces are always filled with propolis. Dividers are needed, and as those of metal are thinnest they are much to be preferred to wooden ones, and those that give the closest fit will conserve the heat best. It is often said that bait sections (i.e., those partly filled) will cause the bees to use sections readily, and this is quite true; but most people place them in the centre, which is wrong, for the bees fill the inside frames without much inducement; so place them on the outside. Then the racks cannot be wrapped up too warmly, leaving no openings through which heat can escape or a draught may arise. It will be seen that a "W. B. C." hive is of great advantage. As soon as the sections are filled they must be removed or they will become travel-stained, and in some cases the bees thicken the cappings, and this results in a deduction of points at the shows. To prevent the bees puncturing the cells, use as little smoke as possible. A Porter bee-escape will reduce the possibilities of this danger. To get good sections of heather-honey the racks must be fitted up with drawn-out comb. Clean all the wood of the sections by scraping, then store in a clean cupboard until the time of the show. Just before the show glaze with glass cut to the exact size and use white paper lace not more than three-quarters of an inch deep. Afterward paste around the four sides strips of white paper exactly flush with the edge.

THE KITCHEN GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

CARDOONS.—The plants are ready for transplanting into trenches where they can be blanched easily, in much the same manner as Celery. Cardoons, however, are a less exacting crop, needing a merely fairly fertile soil; but they must have a larger space for leaf development, or about 2 feet apart. In dry weather, until the roots are re-established, water must be applied. It is not too late in warm districts to sow seeds for a late batch, though too late in the north.

WITLOOF.—This is a kind of Endive—or, rather, an improved form of the allied Chicory, which, like Endive, is blanched during winter and spring. It is now full time to sow seeds in drills made at a foot apart. The crop will grow in very poor soil, but yields more profit in fertile, though not necessarily recently manured, ground. The plants are tap-rooted; therefore it is not usual to practise transplanting, the seedlings being thinned instead to 9 to 12 inches apart. The summer cultivation, in addition, consists in stirring the surface with a hoe and destroying weeds.

JERUSALEM ARTICHOKE.—When this vegetable is planted in heavy soils it is an advantage to stir the ground deeply, at the same time drawing a little soil against the stems. In ground of a loose texture a large quantity of soil should be placed against the stems in order to steady them during times of strong winds, or they may be uprooted. This will be the last attention the crop will need until late in autumn unless the soil be foul, when in a few weeks the surface will require to be Dutch-hoed to destroy seedling weeds.

MUSHROOMS.—If Mushrooms are required in autumn it is time to prepare the materials for the bed. Owing to many horses being at grass at this time, material from the cowhouses has been ere now utilised, but it must be largely of straw, and should be carefully moistened and fermented. Such an unlikely material as Barley straw has also been used and prepared by moistening and fermentation. Neither material, I should say, is very dependable, and it would be better to supplement horse droppings with a larger quantity than usual of the rough manure. Another method of obtaining an autumnal supply is to spawn natural

Mushroom-producing fields. The common Brown Mushroom is the best to employ for this purpose, and no delay should occur in inserting the spawn. Mushrooms were found here last year in May. Puff-balls were plentiful and St. George's Mushrooms abundant slightly earlier.

EARLY POTATOS.—Set apart enough tubers of the best plants for "seed" for another year. If full-grown, the tubers may be sorted at once from among those left for eating and laid out in boxes to "green," and later stored away in the fruit room or other cool place. As the crop is lifted, utilise the ground for a crop of Turnips, Spinach, Lettuces or Radishes. It is not necessary to dig the ground previous to sowing these crops, provided the soil is loosened with a fork when the Potatoes are lifted.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOTE, Eastwell Park, Kent.

DESSERT CHERRIES.—The fruits of early varieties of Sweet Cherry on wall trees are swelling rapidly, and every effort should be made to cleanse the trees of all insect pests before placing nets over the trees to protect the fruit from birds. A selection of the best early varieties includes Bigarreau de Schrecken, Black Heart, Black Tartarian, Early Rivers, Guigne Annonay, and Early Red Bigarreau. The roots should be supplied with plenty of water, and the mulching materials renewed if necessary. The netting, if of a temporary nature, should be made secure, or the birds may enter and destroy the best fruits. It should not hang loose in front of the tree, but forked sticks, about 18 inches long, should be placed at intervals from the face of the wall, and the nets secured to these. But first fasten to the wires all shoots required for extension, and pinch the others as advised previously, for shoots not required must not be allowed to remain. Trees properly treated in this respect in the growing season require very little pruning in the winter. Moreover, neglect of summer pinching involves the cutting out of a large amount of wood subsequently, and this often leads to gumming and the loss of large branches.

BUSH APPLES.—The trees are making rapid growth, and should receive attention both in pinching out some of the superfluous side growths and also in respect of thinning the fruits. The earlier-ripening varieties should be dealt with first. Amongst the best of the early varieties are Beauty of Bath, Mr. Gladstone, Irish Peach, Lady Sudeley and Langley Pippin. The variety named last is a healthy and vigorous grower, crops freely and bears fruits from small to medium size. St. Everard is a new early dessert Apple, ripening in September; it is a cross between Cox's Orange Pippin and Margil, and has received the First-class Certificate of the Royal Horticultural Society. The fruits of small varieties, such as Yellow Ingestre, should not be thinned too freely. Cooking varieties should be much more severely thinned, as many of the Codlin type—for example, Lord Grosvenor and Lord Suffield—set far too many fruits in favourable seasons, and heavy crops ruin the health of the trees.

GENERAL REMARKS.—The dry weather of April and May was unsuited to recently transplanted trees, and such as were not watered and mulched are not looking so healthy as could be wished. The recent showers have benefited them to a great extent, but rains should be supplemented by root-watering, and overhead syringing should be practised in the evenings. If the mulch applied early in the season needs renewing, hoe the surface soil and apply fresh litter. If nothing else can be spared, mowings from the lawn will make a capital substitute for manure. This material should never be wasted, but used as a mulch for all sorts of fruit trees and more especially those recently transplanted. The hoe should be kept constantly busy in the fruit quarters, for thorough cultivation of the soil is of the greatest assistance to all crops. Trees that were grafted this season should be examined, the ties loosened if necessary, and the new growths made secure against damage by wind and storms.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, JUNE 24—

Richmond Fl. Sh. Croydon Hort. Soc. Fl. Sh.

THURSDAY, JUNE 25—

City of London Rose Society's Show at the Cannon Street Hotel, Isle of Wight Rose Soc. Sh. at Ryde (provisional). Roy. Botanic Soc. meet. Sherbourne Floral Fête. Canterbury, Kent Rose Show.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 61.1°.

ACTUAL TEMPERATURES:—

LONDON, *Wednesday*, June 17 (6 p.m.): Max. 74°; Min. 51°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, June 17 (10 a.m.): Bar. 29.6; Temp. 71°. Weather—Bright Sunshine.

PROVINCES, *Wednesday*, June 17: Max. 75°, Bath; Min. 46°, Felixstowe.

SALES FOR THE ENSUING WEEK.

FRIDAY—

Orchids, at 12.45. Japanese Pigmy Trees, at 2. By Protheroe and Morris, 67 and 68, Cheapside, E.C.

The National Rose Society publishes in its Annual for 1914

8 short papers by well-

known rosarians, together with a critical summary of the views expressed in these papers. The summary is from the pen of the late Mr. George Gordon, whose deeply lamented death we record on another page. The papers provide a convenient basis for the discussion of the question of classification of garden Roses. At the same time one may express the hope that fuller inquiry into the subject may be undertaken before a decision is arrived at, particularly if any material departure from the present methods should be contemplated.

At the beginning of last century rosarians, who were perhaps more in touch with the botanists than are many of their descendants, were content to follow the botanical classification, adapting or expanding it where necessary to their requirements. As a rule garden hybrids of botanical species took their name from one of the parents, though sometimes new names were chosen for particular groups. Thus we find Thory in Redouté's volumes forming groups of the garden varieties under the heading *Gallica* and *Centifolia*, while he did not hesitate when necessary to expand his system by forming sub-groups, as, for examples, *Agatha* and *Pontiana* out of *Rosa gallica*.

Again, the hybrids of *R. alpina* became known as Boursault Roses, and those of *R. arvensis* as Ayrshire Roses, while following out the same system of expansion when garden forms arrived which promised to found a new race, appropriate names were provided for the new groups. Thus arose the Alba Roses, the Hybrid Chinas, the Hybrid Perpetuals, the Noisettes, the Chinas, the Hybrid Teas, the multiflora (polyantha), the Wichurianas, and finally the Pernet group, with many others.

As a general proposition no doubt our garden Roses may be regarded as the result of crossing Roses of very numerous species with some form or derivative of *Rosa indica*, long though it may often have taken to find the appropriate com-

ination that should herald the new race. Thus in the case of *R. multiflora*, the early crosses were wanting in hardiness or were unsatisfactory in other ways, until the combination which gave Crimson Rambler and founded the new race of Ramblers, was hit upon after 100 years of more or less unsuccessful experiment.

So long as the combinations were fairly simple this system answered well enough. Now, however, crossing and re-crossing have taken place to such an extent that parentage, thought by some to be an uncertain guide even when known and accurate, is in many cases not known, or at least not published. Not only is there often great difficulty in assigning a new Rose to a particular group, but there exists the danger of the over-subdivision of the present groups. The Garland, for instance, has in different cases been described as a hybrid China or hybrid Musk, and perhaps in despair as hybrid of species. Or again, to take some of the new varieties of bedding Roses, which, it is thought, are likely to be used for purposes similar to those for which we now use the Polyantha Pompons; some of these are believed to contain a considerable share of the Musk Rose in their composition, others of the Wichuriana, and others again may be of uncertain origin, but are thought to have little relationship with *R. multiflora*. Can these properly all be classed as Polyantha Pompons, or, if not, how are they to be grouped? Is there not a danger of over-multiplying our groups and yet failing to afford simple information of their contents? And yet at the same time the Hybrid Tea group has become unwieldy and embraces several types.

At the end of his summary Mr. Gordon propounds two problems as the essential points for consideration. These are:—(1) Shall the existing classification be abolished without first determining that it is absolutely impossible to adapt it to present-day requirements? (2) If found incapable of such modification is either of the proposals now before us sufficient with or without modification to take its place?

We should all probably answer the first question by an emphatic negative, but the practical question suggested by it is rather, Can the present classification be adapted to our requirements? And this may be more difficult to answer. Of the articles under review Mr. Easlea holds that no radical alteration can be permitted without confusion. Mr. Peter Lambert suggests a scheme which is merely a modification of the existing classification. Mr. A. E. Prince accepts the present classification, and Mr. George Paul would keep the existing system with some modifications confined to the autumn-flowering varieties, while Mr. Pemberton does not wish to alter the classification, but desires a new grouping within it. The other writers, Messrs. A. Dickson, G. M. Taylor and Dr. Williams, appeal whole-heartedly for a complete clearance and a fresh start on altogether different lines. From this it might appear that there is a majority in favour

of retaining the existing classification with some modification; but, in fact, this is not so, for if Mr. Pemberton's views be examined more carefully, it will be found that it is only the botanical classification he would retain, which is not really in question, for there can be little doubt that the botanists will do this; in fact, the garden varieties which interest the rosarian would all be somewhat contemptuously dismissed by the botanist as "form. hort.," while if the method of grouping these garden forms which Mr. Pemberton suggests were adopted, its lines would be so different from those now used that it is difficult to see how they could be retained together. We may take it, therefore, that the writers of these articles are equally divided for and against the present system. The suggestions of those who propose an entirely new departure are printed on p. 430. If we examine the views of those who favour the retention of the existing classification, we shall find that Mr. Easlea would be content with a revision of the H.P., H.T. and Tea groups. These he would in effect partition into 7 groups (though he only numbers 5) as follows:—Group 1: H.S. or summer blooming, to include all the H.P.'s and others that bloom sparingly in autumn, e.g., Clio and Conrad F. Meyer. Group 2: H.A. or Hybrid Autumnals, to include such H.P.'s as Mrs. J. Laing, F. K. Druschki, etc., and H.T.'s such as J. B. Clark, Gladys Harkness and others, and Teas such as Mme. Jules Gravereaux. Group 3: H.T.'s or typical Hybrid Teas, e.g., Prince de Bulgarie, Mme. A. Chatenay, Mme. Ravary, and the Teas Molly S. Crawford and Harry Kirk. Group 4: Teas, i.e., true tea-scented varieties. Group 5: H.B. or Hybrid Bedders, such as Ecarlate, Marquise de Salisbury, Edu Meyer, and perhaps Richmond. Group 6: T.M. or Tea Monthlies, which include the present China group, adding thereto Princesse de Sagan. Group 7 would be the Pernet group—A. R. Goodwin, Rayon d'Or, etc. Save that there seems no object in altering the well-known name of the China Roses these suggestions have much to recommend them, and meet the difficulty that has arisen with the Hybrid Teas, which, for a class, have become unwieldy, and embrace too great a variety of growth and flower.

Mr. P. Lambert, Mr. G. Paul and Mr. Prince are all content with the present classification subject to some modifications, which compared with the radical proposals of other writers must be considered moderate. Mr. George Paul's thoughtful article is well worth consideration. With some mutual concession probably his proposals and those of Mr. Easlea might be merged, and would give us all the modification of the existing system that is necessary.

The result seems to be that no new scheme has yet been suggested which would not bring with it greater difficulties than those which we have to face under the present classification, while some more or less conservative modification of the existing system seems quite feasible.

FIG. 202. *GLEMISTIA VENERE*; FLOWERS WHITE WITH YELLOW DISC.
Awarded a Cultural Commendation at the R.H.S. Meeting on Tuesday 14th (1934) p. 439.

Coloured Plate.—The subject of the Coloured Plate to be published with the next issue is Begonia "Eclipse."

MR. ROOSEVELT'S EXPLORATIONS IN BRAZIL.—The brilliant account of his travels which Mr. ROOSEVELT gave before the Royal Geographical Society on Tuesday last, although confined mainly to the geographical features of the country explored by his expedition, contained many observations of interest to the naturalist. The hardships encountered on the expedition were due to the physical features of the country, to the "insect pests," and to lack of sufficient food. To supplement their stores of food, the party had recourse to the tops of Palms, which served as vegetables. They had relied on plentiful supplies of Brazil nuts, but the crop proved a failure. The highlands, in which were discovered the head waters of the unknown river—the River of Doubt—possess a fine climate, and Mr. ROOSEVELT predicts that, owing to their richness in water power, these upland regions of Brazil are destined in the near future to support a large white population given over to industrial enterprises.

SMALL HOLDINGS.—In the course of his speech on the vote of £344,000 for the Board of Agriculture, Mr. RUNCIMAN spoke optimistically of the progress of small holdings. There are now 11,000 small holders, and in addition 1,400 holdings are held under associations. On June 13, 193,000 acres of land had been, or were about to be, acquired. Upwards of £4,000,000 have been invested in holdings, and £65,000 is paid in rent to the local authorities hiring land for the purpose of small holdings. There are 6,000 approved applicants who have yet to be provided with land, and 90,000 acres are required in order to meet their needs. Comparatively few labourers have acquired holdings, and this Mr. RUNCIMAN attributes to the lack of the necessary capital owing to low wages. The President of the Board spoke highly of the work of the Agricultural Organisation Society, and stated that there are 478 agricultural co-operative societies in Great Britain. He believes that the work of these societies has proved of great assistance to the small holder. The Board is attempting to increase the number of paid small holders' advisers.

R.H.S. GARDENS CLUB.—The annual reunion of past and present members of the R.H.S. Gardens at Chiswick and Wisley took place on Saturday, the 13th inst. The event was made the occasion for an outing, and visits were made to Mr. LEOPOLD DE ROTHSCHILD'S gardens at Gunnersbury House, Acton, and Kew Gardens. The party was met at Gunnersbury House by the gardener, Mr. JAMES HUDSON, who pointed out some of the more interesting features of the place, including the fruit and vegetable gardens, the lawns, terraces—with the fine specimen Pelargoniums, Pomegranates, and *Aloysia citriodora*—"Japanese" garden, and flower beds. After the visitors had partaken of refreshments, kindly provided by their host, Mr. ROTHSCHILD himself acted as guide through the fruit houses and the whole of the pleasure grounds, extending as far as Brentford. Mr. HUDSON'S skill as a gardener, and especially with fruit trees in pots, was exemplified on every side. Cherries were remarkably fine, as also were other stone fruits, including Plums, Peaches, and Nectarines, and Mr. ROTHSCHILD gathered ripe fruit for all to taste. The Pinepits, Vineries, Orchid houses, and Lily tanks were visited in turn, and each was an object-lesson in good culture. In the grounds the venerable Cedars were pointed out with pride as being probably the oldest in the country, and Mr. ROTHSCHILD showed his great knowledge of trees and shrubs by his many pertinent references to those in his extensive collection. But the beautiful scenic effects in the grounds are perhaps the greatest attraction at Gunnersbury House, for all who visit it are impressed with the beauty of the landscape. In bidding the

party good-bye Mr. ROTHSCHILD asked to be allowed to defray the expenses of the luncheon which was provided at the Star and Garter Hotel, Kew Bridge. A ramble through Kew Gardens in the afternoon brought a most enjoyable day's outing to a close.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual outing of the members of the National Chrysanthemum Society will take place on Monday, July 20. The party will journey by river from Reading to Wallingford on the steam launch, "The Britannia." The journey from Paddington to Reading will be by the 8.50 a.m. train. Lunch will be taken at the George Hotel, Wallingford, and tea at the George Hotel, Pangbourne, at 5 p.m. The return journey will be made by the 8.10 train from Reading, which arrives at Paddington at 8.58 p.m.

THE COALSTOWN PEAR.—The coming of age of Miss E. C. BROUN-BAIRD, of Coalstown, Haddingtonshire, has revived the story of the Coalstown Pear. According to the legend, one Sir HUGH CLIFFORD, who lived in the thirteenth century, had magical powers. While escorting his daughter to her marriage he plucked a Pear and told his daughter that, so long as it was preserved whole, good fortune would attend her and her descendants. The Pear was carefully preserved in a silver case by the descendants of the lady, but in the seventeenth century one of the descendants, Lady ELIZABETH BROUN, was rash enough to bite the fruit, with the result that the baronetcy went to another branch of the family, the estate remaining in another—that to which Miss BROUN-BAIRD belongs.

AERIDES CRASSIFOLIUM.—In the last issue on p. 410 it was stated that this Orchid was originally introduced by Messrs. STUART LOW AND CO. In the description cited the late Professor REICHENBACH remarked, "For this beauty I have to thank my excellent correspondent, Mr. STUART LOW." The title of the firm at that time was HUGH LOW AND CO.

CELMISIA MUNROI (see fig. 202).—At the R.H.S. meeting on Tuesday last, a good pot of this New Zealand Daisy was shown by Mr. REUTHE, Keston, carrying two well-developed crowns and four flowers. The foliage is particularly firm textured and beautifully silvered below, but the plants exhibited had received cold frame treatment. Miss Willmott, we believe, has wintered the species out-of-doors for the last few years, but coming from an altitude only of 1,500 to 4,500 feet in the northern half of the Middle Island, it is not likely to prove generally hardy. It was introduced by Messrs. Veitch, and was figured in the *Bot. Mag.*, tab. 7,496, in 1896, from material obtained from the greenhouse at Kew. Its close relation and confusion with the variable *C. coriacea*, perhaps the most beautiful species in the genus, is of some interest. Cheeseman (*N.Z. Flora*) says that the plant commonly in cultivation as *C. Munroi* is *C. coriacea*. On the other hand, the Kew plant was thought to be *C. coriacea* until it flowered. The only differences of importance are small distinctions in the corolla and seed. A Cultural Commendation was awarded for the specimen now illustrated.

THE "MASTERS" LECTURES.—The first of the two Masters Memorial Lectures for the present year was given at Vincent Hall on Tuesday, June 16, and the second will be delivered on Tuesday, July 14. The lecturer, Prof. J. B. FARMER, began by saying that in choosing as his title "Some Aspects of Plants in Relation to Their Environment," he had been guided by the recollection of a conversation with the late Dr. MASTERS, on the wealth of material which horticulturists might easily furnish to those whose business it is to try to elucidate the scientific problems that plants present. The lecturer said that he proposed to divide

his subject into two parts, viz., (1) the plant in relation to its physical environment, and (2) the plant in relation to its biological environment. The first of these would form the subject of the first lecture, though, of course, many matters which might be expected to be included would have to be omitted owing to the shortness of the time at his disposal. The main thesis of the lecture consisted in the attempt to show that the behaviour of a plant could be advantageously treated as a problem, or series of problems, susceptible of solution by the aid of chemistry and physics. The advantage of this method—partly, at least—consists in the need it imposes of endeavouring to analyse the factors which are concerned in the production of given structures or in the discharge of special functions. It was admitted that at the present time there is much left to be done—much knowledge to be gained—before this procedure can be worked out in detail. But a great headway has already been made, and everything points to this method of treating the problems as the most fruitful one. For it is only as the result of detailed knowledge of the parts that we can hope to perceive the *modus operandi* of the whole, and be able to step in to control and modify the processes with any assurance of certainty as to results. And this ought to be the aim of those whose business is with plants. It was urged that many of the reactions of the plant to temperature, to nutritive conditions, and to other physical influences, such as light, could be to some extent imitated outside the plant, and although the events which go on in the living organism are of immense complexity, it was shown how some of them, at any rate, could be subjected to useful analysis. The questions of manures, and their effect on growth and fruitfulness, the physiology of grafting, the relation of the plant to the soil, and the absorption of water by roots, were used as illustrations, and were discussed in the light of experiments which had been carried out by the lecturer himself, as well as by other investigators. It was suggested that specific characters were to be regarded as so many marks of individual chemical idiosyncrasy, whereby the raw food-stuff was caused to combine in certain special ways, so as to give rise to the peculiarities in question, but more was promised on this topic for the second lecture. The problem of adaptation was discussed in the light of what had already been said, and the lecturer avowed his disagreement with those who were content to label useful characters as examples of direct adaptations in the ordinary sense of the word. Many characters, both physiological and structural, cannot be regarded as advantageous at all—e.g., the formation of honey dew by Lime trees—nor is it possible to see in the form of most leaves evidence of adaptive modification. Where it exists, closer examination commonly discloses a more elaborate chain of cause and effect, as is shown, for example, in leaf mosaic. To catalogue these as adaptations is to emphasise the least profitable aspect of the problem at the expense of the more truly scientific one which is concerned with real causes and real effects. Naturally, there are many examples which elude analysis at present. That does not, however, alter the general position, nor does it excuse the substitution of a sham for a real explanation. The more we become accustomed to regard our problems from the point of view of science and common sense, the more definitely we shall be able to state them, to analyse them into simpler terms, to solve them, and thus ultimately to gain the sort of control over the plant and its products which the chemist and the physicist have acquired over the materials and forces that lie within their sphere of influence.

GOLDEN WEDDING OF MR. AND MRS. THOMAS BUNYARD.—Many of our readers will remember the pleasantly written and instructive articles on nursery management and propagation contributed to these columns some years ago by Mr. THOMAS BUNYARD, over the nom de

plume "*Experience*," and they will join us in congratulating Mr. and Mrs. BUNYARD on the celebration of their golden wedding this month. Of their fourteen children some are settled abroad, but nine were able to be present to celebrate the event. Four of Mr. BUNYARD'S sons, Messrs. HARRY, PERCY, ARTHUR, and ALFRED BUNYARD, have followed in their father's footsteps in making

of "XL All" fame. He is interested in ornithology, from the horticultural standpoint, and possesses a very fine collection of birds' eggs. Mr. ARTHUR BUNYARD is connected with *Garden Life* and other papers. Mr. THOMAS BUNYARD many years ago was in partnership with his brother, Mr. GEORGE BUNYARD, of the Royal Nurseries, Maidstone, and since those days has filled several appointments with other firms.

example, that illustrated in fig. 203—the stricken tree is torn to pieces as by an explosion, but in the present instance the current graved for itself a narrow channel in the bark of the Poplar, and, as fate so sadly willed it, found its way to earth through the bodies of the individuals standing near the trunk. Of trees, some seem particularly prone to be struck, others are relatively immune. Thus the Oak—as

FIG. 203.—SEQUOIA GIGANTEA STRUCK BY LIGHTNING.

horticulture their profession. Messrs. HARRY and ALFRED have settled in the United States, the former being the general manager of A. T. BODDINGTON AND Co., wholesale seedsmen, of New York, and the latter a florist in Madison Avenue. Mr. PERCY BUNYARD is the London representative of Mr. G. H. RICHARDS,

THE EFFECTS OF LIGHTNING.

THE recent tragic death of several people who had taken refuge from a storm under a Poplar tree at Wandsworth Common has drawn attention once again to the devastating yet capricious effects of lightning. In many cases—as, for

Shakespeare long ago observed—is often struck. The Beech is struck but rarely. It is said that other trees which generally escape are Walnut, Lime, and Birch, but very little is definitely known as to the causes of comparative immunity. One thing is clear, namely, that the danger to individuals taking shelter during a storm is in exact proportion to their nearness to the trunk.

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 16.—The fortnightly meeting and exhibition at Vincent Square on this date was noteworthy for the large number of hardy flower exhibits, two collections of pot fruits, and one of vegetables. Orchids were fewer than usual. The Orchid Committee recommended 1 First Class Certificate and 4 Medals.

The Floral Committee recommended 11 Awards of Merit to novelties, and 31 Medals to collections.

The Fruit and Vegetable Committee recommended one Gold and two other Medals to collections of pot fruits and vegetables.

At the 3 p.m. meeting Professor J. B. FARMER delivered the Eleventh Masters Memorial Lecture on "Certain Aspects of Plants in their Relation to their Environment." (See p. 440.)

Floral Committee.

AWARDS OF MERIT.

Silene alpestris grandiflora flore pleno (see fig. 204).—This is another addition to the very few Alpine plants with double flowers. Its little

orange shades yet attained in the Sweet Pea. The flowers are large, with finely-waved erect standards, and although rather less stout-stemmed than the other varieties with which it was placed, it had every appearance of vigour and of regularity, carrying 3 or 4 flowers on a stem. It appeared to have been grown under glass, and needs trying in the open with the following variety, when the differences now noted might well disappear, and the varieties prove identical. The colour is an intermediate tone of "coral red" (*Rép. des Couleurs*, 76).

These two were shown by Messrs. DOBBIE AND Co.

Sweet Pea "Robert Sydenham."—As exhibited, this was a shade darker in colour than the last. If there was a difference in form it was in the slightly flatter and bolder standards of this variety, and the more horizontal wings, but in this case the flowers had been cut from the open, and petiole, calyx and stem showed a natural redness that the other flowers lacked. Though both varieties are undoubtedly very fine, we think that flowers so closely alike should be in the same conditions before awards are made. Shown by Messrs. THOS. STEVENSON, Addlestone.

Fire Flame, etc.). Shown by Mr. HICKS, Twyford.

Carnation "Bedford Belle."—A perpetual-flowering variety, with flowers of a soft salmon-pink or rosy-pink (*Rép. des Couleurs* 126, tone 1; or 118, tone 2). The flowers are rather roughly formed, but the stems are good, and it is richly fragrant, more so, indeed, than any perpetual-flowering variety we can call to mind, and herein lies its great value. Shown by Messrs. LAXTON Bros., Bedford.

Paony "Golden Harvest."—Immense globular flowers 7 inches in diameter on stout stems characterise this variety. The colour is dominated by the softest lilac-pink of the recurving guard petals, but in the full centre are shades of cream, yellow and pink, making a beautiful harmony. It is not new, and possibly not very distinct, but it is undoubtedly a good thing, responding well to generous cultivation. Shown by Messrs. R. H. BATH, LTD., Wisbech.

Polystichum (Aspidium) munitum undulatum.—This is a very pretty form of this entirely hardy and evergreen species, in which the pinnae for two-thirds of their length are so undulate as to form spiral terminations. The fronds are peculiarly tough, and more lucent than the type. Found wild in British Columbia by Mr. J. Fraser, of Uchulet, British Columbia, and exhibited by Mr. C. T. DRURY on his behalf.

Orchid Committee.

Present: Sir Harry J. Veitch (in the chair), and Messrs. Jas. O'Brien (hon. secretary), Gurney Wilson, R. A. Rolfe, F. Sander, J. Wilson Potter, Stuart Low, F. J. Hanbury, R. G. Thwaites, T. Armstrong, A. McBean, Walter Cobb, J. Charlesworth, C. H. Curtis, W. P. Bound, A. Dye, E. H. Davidson, H. G. Alexander, W. H. White, S. W. Flory, W. Bolton, and Sir Jeremiah Colman, Bart.

Award.

FIRST-CLASS CERTIFICATE.

Odontoglossum King Arthur (parentage unrecorded), from Messrs. J. and A. McBEAN, Cooksbridge. A grand flower of immense size, good shape, and rich colouring. The greater part of the segments were heavily blotched with deep claret-red, the tips and margins being white, but tinged with rose-purple from the dark violet tint at the back of the segments. The lip is broad and well formed, and bearing dark blotches in front of the yellow crest.

CULTURAL COMMENDATION.

To Mr. BALMFORTH, gr. to F. Menteith Ogilvie, Esq., The Shrubby, Oxford, for four very fine specimens of *Cypripedium Lawrenceanum* Hyeannum Bank House variety, a beautiful and free-growing form, which had previously secured a First Class Certificate.

GENERAL EXHIBITS.

E. R. ASHTON, Esq., Broadlands, Tunbridge Wells (gr. Mr. Young), staged an effective group of exceptionally good and well-grown plants for which a Silver Flora Medal was awarded. The group contained many fine specimens of *Miltonia vexillaria*, *Odontoglossums*, *Laelio-Cattleyas*, etc.; specially noteworthy were *Odontioda Ashtonii* (Odm. *Armstrongiae* × *Cochlioda Noezliana*), a good red flower with white lines between the blotching, the margin and front of the lip tinged with rose; *O. St. Fuscien*, and other *Odontiodas*; a very fine *Miltonia* of the *M. vexillaria* Memoria G. D. Owen section; *Odontoglossum Conqueror*, a very fine violet-blotched hybrid, *Odontonia brugensis*, *Miltonioda starwoodii*, some excellent forms of *Laelio-Cattleya Aphrodite*, *L.-C. Ganymede*, and *L.-C. Cowanii*. The centre was of yellow *Laelio-Cattleyas*, and the whole was effectively arranged.

MESSRS. CHARLESWORTH AND Co., Haywards Heath, staged an attractive group of good specimens, their showy *Miltonia Charlesworthii*, and some fine specimens of *M. vexillaria* varieties with 10 to 12 spikes each, being effectively displayed with good *Odontoglossum ardentissimum*, *O. crispum* *Xanthotes*, good *Laelio-Cattleya Martinetti*, *L.-C. Canhamiana alba*, one with two spikes of five flowers each. Among rare species was *Ornithidium aureum* with its singular, yellow flowers. (Silver Banksian Medal.)

His Grace the Duke of MAREBOROUGH, Blenheim Palace, Woodstock (gr. Mr. Hunter), was awarded a Silver Flora Medal for a group com-

FIG. 204.—SILENE ALPESTRIS GRANDIFLORA FL. PL.
(R.H.S. Award of Merit on Tuesday last.)

buttons of full-petalled white flowers are quite pretty, each a little over half-an-inch in diameter, and supported on slender branched stems about 4 inches above the close tufts of linear, green leaves. Shown by Messrs. TUCKER, Oxford, and Mr. G. REUTHE, Keston.

Delphinium "Henri Moissan."—A dense spike 2½ feet long of this fine novelty was shown. The flowers are deep violet-purple (*Rép. des Couleurs*, 192), shaded lightly with a bluish tint, as nearly all the purples are, and with a black eye. The spike shown was just branching out in the lower portion, and would doubtless give a succession of flowers after the main display was over. Shown by Messrs. BLACKMORE AND LANGDON.

Sweet Pea "Royal Purple."—The large, waved, bright purple flowers of this variety, borne finely on stout stems, represent an uncommon colour in Sweet Peas. In the *Répertoire des Couleurs* the shade comes nearest tone 1 of Bishop's Violet (189), or tone 4 of Magenta (182), but its texture gives it a brightness and beauty quite lacking in the paper colours.

Sweet Pea "Dobbie's Orange" (see fig. 205).—This is one of the best of the so-called

Carnation "Scarlet Glow."—A smooth-petalled, rosy-scarlet border variety. The calyx was good, but the stem seemed lacking in wiriness, and we failed to detect any fragrance. Shown by Mr. CHAS. BLICK, Hayes.

Rose "J. F. Barry."—This is a sport from Arthur R. Goodwin, and like that variety, possesses the dwarf bushy habit, perpetual-flowering character, and spiny growths of the *Pernetianas*. The flowers are canary-yellow, the outer petals showing a tendency to turn white. The petals are short, giving the flower a shallow, unshaped form, but the Rose is a very fragrant one, and should prove a first-rate bedding variety. Shown by Mr. G. W. PIPER, Uckfield.

Rose "Princess Mary."—This fragrant, large single, crimson-scarlet Hybrid Tea has already received recognition from the National Rose Society (see p. 303), and is essentially a bedding Rose, and in beds its magnificent glowing colour, size and freedom and fine foliage will make it a very useful variety. But for cutting it has too clumsily-shaped buds, even if the colour were desirable, ever to rival such delicately-formed and shaped flowers as the Irish singles (*Elegance*,

posed principally of White *Cattleya Mossiae* Wageri, both from imported and home-raised plants. With them were *C. M. Reineckiana excelsa*, some very fine forms of *Laelio-Cattleya Canhamiana*, a good *L.-C. Aphrodite*, *Cypripedium bellatulum* and *C. niveum*.

Messrs. STUART LOW AND Co., Bush Hill Park and Jarvisbrook, Sussex, staged a fine group of *Miltonia vexillaria*, *Renanthera lmschootiana*, forms of *Cattleya Mendelii* and *Mossiae*, *Phalaenopsis Rimestadiana*, and *Oncidium Krameri*. Among the *Dendrobiums* were a fine specimen of *D. Dalhousieanum*, with 15 spikes and a beautiful plant of Messrs. Low's early-flowering *Dendrobium formosum giganteum*, with 24 fine, white flowers with yellow centres. (Silver Flora Medal.)

J. GURNEY FOWLER, Esq., Brackenhurst, Pembury, Sussex (gr. Mr. J. Davis), showed *Odontoglossum Aquitania*, a superb flower with the inner parts of the segments blotched with purple.

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), showed fine plants of *Cypripedium Lawrenceanum* Hyeatum, and the handsome *Odontoglossum crispum* Queen Empress, a large typical form tinted with rose.

Messrs. HASSALL AND Co., Southgate, showed a fine form of the white *Cattleya Mossiae* Wageri, good *L.-C. Canhamiana alba*, *L.-C. Aphrodite* and others.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), showed *Odontioda Patricia* Goodson's var. (*Odm. Phoebe* × *Oda. Charlesworthii*), with flowers of a deep claret-red with lighter red lip marked with yellow.

PANTIA RALLI, Esq., Ashted Park, Surrey, showed a very fine form of *Odontoglossum Doris* (*crispum* × *Ossulstonii*), and *Cattleya Mendelii* Knight Templar, a finely-formed and handsome variety.

Mr. ROBERTSON, gr. to Earl Brownlow, Ashridge Park, showed two finely-grown specimens of *Coelogyne Dayana*, with many long drooping racemes of flowers.

Mr. W. SHACKLETON, Highfield Nurseries, Great Horton, Bradford, showed a very distinct form of *Odontioda Brewii* named Highfield Variety with dark violet sepals and petals, and rose-coloured lip with yellow crest.

R. G. THWAITES, Esq., Chessington, Streatham, showed a good white seedling *Cattleya*; and the true *Laelio-Cattleya Canhamiana* Lady Wigan.

The chairman called attention to the rule for entries of plants to go before the committee at Holland House. The entries must be posted not later than the Thursday before the show.

(To be concluded.)

CONFERENCE AT THE WHITE CITY.

JUNE 10.—A conference was held in the Palace of Music at the Anglo-American Exposition at Shepherd's Bush on Wednesday, June 10. Mr. G. Yeld, of York, was in the chair. Papers were read by Mr. R. W. Wallace on "Some Aspects of Modern Gardening," and Mr. S. Arnott on "American Plants which Flower in England." Plants were exhibited illustrating the subjects of the papers.

In his opening remarks the chairman referred to the comparatively few hardy plants in general cultivation in the year 1821, and compared a catalogue of those early times with an up-to-date modern list, showing how, by means of the introduction of species, and also even more by the skill of florists who have raised innumerable varieties, our gardens have become immeasurably richer both in form and in colour.

He said that the cultivation of hardy plants is the most democratic, the most popular, the most easily pursued, and probably the most generously repaying of all forms of gardening.

Before calling upon the readers of the papers he spoke briefly on the improvement which has taken place in hardy plants during the last 100 years.

Gardening has in these days come by its own on both sides of the Atlantic. So far has the passion for gardening gone, so great is the demand for works on gardening, that one-half of the front of the chief bookseller's shop in York has lately been turned into a miniature garden with flowers and dwarf shrubs, while the other half was filled with works on gardening.

By the kindness of Mr. James Backhouse, of the York Nurseries, he had been allowed to examine the list of "Ornamental Annual, Bien-

nal, and Perennial Plants" sold by Thomas and James Backhouse, nurserymen and seedsmen, Tanner Row, York. Second edition, 1822.

This very interesting catalogue gave the following information:—

Aquilegia:—2 species: *vulgaris*, *canadensis*.

Campanula:—15 varieties.

Delphinium:—*grandiflorum* (fr. Siberia) var. *flore pleno*, var. *chinense*, *elatum*, *azureum*.

Dianthus, including the *Carnation*, 10 varieties, including *alpinus* and *calsius*.

Geum:—*rivale*, *montanum*, *virginicum*.

Hemerocallis:—*flava*, *graminea*, *fulva*, var. *flore pleno*: *japonica*, white flowered; *coerulea*, blue flowered.

Phlox:—18 varieties (but none of the new florist types).

Primula:—15 varieties, of which 9 are varieties (all but one double) of the common *Primrose*: *farinosa*, *auricula*, var. *villosa*, var. *flore albo*, *longifolia*, *marginata*.

Pyrethrum:—2 varieties: *macrophyllum*, *pathonium*.

Lathyrus:—*latifolius*, *sylvestris*, *grandiflorus*; on an interleaved page in writing at 2s. 6d.

Trollius: *europaeus*, *asiaticus*.

Aquatic Plants:—There is a separate list of 19 plants, including *Nuphar luteum*, *Nuphar advena*, *Nymphaea alba*, *Nymphaea odorata*.

Think for a moment of the varied colours now

FIG. 205.—SWEET PEA "DOBBIE'S ORANGE."
R.H.S. Award of Merit on Tuesday last. (See p. 442.)

Iris:—27 kinds, not counting bulbous, of which there are 5, *pallida*, *pallida odoratissima*, *cristata*, *ruthenica*.

Lupinus:—1: *nootkatensis*.

Lilium:—11 kinds: *candidum*, fol. var., *flore stri.* (striped), *flore pleno*, *bulbiferum*, *umbellatum*, *tigrinum*, *pomponium*, *chalconicum*, *Martagon*, *canadense*.

Narcissus:—21 kinds, including *triandrus* and *calathinus*.

Paeony:—12 varieties: *albiflora pleno chinensis*, apparently priced at 7s. 6d., v. *Humei* at 10s. 6d., v. *fragrans* pink at 10s. 6d., *corallina* 9d.

Papaver:—*nudicaule*, *cambricum*, *orientale*

to be found in *Papaver orientale*, and the glorious new Poppies from China.

Consider the *Primulas* from the Himalayas, the Caucasus, the Alps, America, Western China, and elsewhere; we now have a world of rare, fragrant and exquisite flowers. In those days, no *Incarvilleas*, no *Eremurus*, no *Chionodoxas*, no *Gaillardias*, no *Iris Kaempferi*, one *Tritoma* (*Kniphofia*), instead of our present throng, and no *Astilbes*.

Of Alpines, there are few in the 1821 list; there is not, for example, one *Aubrietia*, whereas now, perhaps, we have two dozen varieties; no *Edraianthus*, one *Androsace*—this on the testimony of the York catalogue only.

The advance may be expressed in another way by calling attention not only to the glories of a great garden, such as Great Warley or Aldenham or Gunnersbury, but to what may be seen to-day in a modest country or even town garden (where the owner is an enthusiast who spares no personal trouble). Daffodils of a variety and perfection which would have been deemed impossible a quarter of a century ago; Tulips, dwarf and tall, early and late; Delphiniums and Pyrethrums of undoubted merit; Oriental Poppies, and possibly one of the wondrous forms we owe to the discoveries of Messrs. Forrest, Wilson and Ward; perhaps one or two Primulas from the same marvellous treasure-house; Eremuri, perchance, and Incarvilleas; a few choice fragrant Paeonies; the more easily-grown Lilies, probably including *L. Hansonii* and *L. Henryi*, and even *L. sutchuenense*; a few Phloxes of rich colouring and fragrance; and then, to cheer the waning days of autumn, some of those charming new Michaelmas Daisies, such as *Climax*, *Beauty of Colwall* and *Chastity*.

For these and many another we have to thank the courage, determination and devotion of plant collectors in distant lands, and the patience and skill of the hybridist.

SOME ASPECTS OF MODERN GARDENING.

Mr. R. W. WALLACE, in the course of his paper, said:—

The great and absorbing interest in all that appertains to the garden is mainly concerned—almost entirely concerned—with the planting, growth, and flowering of hardy plants, trees, and shrubs, and, in consideration of the numerous introductions of new plants of all kinds from abroad, and the work of hybridists at home, we now have such a wealth of hardy plants, and a far greater knowledge than formerly as to their proper disposal in the garden, that it is hardly surprising that the energies of the present generation have been directed into developing the culture of the outside garden, as compared with the efforts of our forefathers, who mainly delighted in the culture of greenhouse plants. Hence it is that we have the outdoor garden divided into so many departments, such as the Rose garden, the rock garden, the wild garden, the woodland garden, the Heath garden, etc., and in all these various regions specialists reign, and hooks are written by them and for them.

I fear sometimes we lose sight of that important factor in a rock garden, namely, the proper placing of the stone in relation to the planting. This art was well taught by the late Mr. James Backhouse, almost the pioneer of this movement. Picturesque stones, well and truly placed, with planting duly restrained so that both plants and stone act as a setting to each other, form a pleasant picture, and this, in contrast to what is often seen, masses of plants over-running the stonework until it is almost hidden—plants beautiful in themselves, but possibly used with too free a hand.

I believe the principles governing the planting of the rock garden should be the same as those for other portions of the garden, and, where possible, we should aim at those sheets of colour amid mists of greenery that make Nature's planting in the hills so lovely. But the Alpine children are so numerous, and each has such a fascination of its own in flower or leaf, that it is extremely difficult to draw up a list small enough to satisfy our enthusiasts, although we know that the smaller the number of species and the more restrained the planting, the more natural and beautiful the finished picture will appear.

Wild gardening is the most beautiful and most fascinating form of gardening I know. It is the wise grouping of hardy plants in considerable numbers in bold and irregular formations. How frequently where grass land is available is it left untouched! And yet the open, rough, grassy places adjoining woodland, or the grassy stretches on either side of the entrance drive, or on common lands adjacent, are ideal sites for many of the stronger-growing herbaceous plants.

You will not wish to have a catalogue of suitable plants, but, amongst others, I would emphasise the value of Lupins, both tree and herbaceous; in bold masses, particularly are tree

Lupins useful for clothing rough and unsightly banks. Their growth, peculiar in its semi-drooping habit, seems to fit in so perfectly. Planted in large groups for distant effects at the edge of woodland, and again in odd corners, the mingling of the yellows and whites is very telling, which the addition of the new pale mauves will only make more beautiful. The herbaceous polyphyllus forms are better adapted for massing in groups on level, flat areas, and now that we are getting all shades of blue, pink, and white, and palest lavenders to deepest purple, delightful colour effects can be worked out.

Lupins associated with German Irises in colour schemes form delightful combinations if the colours are chosen carefully, the yellow and brown of the Iris shading into the yellow of the Lupin, and again, the mauve of the tall Iris pallida working up to the deeper blues of the Lupins. Not many Lupins are required, but the occasional use of them with the Iris seems to give strength and height to the scheme. I commend to those who are fond of working out garden plans for themselves to experiment with Irises and Lupins; and here let me give credit where it is due, it is to Miss Jekyll we owe the idea of associating Irises and Lupins.

The Iris family I have mentioned in connection with the foregoing, but they deserve fuller treatment. As a family they are now much in evidence, and are bound to become more so. The vast majority are easy of growth, free-flowering, and quick of increase. For planting in broad masses, I think groups of individual varieties are best. Associate your pale yellows in close proximity to the pale mauves, with an occasional dash of deep purple for contrast.

The old *I. flavescens*, and the newer *Shelford Yellow*, and *Foster's Yellow*, and the pink-mauves *Mrs. Alan Gray*, *Her Majesty* and *Queen of May*, are varieties to be noted as good for this purpose. For deep purples, *Kochi* and *Kharput* are very fine; but nothing exceeds in beauty the fine grouping of the pale lavender of the true *pallida dalmatica*, especially if it can be placed near to a planting of the white *Guelder Rose*. The broad-leaved Irises are generally best massed in large, irregular-shaped groups, rather than in thin lines, and never look better than in irregular beds formed in grass, or in a long, narrow grass-way bordered on either side with groups, or, as at *Clandon Park*, massed in the grass by the lake-side, but well above the water-level; but they may be planted in any open, sunny position with grass surroundings, and in such spots and surroundings they are quite at home.

The Siberian Iris, and its Oriental forms, and the Chinese species *I. Delavayi*, the American forms, such as *I. virginica*, *I. setosa*, and *I. cuprea*, form a group mostly with narrow, grassy foliage and slender spikes. These all luxuriate near water, which seems their natural habitat. The taller groups and later-flowering varieties typical of which are *aurea*, *gigantea*, and many intermediate crosses, with their bold, stiff, spear-like foliage, some 4 to 6 feet high, do not, I think, do so well in too moist a position. They seem to prefer a good, strong soil which is cool and moist, rather than water-logged. In such a soil, massed at intervals with the earlier varieties, they will give a continuity of effect. The Spanish and English Irises are also delightful when grown amidst grassy surroundings, but these are not so easily made permanent occupants in the wild garden, and require occasional renewal.

(To be continued.)

ROYAL COUNTIES AGRICULTURAL.

JUNE 10.—The annual exhibition of the above society opened on the 10th inst., taking place on Southsea Common. The weather was fine though windy, and the attendance of visitors was very satisfactory. The horticultural section was a great success, many of the leading nursery firms having sent attractive and meritorious groups of plants.

Among the horticultural exhibits Sweet Peas were noticeable, especially those sent by Messrs. DOBBIE AND SONS, and Messrs. S. BIDE AND SONS. The former firm showed about three dozen

bunches of excellent quality, with well-developed colour, *Dobbie's Scarlet*, *Melba*, and *Duchess of Portland* being very attractive. A Gold Medal was awarded to this group. Messrs. BIDE showed four dozen bunches, including *Phyllis Bide*, a good new orange-coloured variety. The group was effectively arranged, and secured a Silver-gilt Medal. Messrs. E. W. KING AND CO., Coggeshall, exhibited four dozen bunches of Sweet Peas, including *Anglian Fairy*, *Blush*, *Rosabelle*, and *Lavender George Herbert*. (Silver-gilt Medal.)

Roses were conspicuous both in quantity and quality. Mr. ELISHA J. HICKS, of Hurst, Berks, used as a background for his exhibit large branches of rambling varieties, and filled the foreground with excellent groups of standards and other kinds. In his collection was the new H.T. Mrs. G. Norwood, best described as a pink *Frau Karl Druschki*, and very sweetly perfumed. The new single *Rose Princess Mary*, which possesses the double charm of rich fragrance with intense colour, was also well shown; and *Sarah Bernhardt*, *Papillon*, *Diablo*, *Queen Mary*, *Lady Waterlow*, and *Persian Yellow* were also present in good form. (Gold Medal.)

MESSRS. W. H. ROGERS AND SON, Bassett Nurseries, Southampton, showed four dozen blooms in good exhibition form. Among these were the varieties *Paul Lede*, *Mrs. Hubert Taylor*, *Lyons-Rose*, *Dean Hole*, *Juliet*, and *Marquise de Sinety*. There were also *Clematis* (in pots), and a well-arranged rockery at one end of the tent. (Gold Medal.)

MESSRS. SUTTON AND SONS, of Reading, made an interesting display of *Double Begonias*, *Phlox Drummondii*, *Gloxinias*, *Primula obconica*, *Chrysanthemum coronarium*, *Cineraria stellata*, *Verbenas*, *Nemesias*, and *Salpiglossis*. Vegetables were represented by a collection of thirty dishes of excellent Potatoes, such as *May Queen*, *Carisbrooke Castle*, *Stirling Castle*, *Edinburgh Castle*, *White City*, and *Sutton's Ashleaf*; *Magnum Bonum Cauliflowers*, *Early Giant Peas*, *Carrots*, *Broad Beans*, and *Turnips*. *Cucumbers*, *Melons*, and *Mushrooms* were also well shown. Besides their group Messrs. SUTTON AND SONS also undertook the planting of the beds in the exhibition grounds, which made a very bright display.

Carnations were well displayed by Mr. A. F. DUTTON, of Iver, Bucks, and well deserved the Gold Medal awarded to the group. Carnations were also shown by Messrs. WILLS AND HESKETH, Warsash, and Mr. C. FAY, Testwood Nurseries, Totton.

MESSRS. REAMSBOTTOM AND CO., Geashill, Ireland, sent *Anemones* and hardy flowers, all well grown.

Messrs. B. LADHAMS AND CO., Shirley, constructed an old English garden, surrounded by stone walls, effectively planted with a variety of the favourite hardy plants. They were awarded a Gold Medal.

Messrs. STUART LOW AND CO., Enfield, showed an interesting group of well-flowered Orchids, and also Carnations and Roses.

Messrs. JARMAN AND CO., Chard, exhibited a collection of *Centaureas*, white, lilac and yellow. These, together with a small group of Sweet Peas, *Pelargoniums*, and *Violas*, were awarded a Silver Medal.

Miss R. C. WHEELER AND CO., Elmswood Nursery, Cosham, showed a prettily-designed and planted rockery.

Messrs. H. B. MAY AND SONS, Chingford, exhibited a large and varied group of Ferns, *Lantanas*, and *Heliotropes*, for which they gained a Gold Medal.

THE GUILDFORD HARDY PLANT NURSERY showed cut flowers and choice Alpines, and were awarded a Silver Medal.

Messrs. WATERER, SONS, AND CRISP, of Bagshot, showed *Rhododendrons* and *Kalmias* in an effective manner at one end of the tent. Their group was awarded a Gold Medal.

Messrs. E. HILLIER AND SON, Winchester, exhibited new shrubs, hardy flowers, and Water Lilies.

The only exhibitors of vegetables alone were Messrs. TOOGOOD AND SONS, of Southampton. They showed an extremely attractive group of Tomatoes, Cauliflowers, Broad Beans, Peas, Lettuce, Potatoes, Onions, Radishes, Vegetable Marrows, Beetroots and Carrots, which well deserved the Gold Medal awarded.

YORKSHIRE GALA.

JUNE 17-19, 1914.

THE fifty-sixth annual Yorkshire flower show and gala opened on Wednesday last in the Bootham Park, York, in glorious summer weather, and continued for three days. These exhibitions rank with the best shows held in the provinces, and the display this year was equal, at the least, to anything the broad county has witnessed. The exhibits were accommodated in one large tent, similar to that at the Chelsea shows, and it was probably due to this fact that the event was so successful. The interior of the large canvas structure was in marked contrast to that of the usual flower show tent on a hot day. The atmosphere was cool, and there was plenty of light to show off the flowers to advantage. The exhibits, if we except fruit, were of exceptional quality, and especially those of Roses, Sweet Peas, Orchids, groups of plants, and hardy flowers. The committee is to be congratulated on the progressive spirit displayed in the management, and the secretary, Mr. Fred Arey, deserves the thanks of all.

Groups.

The most important class was that for a group of miscellaneous plants, in or out of bloom, arranged for effect, and occupying a space of 300 square feet. The prizes offered were of the total value of £70, the 1st prize being £20.

Five exhibits were forthcoming, and all were meritorious. The 1st prize was awarded to J. PICKERSGILL, Esq., Bardon Hill, Weetwood, Leeds (gr. Mr. J. Donoghue). The design was diamond-shaped with a central cross-bar on pillars carrying Roses, Ferns, Codiaeuums (Crotons), Odontoglossums, and a magnificent Palm in the centre. This provided a good "middle," but the system (now a common feature in these classes at shows) is unnatural and too formal. An old fallen tree trunk may have suggested the idea, but centrepiece and matched corner foils are not nature. However, the quality of the various plants deserves the highest praise, whether Orchids, Roses as Standards, Kalanchoe flammea, Anthuriums, Crotons, Caladiums, Dracaenas, or Alcaicias, and each plant had its full value for display. The 2nd prize was awarded to Mr. W. A. HOLMES, nurseryman, Chesterfield, who also employed a central archway crowned with a tall palm. The Crotons in this collection were splendid, and there were also good Roses, Liliums, Lantanas, Spiraeas, Caladiums, Coleuses, Dracaenas, Ferns and other species, making a beautiful assemblage of fine foliage and bright flowers; 3rd, Messrs. R. SIMPSON AND SON, Selby; 4th, Mr. F. H. WARD, York.

The class for a group of hardy plants and flowers, with background of decorative plants, Bamboos, with pool of water, Nymphaeas, water plants, etc., arranged for natural effect on the ground level, took the place of the old rock garden class. The 1st prize was awarded to Messrs. J. BACKHOUSE AND SON, LTD., York, for an exhibit which was rather heavy in design and a little overdone with greenery at the back. But there were many excellent features, including the waterfall and stream, and the colonies of *Cypripedium Calceolus*, *Primulas*, *Ramondias*, *Saxifraga pyramidalis*, and other Alpines that seemed quite at home. The 2nd prize was awarded to Mr. S. PICKERING, Clifton, Yorks, who also "banked" his exhibit and crowned it with Bamboos, *Acer Negundo*, and other graceful trees. There was also a dripping stream and pool, the latter planted with *Nymphaeas*. The whole was plentifully furnished with plants of low growth, including Ferns. 3rd, Messrs. ARTHURDALE AND SON, Sheffield, with many plants from the herbaceous border—*Oriental Poppies*, tall *Verbascums*, *Kniphofia*, *Liliums* *Spiraeas*, *Roses*, and others of this class; 4th, Mr. T. H. GAUNT, Farsley, Leeds, who was nearest to nature in the arrangement of his exhibit, but not strictly in keeping with the schedule.

The groups of bedding plants staged in Class 5,

either semi-circular or corner-shaped, were not remarkable. The 1st prize was awarded to Mr. W. PYBUS, Monkton Moor, near Leeds, for an oval bed with panels of scarlet *Pelargoniums*, *Saxifraga pyramidalis* (exceptionally fine spikes), golden *Calceolarias* and *Marguerites*, with a border of *Campanula carpatica*; 2nd, CLIFTON FRUIT AND VEGETABLE CO. This exhibit formed the central bed around the four exhibits in the next class; 3rd, Mr. T. M. PETCH, Bridlington, for a mixed group.

There was another class for a group of bedding plants, and this was much the better. There were four exhibits, and the 1st prize was awarded to Messrs. HARKNESS AND CO. for a bright bed of scarlet *Salvias*, *Pelargoniums*, *Fuchsias*, *Violas*, *Hydrangeas*, and *Schizanthus retusus* with foils of weeping *Roses*; 2nd, Mr. T. M. PETCH. For a collection of plants, in or out of bloom, and of cut flowers arranged for effect, the 1st prize was awarded to Messrs. J. CYPHER AND SONS, who employed choice Orchids, with a few *Anthuriums*, *Crotons*, *Ferns*, *Asparagus*, and other fine foliage plants; 2nd, Mr. HOLMES, Chesterfield, with stove and greenhouse plants and flowers arranged very pleasingly; 3rd, Mr. J. PICKERSGILL, Leeds.

In the smaller class, for a collection arranged on a space 12 feet by 6 feet, Mrs. WHITEHEAD, Deighton Grove, York, excelled with a commendable group, well arranged; 2nd, J. PICKERSGILL, Esq.; 3rd, W. D. ARTON, Esq., Rawdon, Leeds (gr. Mr. F. Howland).

SPECIMEN PLANTS.—The 1st prize in the class for three ornamental fine foliage or variegated plants was won by Messrs. J. CYPHER AND SONS, who also showed best in the class for three *Codiaeuums* (Crotons). The best single specimen *Codiaeum* was shown by Messrs. R. SIMPSON AND SON, Selby.

Orchids and other Exotics.

The competitive classes for Orchids were not so extensively represented as usual.

In the class for a table of Orchids, 12 feet by 5 feet, Messrs. J. CYPHER AND SONS, Cheltenham, were awarded the 1st prize for a finely arranged exhibit, which included *Laelio-Cattleya Canhamiana*, *L.-C. Aphrodite*, *C. Whitei*, a grand plant of *C. Warszewiczii*, fine plants of *Miltonia vexillaria* and *Thunia Marshalliana*. Messrs. CYPHER AND SONS were also placed 1st in the class for twelve Orchids in bloom. W. P. BURKINSHAW, Esq., Hessle, Yorks (gr. Mr. J. T. Barker), was a close 2nd, and Mr. J. SUNLEY, South Mitford, 3rd. In the class for six Orchids Messrs. CYPHER AND SONS again excelled. For three Orchids in bloom Mr. W. P. BURKINSHAW was 1st, showing *Laelio-Cattleya Lady Miller*, a grand variety of *Miltonia vexillaria*, and *Laelio-Cattleya Canhamiana* variety *Amelia*.

In the open class for a new or rare Orchid Mr. BURKINSHAW won the 1st prize with the lovely *Cattleya Mendellii* *White Queen*, having only a faint tint of rose on the front lobe of the lip.

In the three classes for Orchids open only to amateurs Mr. BURKINSHAW won all the 1st prizes.

PELARGONIUMS.—The majority of these plants were accommodated in an overflow tent. There were five classes, one for a collection of show varieties, arranged for effect with foliage plants, including Ferns, on a table 8 feet by 5 feet. The 1st prize was awarded to a local grower, Mr. H. LEETHAM (gr. Mr. R. Keighley); 2nd, Messrs. GODFREY AND SON, Exmouth. The trained specimen Zonal varieties were as good as we have seen them in former years, but they do not attract so much interest as formerly, and we understand that the classes will be discontinued. Mr. H. PYBUS, Monkton Moor, Leeds, repeated his successes of former years. He was placed 1st for (a) 12, (b) 6, and (c) 3 Zonal, Nosegay, or hybrid Nosegay varieties, distinct, Mr. J. W. CLARK, York, following in each case. These exhibitors were also awarded the 1st and 2nd prizes respectively in the class for six double-flowered *Pelargoniums*, distinct, the plants being the best in the section.

CARNATIONS.—The schedule included a class for a group of Carnations in bloom, arranged in a space 12 feet by 6 feet. Of the two exhibits staged the better was shown by Mr. W. LANGSTAFFE, whose plants were well flowered, compact, and represented a good selection of colours. Mr. J. PICKERSGILL was placed 2nd for *Souvenir de la Malmaison* varieties of exceptional vigour.

BEGONIAS.—The finest Begonias in the show were exhibited by Messrs. BLACKMORE AND LANGDON, Bath, in the class for a group of tuberous-rooted varieties arranged on the floor in a space of 100 square feet. Mr. THOS. WINN, York, was successful in the classes for (1) a group measuring 12 feet by 2 feet, and (2) the best and most distinct varieties in flower.

Capt. EDWYN WALKER, York (gr. Mr. H. Clark), showed the best group of *Gloxinias*, and the best group of *Calceolarias*, and was awarded the 1st prizes.

Roses.

Mr. W. TODD, York, excelled easily in the class for a collection of Roses in pots. Hybrid Perpetuals and Hybrid Teas were arranged in a group with Ramblers above them, and pretty dwarf *Polyantha* varieties as an edging. None of the plants was named. 2nd, Mr. W. LANGSTAFFE, York.

For a group of Roses, not fewer than 20 pots, Mr. TODD again excelled, and Mr. LANGSTAFFE was again placed 2nd.

The best table of Roses, 6 feet by 4 feet, was shown by Messrs. W. and J. BROWN, Peterborough. The space was too limited to obtain a good result, but Messrs. BROWN made the most of their possibilities and showed how well good blooms can be exhibited in a small space. In the centre was a splendid vase of *Lady Pirrie* variety. 2nd, Mr. GEO. PRINCE, Oxford, who made a feature of the variety *Juliet*.

CUT BLOOMS.—There were three exhibits in the class for 72 blooms in not fewer than 36 varieties. The 1st prize was awarded to Messrs. JARMAN AND CO., Chard, for massive, well-coloured flowers that remained fresh under the trying heat. Notable varieties were *G. C. Waud*, Mrs. E. Mawley, Dean Hole, Mme. J. Gravereaux, Ulrich Brunner, *Lady Ashtown*, *Hugh Dickson*, and *Lady Helen Vincent*. 2nd, Messrs. R. HARKNESS AND CO., Hitchin; 3rd, Mr. HARRY RICHARDS, Warsash.

There were four competitors in the class for 48 blooms in not fewer than 24 varieties, and here Messrs. J. BURRELL AND CO., Cambridge, carried off the 1st prize with *Hugh Dickson*, Mrs. J. H. Welch, *Ethel Malcolm*, Dr. O'Donel Brown, Mrs. Foley Hobbs, Mrs. Ed. Mawley, *Souvenir de Pierre Notting* and *Maman Cochet* as his best blooms. 2nd, Messrs. JARMAN AND CO., Chard; 3rd, Messrs. HARKNESS AND CO., Hitchin.

For 36 blooms Messrs. W. and J. BROWN, Peterborough, excelled with splendid flowers of Mrs. W. H. Rowe, Mme. Jules Gravereaux, J. B. Clark, Mrs. A. Carnegie, C. W. Cowen, *Ethel Malcolm*, Mrs. W. H. Rowe, Molly S. Crawford, John Cuff and others. 2nd, Messrs. R. HARKNESS AND CO., with small but refined blooms; 3rd, Messrs. J. BURRELL AND CO.

There was a keen competition in the smaller classes. For 24 blooms, distinct, Mr. GEO. PRINCE, Oxford, won the 1st prize with the best blooms in the show. This select exhibit included Mrs. Amy Hammond, Mme. Jules Gravereaux, Leslie Holland, *Lyon Rose*, *Souvenir d'un Ami*, *British Queen*, Mme. Mélanie Soupert, *Frau Karl Druschki*, and Mrs. Foley Hobbs. 2nd, Messrs. J. BURRELL AND CO.; 3rd, Messrs. W. and J. BROWN.

For 18 distinct varieties the prizes were won by Messrs. GEO. PRINCE, Messrs. W. and J. BROWN, and Messrs. J. BURRELL AND CO. in this order. In the two Amateur Classes for Roses Mr. W. HUTCHINSON, Kirby Moorside, won both the 1st prizes.

SWEET PEAS.—The Sweet Peas were notably good, both in the Competitive Class and the traders' collections. There was only one class

and the schedule called for 18 bunches of distinct varieties, arranged in a space 12 feet by 4 feet, on three-tier staging. Four good exhibits were forthcoming, and the 1st prize was awarded to Messrs. E. W. KING AND CO., Coggeshall, their varieties being Elfrida Pearson, Illuminator, Mrs. Cuthbertson, Princess Mary, Phyllis, Rosabelle, Bertrand Deal, Margaret Atlee, Anglican Orange, Inspector, Anglican Fairy, King Manoel, Anglican Cream, Thos. Stevenson, Lavender Geo. Herbert, R. F. Felton, Anglican White and Hercules; 2nd, Messrs. HOBBIES, LTD., Dereham, Norfolk.

RHODODENDRONS.—There was a class for a group of Rhododendrons in bloom occupying a space not exceeding 200 square feet. There were only two exhibits, and Messrs. WATERER, SONS AND CRISP, LTD., won the 1st prize easily with superb plants in pots, the exhibit being much brighter than that of their competitors, Messrs. KENT AND BRYDON, Darlington.

Messrs. WATERER's plants were all in pots and small, but they were flowering magnificently. Notable varieties were Mrs. John Kelf, warm rose; Warrior, huge crimson trusses; Gomer Waterer; Sunshine, old rose with gold blotch; and the new Duchess of Teck, a pink Gomer Waterer. Messrs. KENT AND BRYDON were awarded the 2nd prize.

Hardy Flowers.

The exhibits of hardy flowers arranged on tabling made a notable feature along one side of the tent. The competition was keen, but Messrs. HARKNESS AND SONS showed decidedly best, and were awarded the 1st prize. Oriental and Iceland Poppies, Paeonies, Irises, Lupins, Scarlet Geums, Gladiolus Blushing Bride, and Delphiniums were the more notable subjects; 2nd, Messrs. G. GIBSON AND CO., Bedale; 3rd, Messrs. GODFREY AND SON.

For a collection of 24 bunches Messrs. HARKNESS again excelled, and Messrs. G. LONGSTER AND SONS, Derwent, were placed 2nd.

In the smaller class for 12 bunches the prizes were awarded to the Marquis of NORTHAMPTON, Castle Ashby (gr. Mr. A. R. Searle), and Mr. HUTCHINSON respectively.

The class for a collection of hardy herbaceous perennials, plants or cut flowers, or both, arranged in a natural manner on the ground in a space of 300 square feet, provided a splendid colour effect. But the exhibitors aimed at imposing collections, and lightness and gracefulness were sacrificed to the desire to include something of everything; consequently the effects were anything but "natural." The local nurserymen, Messrs. J. BACKHOUSE AND SON, were easily first amongst four exhibitors, for their style of grouping was best and the quality of their flowers superb, but tall standard Roses should certainly not be included in a collection of hardy herbaceous perennials. These, with tall Eremuri, served as foils to masses of Anchusa, Paeonies, Liliums, Pyrethrums, Verbascons, Irises, Gaillardias, Gladioli, and a host of other hardy border flowers. 2nd, Messrs. ARTINDALE AND SON, who massed their flowers, making a wonderful group of colour, and having almost everything the flower border affords at this season. 3rd, Messrs. GIBSON AND CO., Bedale; 4th, Messrs. HARKNESS AND SONS.

Fruit and Vegetables.

York Gala has no great reputation as a fruit and vegetable show, and on this occasion the exhibits were very poor. There was no entry in the class for a decorated table of ripe fruit, and only one very poor exhibit in the class for a collection of 10 kinds. But two good exhibits were forthcoming in the class for a collection of six kinds, J. BRENNAND, Esq., Thirsk (gr. Mr. J. Hathaway), winning the first prize with choice Nectarines, Royal George Peaches, Brown Turkey Figs, Black Hamburg Grapes, and a fine Melon. Mr. FRANK PLUMER, Market Weighton (gr. Mr. R. J. Vaughan), was placed 2nd, with Figs, Nectarines, Peaches, Melon, and Grapes (Black Hamburg and Foster's Seedling). Nectarines (Lord Napier) were splendid.

For a collection of four kinds, Sir ROBERT WALKER, Bart., York (gr. Mr. James Folkard), excelled with good Black Hamburg Grapes, small in berry, but large bunches; Laxton's Leader Strawberries, Lord Napier Nectarines,

and a Melon; 2nd, W. D. CLIFF, Leeds (gr. W. N. Hague), whose best dish was of Peaches.

The Marquis of NORTHAMPTON, Castle Ashby (gr. Mr. A. R. Searle) showed the best Peaches, and Mr. J. W. DENT the best Nectarines.

Sir ROBERT WALKER, York, had the finest white Grapes in the variety Buckland Sweetwater and Lady HAWKE the best two bunches of Black Hamburg variety.

In the Melon classes the 1st prize winners were (scarlet-fleshed) Marquis of NORTHAMPTON, (green-fleshed) Lord DERAMORE, and (white-fleshed) ROSALIND Countess of CARLISLE (gr. Mr. Sutton).

There were also classes for Figs, Cherries, Strawberries, and Tomatos, in which the Marquis of NORTHAMPTON and Mr. JOHN BRENNAND showed successfully.

VEGETABLES.—The Marquis of NORTHAMPTON won the 1st prizes in both Messrs. Sutton and Sons' and Messrs. Ed. Webb and Sons' classes for collections of six distinct kinds of vegetables, showing good Peas, Tomatos, Cauliflowers, Beans, Onions, and Carrots. Mr. A. BLAKEY, York (gr. Mr. Howden), was placed 2nd in both classes.

Non-Competitive Exhibits.

Messrs. R. WALLACE AND CO., Colchester, staged a floor group of hardy flowers. The centre was comprised of Eremuri and Delphiniums, with a centre-piece of Bamboos. Around these were arranged masses of Campanulas, Paeonies, Lilies, Ixias, Spanish Irises, Heucheras, and other kinds. (Large Gold Medal.)

Messrs. SUTTON AND SONS, Reading, filled a large table with flowers, fruits, and vegetables—an exhibit of high-class produce, shown in the most attractive style. Sweet Peas were interspersed amongst the fruits and vegetables, and at the back, against a black velvet ground, were beautiful vases of Lupins, Poppies, Delphiniums, Pyrethrums, and Aquilegias, whilst in the centre was a mass of fine Gloxinias. (Large Gold Medal.)

Messrs. JAMES CARTER AND CO., Raynes Park, filled a table, 50 feet frontage by 5 feet, with flowers and vegetables. The flowers comprised Spanish Irises and Sweet Peas. The vegetables were arranged in the centre, and included Perpetual Dwarf Beans, Harvestman and Springtide Peas, Improved Telegraph Cucumbers, Golden Butter Beans, Duke of York Tomatos, Springtide Cabbage, Marrows, Lettuces, Turnips, Carrots, Asparagus, Mushrooms, Aubergines and other kinds. (Large Gold Medal.)

Messrs. ED. WEBB AND SONS, Wordsley, Stourbridge, showed half-circular groups of flowers and vegetables against a green cloth background. In the centre was an imposing exhibit of vegetables and Sweet Peas, separated on either side from masses of Cinerarias and Calceolarias by blocks of Schizanthus and Star Primulas respectively. (Large Gold Medal.)

Messrs. DOBBIE AND CO., Edinburgh and Mark's Tey, showed Sweet Peas, their exhibit of these flowers being unrivalled in the show. Such beautiful varieties as Mrs. Cuthbertson, Dobbie's Orange, Elfrida Pearson, Illuminator, New Marquis, King White, and Edson Beauty were all of superb quality. In addition to Sweet Peas this firm showed Spanish Irises in variety. (Large Gold Medal.)

Messrs. W. CUTBUSH AND SON, Highgate, had a delightful floor group of Roses, Carnations, Liliums, Hydrangeas, Verbenas, Crassulas, and other flowers, for which a Large Gold Medal was awarded.

Messrs. KELWAY AND SON, Langport, Somersetshire, showed fine Paeonies, Delphiniums, Gaillardias, Lupins, and other hardy flowers. The Paeonies were exceptionally fine. (Gold Medal.)

Messrs. JOHN PEED AND SON, West Norwood, arranged an oval bed with hybrid Streptocarpuses, relieved with Ferns and Palms and bordered with Gloxinias. (Silver-gilt Medal.)

Messrs. STUART LOW AND CO., Enfield, showed Roses and Carnations, both of superb quality. (Large Silver-gilt Medal.)

Messrs. S. BIDE AND SONS, LTD., Farnham, exhibited a large number of Sweet Peas, representing the pick of the choicer sorts in cultivation. (Gold Medal.)

Messrs. GUNN AND SONS, Olton, Warwickshire, showed border Phloxes; Duchess of Wellington, mauve; Mauve Queen, "French" grey;

Rijnstroom, salmon; and Flora, white, are a selection of the newer sorts exhibited. (Large Silver-gilt Medal.)

Messrs. JAMES CYPHER AND SONS, Cheltenham, filled a space of 600 square feet with flowering and foliage plants, making one of the most imposing exhibits in the show. (Large Gold Medal.)

Messrs. MANSELL AND HATCHER, Rawdon, Leeds, exhibited a group of Orchids for which a Large Gold Medal was awarded. The centre consisted of fine plants of Renanthera lmschootiana overhung with finely-flowered spikes of Phalaenopsis Rimstadiana on each side of the centre. The groundwork consisted principally of Miltonia vexillaria and hybrid Cattleyas and Laelio-Cattleyas, Vanda Teres and Odontoglossums.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Gold Medal for a group consisting of fine plants of Miltonia vexillaria, several varieties of Laelio-Cattleya Fascinator, L.-C. Aphrodite, L.-C. Canhamiana alba, C. Warscewiczii, C. Mossiae Wageneri, C. Gaskelliana alba, choice plants of Odontoglossum crispum and hybrids.

Messrs. KENT AND BRYDON, Darlington, were awarded a Large Gold Medal for a rock garden of large size. The arrangement pleased us, for the rockery was not over-planted. It was designed with old stratified sandstone, a stream and pool of water forming part of the scheme. (Large Gold Medal.)

Mr. CLARENCE ELLIOTT, Stevenage, arranged a rockery as a table exhibit. (Large Silver Medal.)

A rockery was also exhibited by Messrs. BROADHEAD AND SON, for which the award of a Large Silver-gilt Medal was made.

Mr. A. F. DUTTON, Iver, Buckinghamshire, showed Carnations in baskets. (Gold Medal.)

Messrs. ARTINDALE, Sheffield, showed Carnations, Violas and Sweet Peas. (Silver-gilt Medal.)

Messrs. HOBBIES, LTD., Dereham, Norfolk, were awarded a Gold Medal for a collection of Sweet Peas of fine quality.

Hardy flowers were shown well by Messrs. JAMES COCKER AND SONS, Aberdeen. (Silver-gilt Medal.)

Messrs. YOUNG AND CO., Hatherley, arranged beautiful Carnations of the Perpetual-flowering type on a table. (Gold Medal.)

Messrs. ALEX. DICKSON AND SONS, Belfast, exhibited Sweet Peas of splendid quality together with Spanish Irises. (Gold Medal.)

Mr. C. ENGELMANN, Saffron Walden, showed Perpetual-flowering Carnations in variety. (Silver-gilt Medal.)

Messrs. BLACKMORE AND LANGDON, Twerton-on-Avon, Bath, showed Delphiniums. (Silver-gilt Medal.)

Mr. W. R. TRANMER, Cottingham, Hull, staged Pansies and Violas, also seedlings of Viola cornuta, together with a selection of hardy border flowers. (Silver Medal.)

Mr. H. N. ELLISON, West Bromwich, showed Ferns and small plants of Cacti in bowls and pots. (Silver Medal.)

Miss H. HEMUS, Upton-on-Severn, was awarded a Silver-gilt Medal for Sweet Peas.

Messrs. R. H. BATH, LTD., Wisbech, showed superb Paeonies in a general collection of border flowers. (Gold Medal.)

Messrs. JAMES BACKHOUSE AND SON, York, staged a solid, four-sided exhibit of Roses, Hydrangeas, Coleus, Spiraeas, Carnations, and other flowers, a massive but imposing exhibit. (Large Gold Medal.)

Messrs. DICKSONS, Chester, exhibited border flowers of good quality, the majority being of Paeonies and Delphiniums. (Large Silver-gilt Medal.)

Messrs. E. J. BATCHELOR AND SONS, Harrogate, showed exotic Ferns, in which varieties of Nephrolepis predominated. (Silver-gilt Medal.)

Roses in great variety were shown by Messrs. W. AND J. BROWN, Peterborough, and this firm also exhibited hardy border flowers. (Large Silver-gilt Medal.)

Mr. GEO. PRINCE, Oxford, was awarded a Silver Medal for Roses.

Mr. W. LAWRENSON, Yarnon-Tees, showed Perpetual-flowering Carnations and hardy border flowers. (Silver-gilt Medal.)

Messrs. G. LONGSTER AND SONS, Malton, showed hardy perennial flowers in variety.

Messrs. JARMAN AND CO., Chard, showed Cen-

taureas and Zonal-leaved Pelargoniums. (Silver Medal.)

Mr. G. W. MILLER, Wisbech, exhibited hardy border flowers in variety. (Silver Medal.)

Messrs. E. W. KING AND Co., Coggeshall, Essex, showed Sweet Peas in a novel manner, some arranged on arches, others on tall stands with beds on the floor. (Gold Medal.)

R. C. VYNER, Esq., Newby Hall, Ripon (gr. Mr. G. Watson), staged a collection of succulents, one of the finest exhibits of these plants we have seen at a show. (Gold Medal.)

Messrs. B. LADHAMS, LTD., Shirley, Southampton, staged border flowers in variety, including hybrid Pinks, for which this firm is famed. (Silver Medal.)

Messrs. CHAS. SIMPSON, LTD., York, showed fruits and flowers, also floral designs, for which a Silver-gilt Medal was awarded.

Messrs. RICH AND Co., Bath, showed border flowers and Roses. (Silver Medal.)

Mr. G. YELD, York, showed hybrid Irises and Hemerocallis. (Silver-gilt Medal.)

A Silver Medal was awarded to Messrs. GODFREY AND SONS, Exmouth, for an exhibit of hardy flowers.

MARKETS.

COVENT GARDEN, June 17.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

REMARKS.—Large supplies are arriving daily, and there is almost a glut of coloured Iris, Sweet Peas, Iceland Poppies and coloured Gladioli. All coloured flowers are more plentiful and cheaper than white varieties. Coloured Pyrethrum are now over, and the double white varieties less plentiful; white Stock and white Pinks (Her Majesty) are coming to hand in good condition. There is an abundant supply of Roses, those mostly in demand being Frau Karl Druschki, Liberty, Richmond, Mme. Abel Chatenay, Melody and Sunburst. Among the new arrivals this week are Canterbury Bells, white, pink and blue; Coreopsis, Delphiniums, Gaillardias, Nigellas (Love-in-a-mist) and Scabious; while pink and white Gypsophilas are exceptionally good and cheap.

Dracena, green, per dozen	10 0 12 0	— Ivyleaf, 48's	6 0 9 0
Erica Cavendishii 21 0 24 0		Phoenix rupicola, each	2 6 21 0
— magnifica, 48's 15 0 18 0		Rose, Rambler, each	4 0 10 0
Ferns, in thumbs, per 100	8 0 12 0	Saxifraga pyramidalis, per doz.	15 0 18 0
— in small and large 60's	12 0 20 0	Spiraea japonica, per dozen pots	6 0 8 0
— in 48's, per dozen	5 0 6 0	Stocks, white, 48's per dozen	6 0 8 0
— choicer sorts, per dozen	8 0 12 0	— pink	6 0 8 0
— in 32's, per doz.	10 0 18 0	— red	6 0 8 0
Fuchsias, 48's, per dozen	7 0 9 0	Verbenas, Miss Willmott, 48's, per dozen	8 0 9 0
Geonoma gracilis 60's per dozen	6 0 8 0		
— larger, each	2 6 7 6		

REMARKS.—Hydrangea paniculata is selling well, but the supply is small. The white and blue varieties are more popular than the pink. Other plants which are selling well are Crassulas, scarlet and pink; Verbenas (Miss Willmott), white Marguerites, pink Spiraeas, and Rambler Roses, all of which are arriving in good condition. The trade in flowering plants is still good, and Ferns are gradually improving in quality.

Pineapples, St. Michael	3 0 3 6	— Kent, pecks	3 0 4 0

REMARKS.—Arrivals from Australia this week amounted to about 128,000 packages, the bulk of the cargo consisting of Apples. There are large consignments of Strawberries from all sources, and an unusually good supply of Peaches. Nectarines and green Figs are still scarce. The supply of Melons exceeds the demand, and of Grapes there are plentiful supplies of both Black Hamburg and Muscat of Alexandria. Early English Cherries are now available, and Apriots, Cherries, Cantaloupe Melons, and Black and Red Currants are arriving daily from the Continent.—E. H. R., Covent Garden, June 17, 1914.

		Watercress, per doz.	0 4 0 6

REMARKS.—This week there are increased supplies of Tomatos and Cucumbers; Peas and Broad Beans are daily more plentiful. Cabbage and Parsley are scarce; English and Dutch Cauliflowers are fairly plentiful, and the supply of Vegetable Marrows is increasing. The supply of Asparagus is good for the time of year, and Mushrooms are becoming more plentiful.—E. H. R., Covent Garden, June 17, 1914.

Old Potatoes.

Kents	8 6 10 0		

REMARKS.—Stocks of old Potato are nearly finished. Trade in new Potatoes is fairly good, and their prices are much lower. A good supply of new tubers is arriving from Kent growers.—Edward J. Neuborn, Covent Garden and St. Pancras, June 18, 1914.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending June 17, 1914.
Another Welcome Fall of Rain.—This was a warm week, and more particularly during the daytime. On four days the temperature in the thermometer screen rose above 75°, and on the warmest of those days the highest reading was 75°. The nights were, as a rule, only moderately warm for the time of year, and on one night the exposed thermometer fell to within 6° of the freezing-point. The ground is now 1° warmer at 2 feet deep, and 2° warmer at 1 foot deep, than is seasonable. Rain fell on only one day, but on that day to the depth of over 1/2 inch, bringing up the total quantity for the seven days ending the 11th inst. to 1 1/2 inches—equivalent to 6 gallons of rain on every square yard. Of that amount 3 1/2 gallons have come through the bare soil gauge, but none through that on which short grass is growing, showing how dry the ground had previously become. The sun shone on an average for 8 1/2 hours a day, which is 2 1/2 hours a day longer than is usual at the same period in June. On two days the sun was shining brightly for over twelve hours a day, but on two other days for less than three hours a day. Light airs and calms alone prevailed during the week, these light airs coming almost exclusively from some point between north and east. There was about a seasonable amount of moisture in the air at three o'clock in the afternoon.—E. M., Berkhamsted, June 17, 1914.

Obituary.

GEORGE GORDON, V.M.H.—It is with deep regret that we record the death of Mr. George Gordon, who was for 25 years editor of the *Gardeners' Magazine*. The announcement of his retirement from the editorial chair in November last was received with surprise by his large circle of acquaintances and all but his most intimate friends, for Mr. Gordon, in spite of the fact that he had passed the allotted three score years and ten, appeared to be still hale and vigorous. But he was stricken with cancer on the liver, and died on June 14. The son of a gardener Mr. George Gordon was cradled in horticulture, and throughout his life his interests were centred in the profession, for he had no hobbies except those directly connected with his work. Always eager in the pursuit of knowledge he was, when well over 40 years of age, attending classes at the Birkbeck Institute, then accompanied by his eldest son, who is now in the Civil Service. He was a skilful photographer, as the many illustrations from his camera which have appeared in our contemporary testify. Quite lately he studied colour photography, and possessed many autochromes of more than average merit. Tall and broad-shouldered he was fortunate in possessing a sound constitution, which enabled him to work hard and almost tirelessly. When over 60 years of age he judged at the York Chrysanthemum Show, took notes of the exhibits, elaborated them during the train journey to London, handed his report to the printers on his arrival, and then proceeded to Folkestone to deliver a lecture in the evening of the same day. He was born 72 years ago at Frogmore Hall, Hertfordshire, where his father, who was a very successful grower and exhibitor of fruit, was head gardener, and from whom he imbibed the first principles of gardening. His first situation away from home was as journeyman at High Leigh, Hoddesdon, in a garden famed for its collections of Orchids and other glass-house plants. After three years, part of the time as foreman, he was appointed fruit and vegetable foreman at Duncombe Park, Helmsley, Yorkshire, where he also became so interested in agriculture that for a time he contemplated following the sister craft, but an appointment as gardener at Norbiton Hall, Kingston, brought him south and decided him to continue gardening. Shortly afterwards the Norbiton Hall estate was sold, and Mr. Gordon was engaged to take charge at The Elms, Hampton Wick. At this time he was only 23 years of age, but he soon established a reputation as a plant exhibitor. His contributions to the *Gardeners' Magazine*, commenced at this time, induced the late Mr. Shirley Hibberd to invite him to join the staff of that journal as assistant editor, and on the death of that famous horticulturist, some 20 years later, he succeeded him as editor. His great interest in Chrysanthemums and Dahlias are well known to the present generation. He was one of the promoters of the first Fruit Conference, which was held at the Crystal Palace on September 7 and 8, 1884. This conference inspired the formation of the British Fruit Growers' Association, and Mr. Gordon was elected vice-chairman. In the early autumn of 1890, in company with Mr. Lewis Castle, hon. secretary of that Association, Mr. Gordon spent nearly a month in visiting the counties of Antrim, Londonderry, Cork, Kerry and Waterford to investigate the fruit industry of Ireland, and his report attracted a considerable amount of attention and criticism, but it bore valuable fruit. Besides having been a member of the committee of the National Chrysanthemum Society for 13 years he was elected a vice-president of the National Rose Society in 1890, and had held a seat on the R.H.S. Floral Committee since 1891. He was one of the promoters of the National Sweet Pea Society. In 1897 he was one of the first sixty to be awarded the Victoria Medal of Honour, and after having been a vice-president of the National Dahlia Society from 1891 to 1912 became its president. At the time of his death he was vice-chairman of the Horticultural, Arboricultural and Forestry Committee of the Anglo-American Exposition at the White City, Shepherd's Bush. His services were in great

request as a judge at flower shows, and on six occasions he was a member of the jury at the Ghent Quinquennial Exhibitions, and acted similarly at Antwerp, Haarlem and Hamburg. Of his many writings the most important are *Dahlias* (Present-Day Gardening Series), *The Book of Shrubs*, and *The Wasted Orchards of England*. Mr. Gordon entertained strong sympathies for the gardener, and was a member of the Committee of the Royal Gardeners' Orphan Fund, of which body he was an influential member. We tender our deep sympathies to his widow, two sons and daughter.

A. F. GARDINER.—Mr. A. F. Gardiner, for 36 years gardener at The Grove, Dumfries, died in Dumfries on the 13th inst. Deceased was a good gardener, and much trusted by his employers. He was 67 years of age, and had lived in retirement for the past three years.

CARNATION FOLIAGE TURNING A YELLOW COLOUR: *Foreman, Blackburn.* The plants are not diseased; the yellow colour in the leaves has resulted from unhealthy root-action caused by the presence of too much moisture in the soil.

THE LATE GEORGE GORDON, V.M.H.

CHIONODOXA WITH ABNORMAL ROOT: *H. and Son.* The swollen root has the appearance of a dropper bulb, but droppers have never been described for Chionodoxa. The structure concerned arises from the same position as a dropper. But its anatomical structure does not agree with that of a dropper, which is a shoot or leaf or both. This organ in Chionodoxa has root structure. Therefore it is merely a fasciated root.

FIG LEAVES DISEASED: *R. G.* The disease from which your Fig trees are suffering is caused by *Cercospora Bolleana*, a parasitic fungus. Collect and burn all diseased leaves and fruits, and spray the trees with diluted Bordeaux mixture. If the trees are badly affected, root them up and destroy by burning, afterwards planting healthy stock in fresh soil.

MELONS DYING: *T. W. B.* The roots and stems are attacked by canker, for which there is no cure. Diseased plants should be destroyed on the garden fire, and the soil in which they have grown should be treated with lime.

MELON LEAVES: *D. M. L.* The plants are diseased by the fungus causing "leaf-rot." If the plants are not carrying fruit they may be

syringed with the Bordeaux mixture at half the usual strength; if fruit is present it will be best to use liver of sulphur. See also reply to *T. W. B.*

NAMES OF PLANTS: *J. W.* 1, *Kalmia latifolia*; 2, *Pieris floribunda*; 3, *Vaccinium corymbosum*; 4, *Escallonia macrantha*.—*A. T. H.* 1, *Rosa xanthina*; 2, Rose Mme. Hector Leuilliot; 3, Rose Soleil d'Angers; 4, *Ceanothus thyrsiflorus* var. *griseus*; 5, *Griselinia littoralis*; 6, *Ligustrum sinense*; 7, *Euphorbia Characias*.—*T. H. R.* Rose Lady Waterlow. —*W. R. P.* 1, *Veronica austriaca*; 2, *Cornilla emeroides*; 3, *C. Emerus*.—*J. A. P.* 1, *Tamarix gallica*; 2, *Atriplex Halimus*; 3, *Prunus Mahaleb*; 4, *Sedum praealtum*; 5, cannot name without flowers; 6, *Thalictrum aquilegifolium*.—*W. and B.* *Poa annua*.—*H. C. P.* *Sedum roseum* (*Rhodiola*).—*C. F. Smart.* Double *Pyrethrum* (*Chrysanthemum coccineum flore pleno*).—*Pat Blackbyrne.* Roses: 1, *Aglaia*; 2, *Auguste Barbier*; 3, *Thalia*; 4, not recognised; 5, *Blairi No. 2*. Shrub, *Cerasus Padus* (*Bird Cherry*).—*M. Wright.* 1, *Escallonia macrantha*; 2, *Pyraecantha coccinea*, sometimes called *Crataegus Pyraecantha*.—*F. Clarke.* *Brassica nigra*.—*Miss R.* *Pyrus terminalis*.—*E. P.* *Pernettya mucronata*.—*M. E. S.* *Sedum rupestre*, *Myosotis palustris*, *Geum rivale*, *Veronica gentianoides*.—*J. M. W.*—(1) Not recognised (*Rose*); (2) *Trachelospermum* (*Rhynchospermum*) *jasminoides*; (3) *Agatheae celestis*; (4) *Ceropegia Woodii*; (5) *Diplacus* (*Mimulus*) *glutinosus*.—*E. F.* *Oxalis Bowiei*.—*T. A.* (1) *Oncidium pubes*; (2) *Stelis ophioglossoides*; (3) *Miltonia candida*; (4) *Odontoglossum Lindleyanum*.—*B. C. B.* A fine form of *Salvia coccinea*.—*Mum.* *Lilium umbellatum erectum*.

ONIONS: *Ignorant.* Onions will root fully as deeply as Parsnips provided there is a sufficient depth of suitable soil; hence the value of deep cultivation.

PEACH FRUITS DROPPING: *G. G.* We have examined the fruits and find that the dropping is not due to a fungus disease; it is probable that you have afforded the roots too much moisture or the drainage of the border may be at fault, causing the soil to be water-logged. It would be advisable to overhaul the border next autumn when the trees are at rest, to ascertain if its condition is satisfactory.

PEACH LEAVES: *D. Hughes, F. W. C. and A. J. B.* The trouble is due to "Shot Hole" fungus—*Cercospora circumscissa*. The disease may be checked by spraying with liver of sulphur (potassium sulphide), and the work is best done when the leaves are only half grown. Therefore spray early next season, as the disease is almost sure to reappear. Liver of sulphur turns paint black; therefore, do not wet the painted woodwork of the house.

SWEET PEAS: *W. D.* The roots are attacked by a fungus—*Thielavia basicolor*—which is present in the soil. Sterilise the latter, either with fire heat or steam.

VINE LEAVES: *T. W. R.* Vine mildew is present. Spray the foliage with liver of sulphur, 1 oz. in 4 gallons of water. Spray early in the season next year before the mildew appears. — *E. C. W.* The injury to the vine foliage is not caused by a fungus disease or insect pests. It is a physical injury due to some external cause showing that the culture has been at fault. Most probably it is the result of a stagnant atmosphere. Ventilate the viney freely as early in the morning as can be done with safety.

WEED ON LAWN: *A. J.* The weed on your lawn is *Trifolium minus*. The best way to eradicate the Clover is to apply sulphate of ammonia, which will cause the grass to grow so luxuriously that it will in time crowd out the weeds.

ON JUDGING ROSES.

THE time of Rose shows and of judging Roses will soon be upon us, and it may be opportune to consider some of the problems connected with judging. The N.R.S. has laid down what are, no doubt, carefully considered rules for judging both exhibition and decorative Roses. The latter do and the former do not specify the qualities for which the judge should seek in making his award. Thus in judging decorative Roses the judges are directed to take into account brightness, form of flower, foliage, and arrangement, also diversity of the varieties and the setting up of the exhibit, and they are told that the relative sizes of different varieties is not to be taken into consideration. No similar guidance is given in the case of exhibition Roses. So many points are to be given for "high-class" blooms, and extra ones for "a very superior" bloom; but what is high-class and what superior are left to the discretion of the judge, without any attempt at definition. It is apparently only when the exhibits are of equal merit that the judges are to proceed to consider their general evenness, variety, arrangement, freshness, and setting up in the stands, otherwise they may be a law unto themselves. Notwithstanding this absence of definition it may be stated at once that as a rule the awards are well made.

There is, of course, no appeal from the judge's decision, but every judge well knows that his awards will be subjected to minute and thorough criticism, and the cases are very few in which the most careful attention is not paid to all the points which, in the view of the adjudicator, constitute merit in a Rose.

Occasionally, however, it happens that some appalling results are arrived at, not so much from any want of care in judging as from an unfortunate idea of what constitutes merit. By far the most common fault in judging Roses is the giving of an inordinate value to the quality of size in a flower. If only for the rather dreadful word "high-class" we could substitute "beauty," and for "a very superior bloom" we could read "a very perfectly formed and lovely Rose," much might be gained.

I remember when judging at a rather large country show, after we had finished our work, some of us looked round the show to see what the other judges had been doing. My eye was arrested by a flower erected above its fellows bearing the legend, "Best Rose in the Show." It was a vegetable of the Mildred Grant type. Long past any approach to beauty of form, if it ever possessed it, of a sad, bilious kind of yellowish mauve, very washy in hue, with somewhat limp and crinkled petals badly weather-beaten, and a mildewy piece of leaf, carelessly arranged, projecting beneath it, altogether a most undesirable looking object: but the size left nothing to be desired, and that I suppose was enough.

Parkinson tells us of the virtues of the Rose "that it serveth to cause suppleness of the body made into a syrup, or preserved with sugar," and again, "that it hath many physical uses, serving for many sorts of compositions, both cordial and cooling." For any or all of these purposes doubtless the Rose in question might have been invaluable; it would have afforded so much material; but as a thing of beauty it was woefully wanting. No doubt when judging classes containing very poor flowers it is often difficult to arrive at a satisfactory conclusion, but there was no difficulty of this kind in the case I have mentioned; the boxes in the classes from which the selection was made were numerous and contained some lovely flowers, though doubtless smaller than the one preferred.

Why is it that we give up to our Roses good garden ground that might grow admirable Lettuces, Cauliflowers, and Peas? Surely it is for the pleasure which we derive by contemplating the grace of form, pure fresh colouring, and the harmony of flower and foliage—in a word, the beauty and glorious perfume of the Rose. Surely in considering the Roses of our gardens mere size is a very secondary consideration. Proportion I admit at once, and there are many Roses which are not well proportioned, and do not give the real grace of form and beauty of which they are capable, except under high cultivation. Where this is the case size of the bloom may be at least tolerated, because it is necessary in these cases to ensure the

beauty we desire. Further, the exhibition Rose is set up in a box, and a flower that is below a certain size looks skimpy and out of place in that particular position. But need we go further?

So far as the general public is concerned, perhaps the question might be answered readily in the negative. No doubt they are attracted by, sometimes greatly interested in, the voluminous dimensions of the flowers they see in the winning boxes, specially those of the trade growers, hopeless though they may feel at times of ever attaining a like result in their own gardens. But when all is said, the attraction which draws most visitors to a show is the hope of finding something there which, when transplanted to their own gardens, will prove better than anything they possessed before. Which of them has not in his time fallen a victim to the charms of Bessie Brown, and given it a prominent and favourable position, only to find that as a garden Rose it is impossible? The perennial popularity of the tent for new seedling Roses and sports at the N.R.S. exhibitions bears eloquent testimony to the desire of the public to find something better than it at present possesses.

As regards exhibitors, whether professional or amateur, the question is not so easily answered. There can be little doubt that to some, perhaps to many exhibitors, the attraction of showing Roses in boxes, rather than in the decorative classes, consists in a feeling that they would like to know where they are. If they can produce bigger and more portly flowers than their rivals they like to feel that that is sufficient, and that they are reasonably certain of recognition. The feeling still exists that the exhibitors in the decorative classes are a hapless crew, with little to guide them in selecting their flowers, and largely at the mercy of the caprice of a judge who is equally without sure guidance, and must make his awards more or less haphazard. It follows that such exhibitors are to be pitied and the decorative classes avoided. This feeling is growing less as the decorative classes increase in popularity, and it may be the method of judging is becoming more settled. Quite recently, when some of the exhibitors of decorative Roses petitioned to be allowed to show in certain of their classes some varieties which seemed suitable for the purpose, but which had found their way into the exhibition lists, they were met with the gibe that they wanted to show ill-grown Roses, and that this ought not to be allowed.

Those who use such arguments would doubtless think it beside the mark to enquire whether a small, well-proportioned flower may not be more beautiful than one induced, perhaps by over-cultivation and excessive feeding, to assume the dimensions that would bring it up to exhibition standard. But is the enquiry quite fruitless? May not the over-fed and too corpulent child be as much an example of bad bringing up as one who has been ill nourished? Perhaps there may be some who would not admit an affirmative answer

to the last question, but in the long run it must become evident that the Rose exists and is cultivated for beauty alone, and that by its beauty it must stand or fall, and that kind of treatment that will bring it before the public in its greatest purity, freshness, and perfection of proportion must ultimately be the best form of cultivation.

I neither expect nor do I advocate any immediate change in the method of judging exhibition Roses. Such alteration as I desire will, I hope, come about gradually, and has, in fact, already begun. Judges, of course, have their idiosyncrasies. Of the judges whom I have met, one of the best colleagues I have had seemed to me, the first time I judged with him, so lost in admiration of all the flowers presented to his in-

yet which is usually a particularly well-formed flower, may the judge take into consideration the fact that the colour is to him displeasing, or must he ignore the colour altogether? Perhaps there are many who would take the latter view, but an ugly colour is certainly a want of merit in a Rose. Again, for a Rose to be "off colour" is universally admitted as a defect, but the degree to which it has to fall short of the judge's ideal of the particular variety for it to lose a point for this defect, varies with each judge, and with the same judge on different occasions.

It has often been suggested that the presence of perfume in a Rose should be considered in judging, and perhaps many of us would sympathise with the suggestion, and may be unconsciously biased to favour a flower with a

reduced to a gnarled shrub. It is described as forming the chief item in the arboreal vegetation of the Auckland Islands. It has the characteristic foliage of the Myrtle family, with leaves 2 to 3½ inches long, lanceolate or narrowly oval, pointed, shining green, and dotted with oil-glands beneath. It is, of course, evergreen, like the rest of the genus. The flowers (fig. 206) are produced at the extremities of the twigs, their chief feature being the bright crimson stamens, which are up to 1 inch in length, and very numerous in each flower. Kirk observes that New Zealand has few more magnificent sights to offer than a mountain slope covered with this species from its base to nearly 4,000 feet above sea-level, when the brilliant crimson flowers are lit up by the morning sun. In the milder parts of the

FIG. 206.—METROSIDEROS LUCIDA, WHICH HAS JUST FLOWERED AT NYMANS FOR THE FIRST TIME IN THIS COUNTRY. COLOUR OF FLOWERS CRIMSON.

spection that I wondered if he would ever come to a decision; but I found his choice none the worse for his obvious delight in the Roses, and, once arrived at a decision, he is seldom at a loss to give a good reason for it. To another the depth of petal in the flowers is a weighty consideration, so that one might almost expect he would wish to judge the flowers sideways, but he has an eye for a good flower for all that. A third will lay particular stress on the flowers being of a bright colour and typical of the variety, and will insist on taking any doubtful bloom for inspection outside the tent. And on the whole the tendency to reject large, ill-shaped, weather-beaten blooms is increasing. The question of colour is often one of considerable difficulty. If we take a Rose like Mrs. A. E. Coxhead, for instance, which is of a tolerably pleasing colour only at its very freshest, and to some scarcely even then,

delightful perfume. But the difficulties in giving serious effect to the suggestion are considerable. To begin with, noses vary much among judges as among ordinary mortals, and while many are competent to appreciate the full damask perfume of a Rose like Horace Vernet or Hugh Dickson, the more refined and delicate nuances of the varieties of the Teas and some of the H.T.'s are scarcely perceptible by a large number of individuals. *White Rose.*

METROSIDEROS LUCIDA.

This fine Myrtaceous tree is found in both the main islands of New Zealand, but is especially abundant in the South Island. There it forms an erect-branching tree, 30 to 60 feet high, although in exposed alpine situations it becomes

British Isles this tree may be grown out of doors, but over most of the country it will need winter protection. It succeeds in a loamy soil, and when given pot cultivation will be benefited, and flower better, if plunged in the open air for three or four of the summer months. Fig. 206 is reproduced from a photograph of specimens kindly sent us from Nymans, Crawley, the residence of L. Messel, Esq., and they are the first flowers of this species that come under our notice.

ORCHID NOTES AND CLEANINGS.

ORCHIDS AT THE WARREN HOUSE.

IN Mrs. Bischoffsheim's beautiful gardens at the Warren House, Stanmore, the collection of Orchids in the care of Mr. F. Jones is giving a good display of flowers. Goodly numbers of *Odontoglossums* are in bloom, chiefly of the best

type of *O. crispum*, arranged with red *Masdevallias*, *Epidendrum vitellinum majus*, and other brightly coloured species. *Disa grandiflora*, for which the gardens are famous, but which had gone back somewhat, is now again attaining its former vigour, and is well furnished with flower-spikes. In the intermediate houses is a good display of *Cattleyas*, *Laelias*, and *Laelio-Cattleyas*, among which some remarkably fine forms of L.-C. *Aphrodite*, L.-C. *Canhamiana*, and L.-C. *Martinetii* were specially good. Among the newer hybrids a pretty form of *Laelio-Cattleya Acis* (L. *tenebrosa* Walton Grange × C. *Mendelii gigantea*) has fine flowers, the white sepals and petals contrasting well with the deep claret-crimson lip. L.-C. *Gladiator* Warren House variety (L.-C. *callistoglossa ignescens* × C. *Mossiae splendens*) is certainly the best of its class, the flowers larger than those of the best C. *Mossiae*, the lip especially being remarkably developed. The sepals and petals are bright rose colour, the broad, flatly-displayed labellum ruby-crimson with gold lines from the base, and a well-defined, crimped white margin. A batch of *Phalaenopsis Rimestadiana* gives a good supply of large white flowers, and the Orchids of all classes are in excellent condition. The new seeding house promises well, and already there are numbers of hybrids in store pots and others still in the seed pots. A house of *Vanda coerulea* and a large number of good specimens of *Laelia anceps*, chiefly white varieties, give assurance of a good succession of bloom.

FRUIT PROSPECTS IN EASTERN COUNTIES.

Special Investigations by "SOUTHERN GROWER."

II.—SUFFOLK AND NORFOLK.

My inspection of fruit crops in Suffolk began on the farm of Messrs. Youngman and Sons, Charsfield Hall, one of whom kindly conveyed me in my journeys in his motor-car. Seventy acres of the farm are devoted to fruit. There had been a heavy hailstorm on the morning of my arrival, which had dented Apples, Pears, and Plums to some extent.

A great crop of Gooseberries, which are extensively grown, was in course of being gathered. Eleven acres are under Pears, some of which, on low ground, were damaged by a frost at Easter time. Where this was not the case great crops of *Emile d'Heyst*, *Fertility*, *Conference*, *Beacon*, and a local stewing variety named *Winter Orange* were seen.

About 25 acres are under Apples, the principal varieties being *Bramley's Seedling*, *Lane's Prince Albert*, *Worcester Pearmain*, *Warner's King*, *Royal Jubilee*, *Alington Pippin*, and *Beauty of Bath* among mature trees, while there are large pieces of *Early Victoria* and *Grenadier* not yet of bearing age.

Worcester Pearmain, which flourishes on the somewhat heavy soil of Charsfield, is extensively grown, the trees of mature age being twice as big as those seen at Wisbech, where the variety does not succeed well. The crop is one of the best, if not the best, of all, on this variety seen in the present year. The crop on *Bramley's Seedling* is a partial one, good in some parts of the orchards and light in others. *Lane's Prince Albert*, which, like *Bramley*, bore a great crop last year, is not fruiting well this season. This has been a common result in all the districts traversed. *Beauty of Bath* is bearing a moderate crop. A good deal of damage to Apples has been done by a *Capsid bug*, a pest to which insufficient attention has been devoted. It marks the fruit by eating shallow furrows in it and otherwise scarring it, while it also injures the foliage.

Plums cover 13 acres, and are bearing the best crop seen in the course of our tour, particularly *Victoria*, *Czar*, *Transparent Gage*, *Mallard*

(another dessert variety), and *Early Rivers*. *Curlew* is not fruiting well this year, and *Wyedale* is not in healthy condition.

Brown rot has been prevalent among Apples and Plums, especially on *Wyedale* Plums. The aphid also has been troublesome among Plums, and to a less extent among Apples.

Black Currants, which are largely grown, are bearing a crop from fair to good, according to the variety. Several varieties of this fruit are grown, including a new one, *Edina*, which has the advantage of late ripening.

Raspberries and Strawberries are not grown for market now. The former were grown largely at one time, but were given up, partly on account of the distance of the orchards from markets, and partly because the soil did not suit them well.

HOLLESLEY BAY.

A motor drive of about 14 miles brought us to the *Hollesley Bay Labour Colony*, an estate of 1,300 acres, of which 200 acres are under fruit, the greater part of which has been planted in recent

is fair to good, and on the whole the best seen in our tour.

Early Rivers, *Czar*, *Victoria*, and *Monarch* are the principal Plums, and these are bearing fair to good crops for the season.

Royal Sovereign and *Sir Joseph Paxton* Strawberries are well fruited, and Raspberries were promising.

An extensive area is under Gooseberries, the crop of which was a good one. The Black Currants are *Boskoop Giant* and *Baldwin*, and there is a good crop of the former and a fair one of the latter. The *Red Currant* crop is a short one.

Six large glasshouses in one block are devoted to Tomatoes, Cucumbers, and Strawberries, and there are two or three others which were passed at a distance.

A plan is in contemplation for supplying the whole of these excellent orchards with spraying stuff by means of underground mains and branch pipes.

On arriving at the outskirts of Norwich on the

FIG. 207.—POLYSTICHUM MUNITUM UNDULATUM.
R.H.S. Award of Merit on June 16, 1914 (see p. 442).

years under the direction of Mr. Barton, farm and orchard manager, who kindly showed us round. About 100 acres are under Apples, 30 acres under Plums, 30 acres of Raspberries among trees, 30 acres of Strawberries, and considerable areas of Gooseberries and Black and Red Currants.

The principal Apples grown are *Cox's Orange Pippin*, *Quarrenden*, *Early Victoria*, *Bramley's Seedling*, *Newton Wonder*, *Lane's Prince Albert*, *Lord Derby*, *Alington Pippin*, and *Beauty of Bath*. A few rows of *Charles Ross*, of which Mr. Barton thinks highly, were also noticed. Many of the Apples are too young to bear much at present, but the crops on the older trees are among the best which we saw in the course of our tour. *Cox's Orange Pippin* flourishes on the light soil of *Hollesley*, and is bearing a full crop for the age of the trees. There is a fair crop on young *Bramleys* and a good one on mature trees, while *Newton Wonder*, *Worcester Pearmain*, *Lord Derby*, *Charles Ross*, and *Beauty of Bath* are fruiting well. The crop of *Lane's Prince Albert*

following day, a detour was made to *Eaton*, as it was my desire to visit the nursery owned by Mr. H. Morse, from whom I had had many excellent fruit trees. Here, besides a great number of well-grown maiden and two-year-old Apples and Plums, with thousands of *Roses*, we saw several varieties of Apples and Plums which Mr. Morse brought over from Australia and New Zealand when visiting those Dominions a year or two ago. If it will succeed in this climate, an Australian Plum, unhappily named *Tragedy*, will be a great acquisition, as it is said to be a week earlier than *Early Rivers*, and as big as *Black Diamond*. The best Apple from New Zealand, Mr. Morse thinks, is *Winter Pearmain*, a dessert variety which keeps till May. *New Zealand Cool* is a fine dessert Pear and a late keeper. Several other varieties of fruit from Australia, New Zealand, and South America were seen, but time is needed to test them in this country. Two Apples, of English raising, not yet commonly grown, were pointed out as deserving trial. These are *Crimson Bramley*, raised by Mr. Merryweather, of Southwell, Notts, and *Red*

Victoria, which, I believe, was raised at Evesham.

WESTWICK.

Our principal object in travelling to Norwich was to see the orchards of Colonel Petre, of Westwick Hall, about 13 miles from the city. A high authority of great experience had informed me that the finest plantations of Black Currants he had ever seen were at this place. After seeing Colonel Petre, who takes a great interest in his remarkably fine orchards, we were shown round by his manager, Mr. Davison, under whose directions almost the entire 75 acres of fruit have been planted and cultivated.

The soil is light loam of considerable depth over sand. It is destitute of lime, and yet Apples, as well as Black Currants, make splendid growth in it. Some trees of Branley's Seedling, Newton Wonder, and Alington Pippin, planted 13 years ago, are among the largest for their age that I have ever seen, although they are on the Paradise stock. These particular trees bore great crops last year, and are taking a rest, but younger Alingtons are bearing heavily. Quite as remarkable for the variety is the growth of Lane's Prince Albert on Paradise, planted seven years ago. The trees are 12 feet apart, but are already about to interlock. As nearly everywhere, this variety is very short of fruit this season. Some fine crops of Apples were noticed on Worcester Pearmain, James Grieve, Lord Derby, and Newton Wonder. Neither Cox's Orange Pippin nor Warner's King can be grown to advantage at Westwick, as both canker badly.

Plums do not flourish in the district, and have not been tried at Westwick to any considerable extent. There are 12 acres of Cherries, five years from the planting, which are fruiting well.

There are 24 acres of Black Currants in bearing among Apple trees, and 10 acres of young bushes. They are mainly of a variety raised from a very old stock grown in the garden of the mansion, named Westwick Champion, and a remarkably fine variety it is. Some bushes of Boskoop Giant and Baldwins are also grown, and they flourish splendidly. Mr. Davison estimates an average crop from mature bushes at 21 lbs. per bush, and in a fully bearing year, he said, he got 50 tons from 24 acres. He reckons this year's crop less than a fourth of a full one, but to his visitors it appeared a fair crop. Some bushes 15 years old are perfect giants, 6 feet high, and very widely spread.

Reversion among Black Currants is troublesome at Westwick, as it appears to be everywhere. Mainly for this reason Mr. Davison has raised under glass eight different crosses, the seedlings from which are planted on six acres. The parent stocks are Westfield Champion, Boskoop Giant, Baldwin, and Victoria, crossed both ways. For example, the pollen of Champion was applied to Victoria, and *vice versa*. The results of this extensive experiment will be very interesting.

There are nine acres of Raspberries, mainly of a local Kent stock known as Prosperous. The canes are short but very prolific.

One main and two branch pipes underground, supplemented by light steel pipes with flexible joints and some lengths of hose, supply spray wash, driven by a 7 h.p. oil engine, to the whole of the 75 acres of fruit. The plant cost £400.

Our intention was to visit, if allowed to do so, another fruit farm about seven miles from Westwick, that of Mr. Cubitt, of Honing, but after walking about Westwick in a steady downpour of rain for over two hours we were not in a condition for extending our journey beyond a place 18 miles from Norwich, our sleeping place for the night, and we were due at Wisbech on the following day. Moreover, we did not know whether we should find the owner at home, or whether a visit from strangers so late in the day would be welcome. We were informed, however, that the orchards are carried on very much on the same lines as those of Westwick, and are

of about the same dimensions. The cropping is similar, about as many acres of Black Currants being grown, as well as Apples, but no Plums. One different feature at Honing, however, is the growing of 10 acres of Catillac Pears.

CONCLUDING REMARKS.

Nothing struck my companion and myself more forcibly in the course of our tour than the generality of certain features of the season in connection with varieties of fruit cropping, well or otherwise. Frost and drought had marred the fruit prospects in all the orchards visited; but the fact that early Apples are very much more productive this season than late ones seems to indicate that drought did much more harm than frost to that fruit. Drought had not become severe when early Apples were setting their blossom, but had become so when the late varieties had their turn. The very common failure of Victoria Plums is accounted for by the lack of leafage upon that variety when the first May frost occurred. Less easily explicable is the general immunity of Pears from frost injury, and the equally common escape of Gooseberries and Currants. Remarkable, also, is the very considerable recovery of Strawberries from frost damage in most places. Drought was more damaging than frost, I think, to this crop, as it threatens at the time of writing to be to Raspberries also.

PREVALENCE OF GOOSEBERRY MILDEW.

A lamentable observation is that we found American Gooseberry mildew more or less extensively prevalent in every plantation that we saw. Growers are in despair about it, as no one can suggest a cure. That the continuance of tipping would ruin the bushes is certain. Some that we saw were dense masses of young shoots in consequence of tipping. The disease is almost universal in market plantations.

From what has been written in my two reports it will be seen that the fruit prospects are much better in the Suffolk and Norfolk orchards visited than in those of Cambridgeshire. On the whole, the impressions conveyed from my observations during the tour are that early Apples are a good crop, late varieties a very light one. Plums much below average, Gooseberries well up to the mark, except for mildew. Both Black and Red Currants are short, Raspberry prospects fair to good where not deteriorated by drought, and Strawberries fair to good. *A Southern Grower.*

BIRMINGHAM PUBLIC PARKS AND OPEN SPACES.

Those to whom the woods and pastures of the beautiful county of Warwick are dear have viewed with dismay the growth of the City of Birmingham, which has flung out greedy arms and swallowed up many hundreds of acres of green fields. The city authorities, however, have not been unmindful of the need for open spaces and fresh air, which are increasingly needed as the country retreats further and further from the heart of the town. They have provided a number of parks and recreation grounds (eighty in all) where children and adults alike can find rest and opportunities for healthful games. In several of the parks camping out is permitted, open-air bathing can be indulged in, and provision is made for boating and fishing. The largest of the open spaces is the Castle Bromwich Playing Fields, 250 acres in extent, situated to the north-east of the city. Many of the smaller spaces are ancient churchyards, which have been converted into very pleasant resting spots, and at King's Norton, the old "village green" has been preserved, instead of remaining, as in so many cases, nothing but a name. One of the best parks from the garden point of view is Canon Hill, but gardening is well carried out at most of them. Mr. W. H. MORTER, the chief officer, sends us a map and particulars of the parks in an attractive pamphlet, which is issued to the public at the price of one penny.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. COOKSON, Oakwood, Wylam-on-Tyne.

SEEDLING ORCHIDS.—Seedlings of Cattleya, Laelia and allied genera raised this year have made their first roots, and should be transferred to small pots, or several may be placed together in 3 or 4 inch pots or pans. As I have previously stated, the plants are best grown in small pots, but where space is limited the other system should be adopted. The compost should be of a lasting nature, and chopped fine, according to the sizes of the pots used. It may consist of equal portions of peat fibre, AI fibre, and finely-chopped Sphagnum-moss, intermixed with sufficient silver sand to render the materials porous. The pots should be thoroughly clean, and may be filled to about two-thirds their depth with drainage materials. Press the soil moderately firm, and arrange it to form a slight mound about the stems, making it trim with the shears. It is an advantage to do the work of potting in showery weather. The plants may be sprayed overhead freely two or three times a day in fine weather, the object being to keep the atmosphere humid. In hot, dry weather the house may be damped the last thing at night, unless other means exist for keeping the atmosphere moist during times when fire-heat is employed. Seedlings in a more advanced stage may require increased root room, and the work of repotting may be done now if the old compost is in a good condition. The roots should not be disturbed more than is occasioned by turning them out of their pots and transferring to larger receptacles. The compost should be graded according to the size of the pots, and the durability of the compost is of great importance. Recently potted plants should be sprayed overhead daily, and afforded every encouragement to remain plump and healthy.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

HARDY PERENNIALS.—It is the common practice to plant hardy herbaceous flowers in mixed borders, but here they are massed in bold groups, which is the finest way of displaying them. We have a garden of hardy herbaceous plants, and each subject is planted in a group by itself. The size of each bed is arranged in accordance with the habit and general characteristics of the species employed, and there is a sufficient choice of subjects to give plenty of variety. Usually in the herbaceous border the different subjects are arranged so that the taller ones are at the back, grading to the dwarfier kinds in the front, giving a formal appearance. Our system is to choose for the more prominent positions those that flower longest and best, whilst the height of the different beds is varied. The blending of the colours of the various plants needs consideration, and with a little forethought it is an easy matter to make pleasing floral pictures, as there is an endless variety of suitable subjects.

MICHAELMAS DAISIES.—The growths of perennial Asters need to be thinned, and all weakly shoots should be pulled out by the roots; the main growths of such varieties as Climax and other strong growers should be afforded a space of at least 1 foot, allowing them to grow a little closer in the case of less robust sorts. It will benefit the plants to feed the roots with liquid manure, soot or concentrated fertiliser. As the growths advance they will need supports of some kind, and short, stout, twiggy Hazel sticks are suitable for the purpose. The stick should be arranged so that the clump is wider at the top than at the bottom. In these gardens Michaelmas Daisies are planted in the turf, where they are greatly admired during the late summer and autumn, and they furnish excellent

material for cut blooms. The variety *Tradescantii* flowers in late November, thus giving a succession of bloom until almost the winter. The feathery inflorescences are very graceful, and the variety is to be recommended for planting.

THE FORMAL GARDEN.—It is far better to retain the moisture in the soil by applying mulches than to be constantly watering the roots, for frequent waterings may not only cause the plants to become chilled but have a tendency to make the soil sour as well as to wash much of its goodness below the roots of the plants. Important details to be observed just now in the formal garden include the pinching back of extra strong growths, pegging some of the shoots to the soil and placing small, twiggy sticks as a support to the plant. Let all this work be done before wind and rain have beaten down and injured the growths.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

SPINACH.—Spinach is a particularly troublesome crop at this season. In very dry weather the seed is best sown as follows:—Draw the drills—which need be only a few inches apart—water the soil through a fine rose, sow the seed, cover it with soil, and water the surface of the bed through a coarse rose can, or by means of the garden hose. Afterwards place mats over the seed-bed until the seedlings appear. In hot weather the plants run to flower so soon that it is advisable to make the sowing thicker than at other times, moreover the leaves in summer grow so small that it is a waste of ground to sow thinly. If a constant supply of this vegetable is required frequent sowings must be made from now onwards, even when the crop is supplemented with New Zealand Spinach.

ENDIVE.—Seedlings of this crop should be transplanted into rows, and a fresh batch of seeds sown to raise plants to follow those of the previous sowing.

PEAS.—It is not safe to delay making the latest sowing of this vegetable. If the ground is unduly dry the trenches, after being made firm and then stirred lightly to produce a good rooting medium, should be soaked with water, and the soil used for covering them also well moistened. As soon as the soil is in a condition for working again sow the seeds and cover them to a depth of 2 inches, placing on the surface an inch of pulverised soil to act as a dry mulch. Be on the watch against infestations of thrips on the earlier sowings, and should the pest be detected spray the plants with nicotine. Soapsuds mixed with petroleum is a cheap and fairly reliable insecticide for the destruction of thrips and other insect pests where a large quantity of specific is required.

CUCUMBERS.—Cucumbers can be grown without fire-heat now, but the roots will need less moisture than the earlier plants, seeing that fire-heat is dispensed with. The shoots may be pinched at each joint, and their number should be reduced where there are so many that there is not space for all the foliage to expand. Thin the fruits where there is an over-crop, and cut the Cucumbers as soon as they are large enough for the table, for if allowed to remain longer they will deteriorate, and, moreover, have the effect of exhausting the energies of the plants. Dress the surface with a mixture of vine manure and loam. Spare no means to keep down infestation of aphides, thrips, and red spider, and admit sufficient fresh air through the ventilators to keep the atmosphere sweet.

CELERY.—The planting of Celery for the main crop should be no longer delayed. If the soil is dry, soak the trenches a few hours previous to planting, and then spread a thin layer of dry soil over the moist surface. If the earlier plants show signs of exhaustion from drought, let sufficient water be afforded the roots to keep the crop growing freely until rain falls. It must be remembered that the hardier the conditions under which Celery is grown the better will the plants withstand the effects of wet and frost when they are full grown. There is plenty of

time yet for growth to develop, as Celery grows very rapidly as soon as the nights begin to lengthen.

ASPARAGUS.—Thin seedling Asparagus to 6 or 9 inches apart, in order to secure strong roots for transplanting next season. Beds that were planted this spring will need attention, as young Asparagus grows fast and the shoots require staking and tying to prevent them being damaged by winds. Established beds must be kept clear of weeds, and the surface well stirred; enrich the soil with nitrogenous manure, for when growth is rapid the shoots mature early. In exposed gardens it is necessary to support the shoots to stakes.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

STATICE PROFUSA.—Strong plants may be permitted to flower now, and they will be benefited by applications of weak liquid manure, supplemented on alternate occasions by a little Clay's fertiliser. The shoots of this Statice become very heavy in time, and are liable to become split at the junction with the stems: therefore it is necessary to support them to stakes. The plants will succeed in a greenhouse temperature at this season. They are very valuable as decorative subjects, lasting for a long time in bloom. The flowers are useful for winter decoration; spikes required for this purpose should be cut just as the flowers expand and suspended in an airy house to dry.

GREENHOUSE CLIMBERS.—Species of *Cestrum* and *Streptosolen Jamesonii* may be pruned, removing weak shoots and any that have flowered. Do not neglect the plants now that their beauty is over, for next season's flowering will depend upon the treatment afforded now. Important cultural details are keeping the shoots trained to the roof-rafters and pillars and syringing the foliage with clean water to keep down attacks of aphids. The roots also must be watered freely during hot weather. The *Heliotrope* is often grown as a pillar plant in greenhouses, and specimens planted out in borders flower profusely. If the untidy shoots are cut hard back now the plants will make fresh growth that will flower well in September. The old wood of *Swainsonias* should also be cut out to afford space for training in the young growths, which should be secured lightly to the pillars on which they are grown. Other plants that require their growth thinned and trained include *Passifloras*, *Tecomas*, *Cobaea scandens*, *Tasconias*, and *Lapagerias*. All these plants should be freely syringed on bright days.

CODIAEUMS AND DRACAENAS.—The tops of tall, spindly specimens of these plants may be taken off and inserted singly in thumb pots, to be rooted in a brisk bottom heat. Stems of old *Dracaenas* may be cut into pieces about one or two inches long and inserted in sandy soil for rooting. Plunge the cutting-pans in a bottom heat of 85°. When shoots and roots have developed the plants may be inserted singly in thumb pots. Later they should be grown on a shelf near to the roof-glass and syringed freely.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

VINES.—Give close attention to the airing of the houses by the top ventilators, opening the latter early in the morning and gradually increasing the amount of air as the sun gains strength. Front ventilation must be used with caution, and the ventilators not opened to any great extent excepting on calm, hot days. Guard against infestations of red spider, especially in houses where little moisture is used because of the bunches ripening. Remove all lateral growths that are not required, and attend to the watering of the borders. Afford a liberal treatment to vines growing in pots, whether intended for fruiting this year or next. Encourage young vines planted out this season to root freely and

develop plenty of top-growth. Admit an abundance of fresh air in favourable weather, as this will favour the gradual ripening of the canes. Dispense with shading, if this can be done with safety.

MELONS.—Where successive cropping is not practised the present is a suitable time to make a sowing for autumn fruiting. Melons planted at this time of the year should be afforded a greater depth of soil than those set earlier, and it should be made firmer in planting. Melon plants in all stages should be mulched with Coconut fibre, leaf-mould, or half-decayed manure, to obviate frequent waterings. Water the roots thoroughly when moisture is required, for many crops of Melons are ruined through drought at the roots. Attacks of mildew are often the result of allowing the soil to become dry. Admit an abundance of air to plants bearing fruits in process of ripening, and see that the soil is neither excessively moist nor quite dry. Plants intended to furnish fruits for a succession should be stopped at one joint beyond the fruit. When a suitable crop has set on each plant, remove all other fruits that set. Feed the roots from time to time, and keep the foliage clean and free from insect pests.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOLE, Eastwell Park, Kent.

RED AND WHITE CURRANTS.—The bushes have practically completed their growth, and may be summer-pruned with a view to the fruits and plants receiving the full benefit of sunlight and air. Stop the side-growths at the fourth leaf, but do not shorten the leaders for another week or two. Both Red and White Currants do well when grown as cordons on walls, and such plants produce choice fruits suitable for dessert purposes. If some are planted on either a north or east wall the season when Currants are available will be prolonged until late in the autumn. During times of drought these small fruits require attention in watering, and especially when they are grown in light soils, for an insufficiency of moisture at the roots has the effect of causing the fruit to shrivel. The shoots of cordon trees should be cut back as in the case of the bush specimens. In gardens where space is limited Currants may be grown against a fence or trellis work; another plan is to grow them as standards, such plants being attractive in appearance, and the fruits are easily protected from birds. Bushes infested with aphids should be cleansed of the pest before the fruit commences to colour, or the berries may be spoiled. Let the soil between the bushes be well hoed, and apply a fresh layer of manure as a mulch, if this is necessary, before placing the nets in position to protect the fruit from birds.

BLACK CURRANTS.—This crop also should be protected by netting, which should be placed in position at once. In the case of the Black Currant it is not necessary to thin the shoots; any pruning is best done after the fruit is gathered, when all old wood that has fruited and any other that can be spared should be cut clean away, the object being to furnish the plant with young shoots from the base. If the soil is dry give the roots a soaking of clear water, and afterwards feed them with concentrated fertiliser or liquid manure, finally applying a mulch of short litter.

GOOSEBERRIES.—Stop Gooseberry growths of the current year, as in the case of Red and White Currants. The fruits having been thinned freely whilst they were still green are growing rapidly, and attention must be paid to watering the roots whenever this is necessary. In order to retain the moisture in the soil, hoe the surface and apply a mulch over the roots. If the bushes are infested with insect pests take measures to destroy the latter before the fruits commence to ripen, as it is not advisable to apply washes when the fruit is almost ready to be gathered. For this reason it is also advisable to wash the bushes with clear water after applying insecticides; if the water is applied with force it will do good in many ways.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — Our correspondents would oblige by delaying in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPOINTMENTS.

- SATURDAY, JUNE 27—
British Gardeners' Assoc. visit to Kew. Windsor, Eton and District Rose and Hort. Soc. Sh.
- TUESDAY, JUNE 30—
Roy. Hort. Soc. Summer Sh., Holland House, Kensington (3 days). Hort. Club Dinner and Lecture, 7 p.m. Roy. Agricultural Soc. Ex. at Shrewsbury (4 days).
- WEDNESDAY, JULY 1—
Reigate Fl. Sh. Colchester Fl. Sh. Southampton Rose Sh.
- THURSDAY, JULY 2—
Dover Hort. Soc. Sh.
- FRIDAY, JULY 3—
Dundee Hort. Assoc. meet.
- SATURDAY, JULY 4—
Soc. Française d'Horticulture de Londres meet. Sutton Rose Sh.
- TUESDAY, JULY 7—
Nat. Rose Soc. Sh. at Botanic Gardens, Regent's Park. Wolverhampton Floral Fête (3 days). Scottish Hort. Assoc. meet.
- WEDNESDAY, JULY 8—
Elstres Hort. Soc. Sh. West Surrey Hort. Soc. Sh. at Camberley. Weybridge Fl. Sh.
- THURSDAY, JULY 9—
Finchley Hort. Sh. Potters Bar and Dist Sh.
- FRIDAY, JULY 10—
Burnt St. Edmunds Sweet Pea and Rose Sh.
- TUESDAY, JULY 14—
Roy. Hort. Soc. Coms. meet. (Lecture at 3 p.m. on "The Cooking of Leaf Vegetables.") Saltaire and District Sh. (2 days). Arbori. Ex. at Hawick (4 days). Gloucestershire Rose and Sweet Pea Sh.
- WEDNESDAY, JULY 15—
Formby Hort. Soc. Sh. Nottingham Hort. Soc. Sh. (2 days). Llandudno and District Hort. Soc. Sh.
- THURSDAY, JULY 16—
Nat. Sweet Pea Soc. Sh. at R.H.S. Hall. Nat. Rose Soc. Sh. in Sydney Gdns., Bath. Birmingham Floral Fête (3 days). Manchester and North of England Orchid Soc. meet.
- FRIDAY, JULY 19—
Nat. Carnation and Picotee Soc. Sh., R.H.S. Hall.
- TUESDAY, JULY 21—
Southampton Hort. Soc. Sh. (2 days).

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 61.7°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, June 24 (6 p.m.): Max. 71°; Min. 48°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, June 25 (10 a.m.): Bar, 29.7; Temp. 70°. Weather—Bright Sunshine.

PROVINCES, Wednesday, June 24: Max. 71°, Bournemouth; Min. 45°, Dover.

SALES FOR THE ENSUING WEEK.

WEDNESDAY, THURSDAY, AND FRIDAY—

Three days' unreserved clearance sale of the whole of the Stove and Greenhouse Plants at the Royal Exotic Nursery, King's Road, Chelsea, by order of Messrs. J. Veitch and Sons, Ltd., by Protheroe and Morris, at 12

Bacterised Peat.

The results of Professor Bottomley's investigations of the causes of the remarkable stimulative action exercised on plant growth by bacterised peat were communicated by the author to the Royal Society on Thursday, June 18.

Professor Bottomley has obtained evidence which leads him to suggest that the stimulating effect is due to the formation or liberation during the preparation of bacterised peat of minute quantities of substances which play with respect to plant growth a part similar to that played by the so-called accessory food substances in the nutrition of animals. By appropriate methods he has isolated from bacterised peat substances which, when added to the medium in which plants are growing, increase the rate of plant-growth in a remarkable manner. He finds, moreover, that these accessory food substances are essential for the continued life of seedlings. If, for example, seedlings are grown in pure distilled water, to which are added all the mineral substances which ordinarily suffice to bring about active growth, he finds that though the seedlings at first gain weight they subsequently lose weight and die; whereas if in addition to the complete mineral "food" there be added an extract containing a small amount of the accessory food substances, the growth of the seedlings is considerable and continuous.

Plant physiologists will require overwhelming evidence before they will be prepared to accept this conclusion; for many of them have used distilled water and pure chemicals for the purpose of water cultures and have found that plants may be raised from seed to seeding stage although the water in which they grow contains nothing but mineral salts. This objection, however, is not fatal to Professor Bottomley's hypothesis, for it is quite in accordance with physiological experience that an organism may be able, given appropriate conditions, to manufacture its own "growth stimulators." Indeed, the fact that the accessory food substances necessary for the nutrition of animals are derived from plants makes it highly probable, if not absolutely certain, that these substances are manufactured by the plant. Hence it is but natural to suppose that the accessory food substances, formed by the plant, play in the economy of the latter the same rôle as that which they play in the animal that feeds upon them.

The fact that seedlings may be grown in ordinary tap water, to which the necessary mineral substances have been added, is interpreted by Professor Bottomley to mean that the tap water, owing to its contact with soil, contains traces of these growth-stimulators. Professor Bottomley's researches open up a new and an extraordinarily interesting chapter in plant-nutrition, and if, as the result of further inquiry, his conclusions are established he will have laid both botanical science and horticultural practice under a deep debt of gratitude. It is at present premature to express a definite opinion on the sub-

ject of accessory plant-food substances, but it may be said with confidence that Professor Bottomley has made out a prima facie case for the existence of such substances. We have on the one hand the argument from analogy: the existence of accessory animal-food substances having apparently been demonstrated to the satisfaction of physiologists; and on the other hand we have the striking evidence already published in these columns (*Gardeners' Chronicle*, March 21, 1914, p. 204) that bacterised peat actually exercises a definite stimulatory influence on plant growth. At the present stage of the inquiry the best criticism is constructive, and should consist not in arguing the pros and cons but in repeating and extending the experiments begun by Professor Bottomley. An aspect of the subject of particular interest to horticulturists is this—that gardeners as a class have resolutely refused to believe that artificials are the equals of natural manures. If Professor Bottomley's theories are established that prejudice will receive a real measure of justification; although let us hasten to add even so the justification will be by no means complete, for the poverty of a soil in nitrogen, phosphorus, and potassium compounds cannot be compensated by the presence of accessory food bodies.

Coloured Plate.—*Begonia "Eclipse,"* the subject of the Supplementary Illustration, belongs to the winter-flowering section, which originated through crosses between the fibrous-rooted *B. socotrana* and varieties of the tuberous-rooted section. The variety *Eclipse* received the R.H.S. Award of Merit on November 19, 1912, when shown by the raisers, Messrs. CLIBRANS, Altrincham, who on the same occasion received Awards for three other varieties.

HORTICULTURAL CLUB.—A house dinner of the Horticultural Club will take place on Tuesday next, the 30th inst., at the Hotel Windsor, Victoria Street, Westminster, at 7 p.m., when Mr. CHAS. E. PEARSON will deliver an address on "Sports." The following new members were elected at the last meeting:—Messrs. W. L. BRADBURY, A. McBEAN, JAMES KELWAY, and A. D. WEBSTER.

A BOTANIST DECORATED.—On the occasion of his retirement from the service of the Egyptian Government Mr. W. LAWRENCE BALLS has received from the KHEDEIVE the Order of the Medjidieh (Third Class). Mr. BALLS has rendered conspicuous services to Egyptian agriculture, and his work on the Cotton plant in Egypt, which was reviewed in these columns on November 9, 1912, demonstrates the devotion and skill which he has displayed during the years in which he has held the post of botanist to the Egyptian Government.

HOLLAND HOUSE SHOW.—The Summer Show of the Royal Horticultural Society will be held at Holland House, Kensington, by permission of MARY Countess of ILCHESTER, on Tuesday, Wednesday, and Thursday next, June 30, July 1, 2. The plan of the show will follow, in the main, that of former years. There will be several tents for the accommodation of groups under canvas, and certain exhibits will be staged in the open. Horticultural sundries will be extensively displayed, both in the open and in a special tent. We learn that the number of entries has exceeded the space available, but curtailment in this respect always raises the quality, and it is expected that the show will be equal in every respect to those of former

WINTER-FLOWERING BEGONIA, ECLIPSE

years. Last year's exhibition was a record one, and it only needs fine weather to make this year's show the finest of the series.

NATIONAL ROSE SOCIETY'S SHOW.—The National Rose Society's Thirty-Seventh Annual Exhibition will be held on Friday, July 4, in the Botanic Gardens, Regent's Park. The schedule embraces 111 classes, and, judging by the long list of exhibitors who have entered for competition, the show should prove equal to the best held by this successful society.

DATES OF THE FLOWER SHOWS.—A useful list of flower shows for 1914 has been sent us by Messrs. AUSTIN AND MCASLAN, Glasgow, who ask us to announce that it is distributed gratis.

GLOUCESTERSHIRE ROSE AND SWEET PEA SHOW.—We are informed by the Secretary that the date of this show has been altered from Friday, July 3, to Tuesday, July 14.

THE MANURIAL VALUE OF BACTERISED PEAT.—Among the numerous trials which are being made during the present season on the manurial value of bacterised peat those in progress at Messrs. Sutton and Sons' trial grounds at Reading promise to be of particular interest. The season is as yet too early for the results on the various crops to be forthcoming; but we hope to publish a full account of the trials in a few weeks' time.

AMATEURS AND THE EXHIBITIONS.—A correspondent writes to us on the question of amateurs' exhibits at the shows, deploring the fact that they are constantly becoming less numerous and tracing their decline to want of sympathetic recognition on the part of the show authorities. In former days the arrangements at the Royal Horticultural Shows were more on the lines of the provincial shows of to-day—namely, certain competitive classes were arranged, and these classes were divided into sections. Some were reserved for amateurs, some for nurserymen, and others were arranged in which both nurserymen and amateurs could compete. This system was allowed to fall into disuse, and Fellows were left to send groups of any kind that they were able to show, it being thought that such groups were more easy of artistic arrangement than anything that could be shown in specialised classes. In these circumstances the exhibits are judged relatively, and the value of the medal decided on a general basis. The result is that the amateurs compete with nurserymen, although they cannot be expected to have the resources of a nurseryman at their command. It is only the few amateurs who have the most extensive collections who can hold their own on such terms, and the smaller amateurs are discouraged. Gradually, therefore, the shows have come to depend less on amateur growers and more upon members of the trade. This is noticeable not only at the fortnightly exhibitions in Vincent Square, but also at the Chelsea and Holland House Shows. In the reports published in these columns there are just a few names of amateurs that occur again and again, but there is seldom a new name. This is to be regretted, because it is from the ranks of the smaller amateurs that those who eventually specialise and cultivate large collections are recruited. Take, for instance, a nurseryman's exhibit of Sweet Peas or Orchids at any of the R.H.S. shows. It is staged on the same day as another collection of Sweet Peas or Orchids from an amateur grower. When they are judged for medal awards no allowance is made for the fact that the one exhibit is staged by an amateur, who cannot expect to obtain anything for his exhibit but the honour of an award, and the other by a nurseryman, who expects to get his compensation in various ways. We know perfectly well that nurserymen dislike very much to have to compete with amateurs, and that they would welcome any provision for ensuring that amateurs'

exhibits should be judged apart from the trade element, and the awards, as compared with those given the trade, made more liberal. We are convinced that the Council of the R.H.S. would do well to adopt measures calculated to increase the number of amateur exhibits at the fortnightly meetings and summer shows.

GIFT TO THE CHURCH ARMY'S CITY GARDENS.—An Irish lady has given about 150 seed-raising "cloches" for the use of the free-plot-holders of the Church Army "City Gardens," where vegetables and flowers are grown by poor men on waste building sites lent to and converted by the Society.

DR. LOUIS TRABUT.—The *Journal of Agriculture* of the University of California contains an appreciative article by Mr. Paul Popenoe on the work which Dr. Louis Trabut, the distinguished botanist, has done for the colonists of Algeria. Director of the Botanical Service of the country, and professor in the medical department of the University of Algiers, Dr. Trabut possesses an unrivalled knowledge of the flora of the Mediterranean region, and knows how to put that knowledge at the disposal of the cultivators of the great African dependency of France. Interested specially in economic botany, Dr. Trabut has made his journeys in the hinterland of Algeria the occasion of not a few notable discoveries. Among these Mr. Popenoe mentions the finding of a spineless Artichoke. Whilst botanising in the neighbourhood of Constantine, where the Artichoke exists in a wild, spiny state, Dr. Trabut noted a large fenced enclosure around the source of the municipal water supply. Here, if anywhere, he argued, should a spineless plant find safety, and there he found it. Introduced into cultivation, this wild Artichoke is said to have proved of considerable value owing to its drought-resistance. Applying similar reasoning, Dr. Trabut has discovered in sheltered situations many races of forage plants superior to those which occur in the open, where, if they are to live at all, they must be able to resist both drought and animals. Of these plants, some, such as the Tangier Pea, Scarlet Vetch, and Sudan Grass, have been introduced into California. Conversely, the California Navel Orange and the Grape Fruit have been introduced by Dr. Trabut from America to Algiers. Last, but not least, Mr. Popenoe mentions that the long-neglected Botanic Garden of Algiers has been placed under the charge of Dr. Trabut, and may therefore aspire once again to rival the great gardens of the world.

LAVINGTON PARK.—At the time Mr. THOMAS DOWN wrote his note on Lavington Park (see p. 410) Mr. F. STREETER was gardener there, but before the article was published Mr. STREETER had taken up a fresh appointment at Caldecote Tower Gardens, Bushey Heath, Herts, and Mr. EDWARD W. FULLER has succeeded him at Lavington Park.

GIFT OF BOOKS.—With the view of encouraging an interest in horticultural and agricultural literature, Sir JOHN F. DEWAR, M.P. for Inverness-shire, has generously placed at the disposal of the educational authorities of that county a sum of money for the purpose of providing a supply of books on these subjects for school libraries.

FRUIT AND POTATO AND HOP CROPS IN FRANCE.—H.M. Consul-General at Paris, in a report dated June 18, states that the prospects for all kinds of Plums and Apricots are good, and a heavy crop might have been expected had it not been for the heavy rains of the past fortnight causing much fruit to fall. Prospects for Apples and Pears are fairly good. The area under Apples and Pears for cider and perry is officially estimated at 31,370 acres. The area under Potatoes is placed at 3,842,650 acres, compared with 3,678,990 acres in 1913, and that under

Hops at 7,321 acres compared with 7,054 acres. The condition of both crops was from fairly good to good.

THE CROPS AT HOME.—The Crop Reporters of the Board of Agriculture and Fisheries, in reporting on agricultural conditions in England and Wales on June 1, state that Wheat is very generally a good plant and promising, and appears to be the best of the three cereals. Barley and Oats are less satisfactory, and the later sown corn especially is often a thin plant. Both, and especially Oats, stand in need of rain. Only small differences are apparent in the acreage sown with spring crops as compared with last year, that of Barley and Oats each being smaller by perhaps 1 per cent. Beans are probably the most satisfactory crop of the year, although it was still uncertain whether the sharp frosts at the end of May affected them to any extent. Peas are generally looking very well, although weak in places. Early Potatoes have throughout the whole country, except in favoured situations, been cut by the sharp frosts at the end of May, and much damage has been done to them, while a serious consideration in their case is also that the date of lifting will be delayed. The main crop was hardly above ground, and appears practically everywhere to have escaped damage. The area under Potatoes is about the same as last year, but is rather greater in Lincolnshire. Mangolds, where up, appear to be a fair plant generally, though often irregular, and nearly everywhere backward. Turnip-sowing has been more forward than usual in the north, where, indeed, it is often completed. In the midlands and south, however, much less had been done, owing to the dry weather, and it had in many districts not even been begun. Rain was much needed for all roots. Hops were growing well in Kent until the cold spell checked them at the end of the month; in the western counties they were generally healthy, but had also been checked, and in some places damaged, by the frosts. Washing was becoming frequent in the western counties, but not much was being done in the south-east. An increase of about 3 per cent. in the area under Hops is reported, mostly in Kent. Fruit crops received a severe check from the widespread frosts at the end of May, and considerable damage was done to the trees and bushes. In many cases it was, however, too early to see how much harm had been done. Less damage appears to have resulted in Kent, and in the extreme south-west; but elsewhere both Strawberries and orchard fruit have suffered. As the effect of the sudden frosts, so near to the date of the reports, was still somewhat uncertain, prospective estimates of the yield must be very tentative. Strawberries appear about average, on the whole—though very different in different districts; Raspberries a little over average, Currants and Gooseberries average. Apples and Cherries are over average, particularly in the southern counties; Pears about average, and Plums rather below.

MELONS AT THE YORK SHOW.—The best scarlet-fleshed Melon at the York Show (see p. 446) was exhibited by the Rev. Marquis of NORMANBY, Mulgrave Castle, near Whitby (gr. Mr. J. CORBETT).

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

R.H.S. CHELSEA FLOWER SHOW.—At the close of the recent Chelsea Show the Council were told that a wish had been freely expressed that in future the show should last five days instead of three. It was further said that the majority of the exhibitors were in favour of this. In order to test the accuracy of this latter statement the Council ordered a vote of all the exhibitors of plants to be taken. They were asked to say which of the four following proposals they

favoured, marking each 1, 2, 3, 4, according to their order of preference:—(A) To extend the show to five days, viz., Thursday, Friday, Saturday, Monday, and Tuesday; (B) to extend to four days, Wednesday, Thursday, Friday and Saturday; (C) to make no alteration in the number of days, but to change to Wednesday, Thursday and Friday; (D) to make no alteration at all. 114 exhibitors of plants replied, and to the surprise of the Council only twenty placed suggestion A first. On an analysis of the votes and multiplying by three for the first favoured, by two for the second, by one for the third, and by half for the fourth, the following curious figures emerge:—229 votes were cast for C, 203 for B, 155 for B, and 112 for A. Considering the closeness of the voting for C and D, and bearing in mind the great inconvenience to all country exhibitors in adopting C (e.g., closing the show on Friday night with Saturday's early closing at the railway goods yards), the Council have decided

Rose Society to endeavour to bring about the constitution of an international committee to report on this subject. It seems to me that such a committee might perform a notable service by recommending the principles which should be adopted in any attempt to reform or improve our classification. I would not suggest that the National Rose Society should surrender its right to reclassify Roses; but rather that an international advisory committee should be formed and requested to draft, not a new classification, but a report on which, if it were found expedient, the National Rose Society might act. The future, no less than the present, has to be considered, and although, as you imply, convenience and rapidity of diagnosis are the first essentials of any system of classification, it would be a thousand pities if, with the constant intercrossing which is going on, our classification came to convey no hint whatever of the origin of our Roses. To compromise between

write this to add to the common stock of knowledge the little I know of their habitat in New Zealand and their frail hold of life in this country. Dry cold is not their bane, for they grow at home on the ridges and the high scree of the Southern Alps—from 4,000 to 7,000 or more feet above sea-level—on rocky, rubbly mountain sides, where, of course, the drainage is perfect—and while in winter these Alps are deeply snow-clad, in summer the sun is most powerful. What they, in common with many other tomentose Alpine plants cannot stand is our damp, wet, and often mild winters, producing too early growth. I have been working with them for the past four years—unsuccessfully in a large measure—but given good seed—which seems rare, even from their native haunts, for mine has all come straight from the Southern Alps—and a free, loose medium, they germinate in four weeks. Then the difficulty begins, when they have to be potted off into small pots. In these the happy medium of moisture seems hard to keep, and one by one they damp off at the collar. Of three dozen seedlings I raised last year of *Celmisia Lyallii*, only three or four are now alive! It would be very acceptable, no doubt, to many of your readers if Mr. Reuthe would kindly give through your journal some notes as to how he has succeeded with *C. Munroi*, for a well-known and good gardener told me he has repeatedly lost every plant of *Celmisia* he has tried. This is very disappointing. Yet a keen gardener does not like to be worsted by a mere Daisy! In Laing and Blackwell's *Plants of New Zealand* the following species are given:—*C. argentea*, *C. coriacea*, *C. laricifolia*, *C. lateralis*, *C. Lechleri*, *C. longifolia*, *C. Lyallii*, *C. Mackanii*, *C. sessiliflora*, *C. Traversii*, *C. vernicosa*. Besides these given by L. and B., I have had the following sent me from New Zealand:—*C. Petrici*, *C. sp.* "with brownish leaves," *C. coriacea*, "golden foliage," *C. Walkeri*, and I believe there are many more not yet identified. *Western Wight*.

DAMAGE BY A THUNDERSTORM.—On Friday, the 19th inst., at 5 p.m., this district was visited by a severe thunder and hail storm, and this cemetery, which is of large extent, appears to have been in the centre of the storm tract. Not a plant of the many thousands used in the decoration of beds, borders, and graves escaped injury. In the case of hard-wooded plants, nothing is left but bare stems, in others they are cut down to the ground. In many cases the plants have the appearance of having been attacked by swarms of insects and stripped of all their leaves. A cartload of debris has already been collected, and much more remains to be gathered. Many of the hailstones were $\frac{1}{2}$ inch in thickness, others of a flat shape and as large as a two-shilling piece, while many had the appearance of large jagged pieces of ice. At the rear of my house the hailstones rolled off the roof and collected to a depth of 8 inches, and at the back of our stables to a depth of 14 inches. On the roof of the crematorium the hailstones collected the depth of the stone coping and for 3 feet up the roof. The ground under the fruit trees and bushes in my garden was strewn with fruit, and scarcely a vegetable of any sort escaped destruction. Before the storm abated the neighbourhood was enveloped in thick mist, which lasted most of the evening. *J. D. Robertson, Superintendent, City of London Cemetery, Little Ilford, Essex.*

HARDINESS OF TRICYRTIS STOLONIFERA.—You mention on p. 421, as "apparently not perfectly hardy." *Tricyrtis stolonifera*, a plant introduced by me from Formosa. This was my own impression until now, but I find a plant which I put out last year under a north wall has survived over 20° of frost, which killed it to the ground; and though I had 10° of frost as late as May 26, it is again throwing up stems from the stolons. Considering that the seeds were gathered in a place where frost must be quite unknown, this has surprised me very much. I may add that in the greenhouse it remains in growth and flowers from March onwards. I shall be able to supply seeds or plants to anyone who may be interested. Prof. Somerville writes to say (see p. 400) that he grows *Oxalis adenophylla* in a retaining limestone wall, and that some leaves "are appearing

FIG. 208.—ODONTOGLOSSUM "RING ARTHUR": SEPALS AND PETALS WHITE WITH CLARET-RED BLOTCHES.

(R.H.S. First-Class Certificate on June 16, 1914—see p. 442).

to give their casting vote for D. The Council fully recognise that many of the Fellows and vast numbers of the public would like an extension of days, but in this matter they have considered it their duty to have respect chiefly to the owners and exhibitors of the plants; hence their decision to make no change at present. For if the conditions of a show are made too burdensome and expensive to the owners of valuable plants, they will cease to respond to the invitation to exhibit their treasures, and the show would gradually deteriorate in quality even if quantity were maintained by admitting inferior material. *W. Wilks, Secretary.*

CLASSIFICATION OF ROSES.—Whilst reading with interest your article on the classification of Roses, it occurred to me to enquire whether it would not be possible as a first step toward such a classification for the National

these two ends—convenience and historical significance—is admittedly a difficult task, and one quite beyond the powers of the writer of this letter. Nevertheless, whilst many of the great hybridisers are yet with us, a serious attempt at compromise should be made. If the international committee failed to agree no harm would be done; for rosarians, at all events, know how to disagree with urbanity and mutual respect. If, on the other hand, the basis of agreement were found, it would set an example in the horticultural world which would have far-reaching and important effects. *Blue Rose.*

CELMISIA.—The note on *Celmisia Munroi*, (see p. 440) is interesting, and as there still seems too much confusion as to the species—and, apparently, much ignorance as to the best way of cultivating these elusive plants—I

in a joint of the wall half a foot from the main plant." I introduced this plant from the Andes in 1902, and am even more surprised to hear of his success under conditions so absolutely unlike those of its native habitat, especially as I have lost it when planted out in a crevice of a limestone rockery. The only place where I found it was on the edge of an Alpine rivulet, at 6,000 feet elevation, in a volcanic soil, and though the heat was great in the day, there was frost at night in the height of summer. In winter the plant must be covered with snow, as the snowfall is very heavy in that region. On the plants I have grown in pots no sign of a stoloniferous habit has ever appeared. I showed this plant, in first-class condition, among other new ones of my own introduction, two years ago at the International Show, when it was not considered worthy of an Award of Merit, but I see it has lately received this well-deserved distinction when shown by a nurseryman. Can anyone tell me where to procure a very curious plant which I lately saw in flower in a Cornish garden under the name of *Rheum Alexandrae*, a species which I find was described by Batalin in 1894 from China? It reminded me of a miniature of *Rheum nobile*, one of the most striking Alpine plants in the world, and also, I fear, one of the most difficult to cultivate. *H. J. Elwes, Colesborne, Gloucestershire.*

SEVERING OF IVY STEMS (see pp. 422, 435).—I have known an instance of Ivy growing at least two summers after being severed from the main stem. The plant was growing on a brick wall in the kitchen garden at Little Onn, Stafford, and a thick piece that had grown through an old doorway and taken possession of the other side of the wall was cut through. For all I know the tree may have lived longer than two years, for it was alive when I left there. *W. Marsh, Morkeaton, Derby.*

—Mr. Biddlesden will no doubt be interested to know that the Ivy on Riddlesworth Church tower has been completely severed. On making inquiries I was surprised to learn that the stem was cut through 20 years ago. The height of the tower is 50 feet, three sides of which is nearly covered with Ivy looking quite green, and seeming as though it may defy its executioner another 20 years. I observed to-day that the tree is making new growth, and a passer-by would never imagine it to be cut through. I might add that the Ivy is planted on the north side of the tower. *H. Saville.*

—Some years ago a Mr. Lovesay, of the Paragon, Streatham, severed a large plant of Ivy which was growing over the back of two houses there, and the plant certainly looked nearly as well 18 months after as before he interfered with it. There is no doubt but that the stem was completely severed, as a portion some 6 inches long was removed from the stem, which was very thick, and as there was an area and stone-paved yard there, there was no possibility of any roots having been missed. *E. Jones.*

GRASS IN THE ROCKERY.—I was surprised to read on p. 435 Mr. Wood advocating grass for the purpose of growing Gentians and *Primula farinosa*. I do not think any practical purpose would be served by his suggestion of a shallow peaty stratum on a solid bed of soft magnesian limestone; I would suggest that peat is altogether a wrong compost for the cultivation of *Gentiana verna*. As to Mr. Wood having succeeded a second season with his experiment, I would urge that it is one thing growing such plants in boxes or pans with grass seed sown over for exhibition purposes, but quite a different one to advocate such a procedure on a more extensive scale in the rock garden. The best way I ever saw *Gentiana verna* grown was among *Thymus serpyllifolius*, which is superior to grass for such purposes, but whether in time it would overgrow the Gentians would be interesting to know. For the present there is much speculation as to which is the best plant for such purposes, but I consider the old way will be again adopted, i.e., to top-dress three or four times a year with fine soil in order to keep the growths just above the surface. Is this too much trouble, or why do people wish to introduce lawns into the rock garden? *N. Gardner.*

SOCIETIES.

ROYAL HORTICULTURAL.

(Concluded from p. 443.)

Floral Committee.

Present: H. B. May Esq. (in the chair), Messrs. W. A. Bilney, W. J. Bean, E. H. Jenkins, F. W. Harvey, F. Page Roberts, J. F. McLeod, C. R. Fielder, James Hudson, Chas. T. Drury, G. Reuthe, J. W. Moorman, Thomas Stevenson, J. W. Barr, C. Blick, John Dickson, Chas. Dixon, H. J. Jones, Edward Mawley, Chas. E. Shea, Chas. E. Pearson, W. P. Thomson, W. Cuthbertson, George Paul, J. T. Bennett-Poë, R. Hooper Pearson, Arthur Turner, W. G. Baker, Wm. Howe, and J. Jennings.

Messrs. B. R. CANT AND SONS, Colchester, again exhibited the beautiful single Rose, Cupid. Other desirable single varieties were Irish Glory, Irish Elegance and Maharajah. (Silver-gilt Flora Medal.)

Messrs. FRANK CANT AND CO., Colchester, filled tall stands with such Roses as Tea Rambler, François Guillot, Diabolo and Gardenia, and arranged vases of Irish Glory, Lady Curzon, Rayon d'Or, and others. (Silver Flora Medal.)

Messrs. PAUL AND SON, Cheshunt, included such varieties as Naiad, Mme. Edouard Herriot, Burning Bush, Mme. Mélanie Soupert and Lady Ashtown, in a praiseworthy collection of cut Roses. (Silver Banksian Medal.)

Messrs. STUART LOW AND CO., Bush Hill Park, Enfield, displayed many Roses, which included beautiful stands of Rayon d'Or, Liberty, Frau Karl Druschki, Edward Mawley and Lady Pirrie. Besides the Roses Messrs. LOW AND CO. showed a collection of Carnations, including many standard varieties in fresh and bright condition. (Silver Banksian Medal.)

Mr. ELISHA J. HICKS, Hurst, Berks, exhibited large vases of splendid blooms of Mr. Geo. Norwood, Princess Mary and Mrs. Charles Reed, and unusually good branches of Rosa Moysesii. (Bronze Banksian Medal.)

Mr. WALTER EASLEA, Leigh-on-Sea, also exhibited cut Roses.

Mr. H. BURNETT, Guernsey, exhibited a magnificent collection of Carnation blooms (Silver Flora Medal), and Mr. C. ENGELMANN, Saffron Walden, arranged a stand of Carnations. (Silver Banksian Medal.)

Mr. JAMES BOX, Haywards Heath, who was the only exhibitor of a collection of Sweet Peas, showed many excellent varieties. This exhibit participated in the award of a Silver Flora Medal.

Mr. G. REUTHE, Keston, Kent, contributed his customary exhibit of uncommon plants and shrubs.

The LISSADELL HARDY PLANT NURSERY CO., Sligo, exhibited excellent hybrid Primulas, of which *Primula Alannah* (*Bulleiana* × *Beesiana*), bearing strong spikes, with whorls of coppery-red flowers, which have golden centres, and *P. Asthore*, the same cross, but which has flowers of old-rose colour, were splendid. (Bronze Banksian Medal.)

Messrs. JOHN WATERER, SONS AND CRISP, Liverpool Street Arcade, London, showed border flowers and a neat rock-garden, which contained *Genista humifusa*, *Potentilla nitida alba*, *Asperula hirta*, *Mazus Pumilio* and similar plants. (Silver Banksian Medal.)

Messrs. R. TUCKER AND SONS, Oxford, built a very pleasing rockery. (Bronze Flora Medal.)

Messrs. KELWAY AND SONS, Langport, Somerset, again showed double herbaceous Paeonies in such splendid varieties as Dorothy Kelway, Paderewski, Lady Curzon, and Lady Alexandra Duff. The exhibit also contained good Delphiniums. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, filled a length of tabling with a rockery exhibit and border flowers. (Silver Banksian Medal.)

Mr. JAMES BOX, Haywards Heath, filled his customary corner of the hall with a group of magnificent herbaceous flowers. (Silver Flora Medal.)

Messrs. W. T. WARE, LTD., Feltham, contributed many herbaceous Paeonies and Delphiniums in a collection of border flowers. (Silver Banksian Medal.)

Messrs. R. H. BATH, LTD., Wisbech, specialised in herbaceous Paeonies, of which they showed gorgeous blooms of Marshal Oyama, Mandarin, Duchesse d'Orléans, and General Nogi. (Silver Flora Medal.)

Messrs. J. PIPER AND SONS, Bayswater, had an attractive arrangement of border flower and rockery plants. Amongst the latter were *Erodium Reichardii*, *Androsace lanuginosa*, *Pratia linnaeoides*, and *Gentiana dahurica*. (Bronze Banksian Medal.)

Messrs. BLACKMORE AND LANGDON, Bath, displayed a collection of exceedingly well-grown Delphiniums. At one end of the Delphiniums they showed *Begonia semperflorens virginialis*, a strong growing variety, which would be useful for growing in pots, as well as for summer bedding. (Silver Banksian Medal.)

Messrs. BARR AND SONS, Covent Garden, London, displayed bold masses of Delphiniums, Paeonies, Lupins, and Lilliums, with an attractive bordering of *Nepeta Mussinii*. (Silver Banksian Medal.)

Messrs. R. WALLACE AND CO., Colchester, included in a miscellaneous collection of border flowers cut blooms of *Lilium marmoratum aureum*, *L. sanguineum*, *L. Golden Gleam*, *Brodiaea ixioides*, and *B. capitata*. (Silver Banksian Medal.)

Messrs. BUNYARD AND CO., Maidstone, set up very fine vases of attractive herbaceous Paeonies, chiefly of such double-flowered varieties as Marquise of Lorne and Comte de Paris. (Bronze Banksian Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants, included floriferous plants of *Mitraria coccinea*, *Wahlenbergia vincaeflora*, and *Hemerocallis aurantiaca major*, amongst a collection of Delphiniums. (Silver Banksian Medal.)

Mr. G. FERGUSON, The Hollies, Weybridge (gr. Mr. F. W. Smith), showed Delphiniums. (Silver-gilt Banksian Medal.)

Mr. AMOS PERRY, Enfield, arranged *Thalictrum aquilegifolium compactum*, *Isatis glauca*, *Arenaria plantaginea gigantea*, *Gillenia trifoliata*, and many varieties of *Papaver orientalis*. (Silver Flora Medal.)

Messrs. GEO. JACKMAN AND SON, Woking, contributed many excellent herbaceous flowers, and a large quantity of a pretty border Pink named Elsie. (Silver Banksian Medal.)

Messrs. FRED. SMITH AND CO., Woodbridge, arranged cut blooms of *Gaillardias*, *Anchusa Opal*, and Oriental Poppies. (Silver Flora Medal.)

Hardy flowers were also shown by Mr. VERNON T. HULL, Langport, Bristol (Bronze Banksian Medal), Messrs. THOMPSON AND CHARMAN, Adam Street, London (Bronze Banksian Medal), Messrs. G. and A. CLARK (Dover), Messrs. CARTER, PAGE AND CO. (London Wall, London), the Misses HOPKINS (Shepperton-on-Thames), and Mr. E. A. T. TURNER (Enfield).

Messrs. WM. CUTBUSH AND SON, Highgate, contributed interesting varieties of *Hydrangea hortensis*. The collection of plants also included beautiful Crozy Camas and Gloxinias. (Bronze Banksian Medal.)

Messrs. WILLIS AND SGAR, Onslow Crescent, London, also showed various *Hydrangeas*.

Messrs. J. VEITCH AND SONS, LTD., Chelsea, exhibited splendid plants of *Elaeocarpus*, literally wreathed in bloom. (Bronze Flora Medal.)

Messrs. H. B. MAY AND SONS, Upper Edmon-ton, had many exceedingly good standard plants of *Lantana*, *Fuchsia*, *Heliotrope*, and *Lippia citriodora*, arranged over dwarf flowering plants and hardy Ferns. (Silver Flora Medal.)

Fruit and Vegetable Committee.

Present: C. G. A. Nix, Esq. in the chair, Messrs. W. Bates, Edwin Beckett, H. Markham, A. R. Allen, F. Perkins, W. E. Humphreys, Horace J. Wright, P. C. M. Veitch, A. Bullock, J. Jacques, J. Willard, Wm. Pope, A. Grubb, and A. W. Metcalfe.

Messrs. J. VEITCH AND SONS, Chelsea, arranged a magnificent collection of pot fruits on a large floor space. At the back there were fan-shaped Peach trees, with each branch trained with almost mathematical exactitude. Not only were the trees—no matter what their shapes—well balanced and symmetri-

cal, but they all bore full crops of perfect fruits; all, except on the bush trees of Jefferson's Plum, being ripe and ready for the table. The principal varieties of Peach were Amsden June, Early Alexander, and Hales's Early. Nectarine Cardinal was represented by several trees, and in the front of this splendid exhibit there was a small bush of Cherry Bigarreau de Schrecken, bearing more fruit than we remember having seen on a pot Cherry of its size. (Gold Medal.)

Messrs. G. BUNYARD AND SONS, Maidstone, Kent, exhibited a very fine collection of Cherries in pots. These were large bushes, and all bore ripe fruits of good size and luscious appearance. The chief of the red-skinned sorts were Governor Wood, Elton Heart, and Napoleon Bigarreau, whilst amongst the black varieties Werder's Early Black and Black Tartaricas were equally as fine. (Silver-gilt Banksian medal.)

SWANLEY HORTICULTURAL COLLEGE was awarded a Silver Banksian Medal for soft fruit packed in attractive manner, so as to travel unbruised, either by rail or post. Each of the eight Peaches had a strip of cotton wool wound around it, and was embedded in the same substance sufficiently to keep it steady, but exposing about one-third. The fruit had travelled perfectly, but the box was so large as to give the fruits a meagre appearance.

Messrs. BARR AND SONS, Covent Garden, London, set up a collection of splendid seasonable vegetables arranged in the best exhibition manner. The heads of Cauliflowers were of perfect shape and as pure a white as possible, and the Cabbages, Carrots, Peas, Beans, and Tomatos were equally good. (Silver-gilt Knightian Medal.)

TRIAL OF AQUILEGIAS.

A Sub-Committee of the Floral Committee recently visited Wisley, and recommended the following awards to strains of Aquilegias now on trial, which were confirmed by the Council of the R.H.S. on June 16.

HIGHLY COMMENDED.

Aquilegia corulea hybrida, from Messrs. VEITCH, Exeter.

Aquilegia New Rose shades, from Messrs. BARR, Covent Garden.

Aquilegia Long Spurred Hybrids, from SIMPSON AND SONS, Birmingham.

Aquilegia canadensis Turk's Cap, from Messrs. BARR, Covent Garden.

COMMENDED.

Aquilegia Haylodgensis delicatissima, from Messrs. R. VEITCH, Exeter.

Aquilegia New Hybrids, from Messrs. R. SYDENHAM, Birmingham.

Aquilegia coerulea White Lady, from Messrs. BARR, Covent Garden.

Aquilegia Munstead White, from Messrs. BARR, Covent Garden.

The late May frost had caught the majority of plants under trial, unfortunately rendering them unsuitable for consideration by the Sub-Committee. W. Wilks, Secretary.

NATIONAL ROSE.

CONFERENCE AT THE WHITE CITY.

JUNE 23.—There was a gratifying attendance at the conference held at Shepherd's Bush on the above date. Mr. Chas. E. Shea presided. After a few remarks concerning the objects of the conference, he informed the meeting that he had received a telegram from Mr. E. G. Hill expressing his inability to give his promised paper on "The Position of the Rose in America." Mr. H. R. Darlington then proceeded to give his lecture on "One Hundred Years of Progress in the Development of the Rose." He reviewed the enormous increase in the numbers of varieties and the improvement which has been effected in the Rose during the past century. There was a certain difficulty in arriving at the precise number of varieties that were in cultivation a hundred years ago, because then, as now, names

in the trade lists did not always represent distinct varieties; he felt sure that more care was now exercised in this respect than formerly. In 1815 there were probably 200 varieties; two years later the Noisette Rose was raised in America by Philip Noisette, who sent it to his brother in Paris for propagation. This variety, which would be of great interest, the lecturer feared had entirely disappeared. Two years later saw the advent of the perpetual Damask Rose. From that time numbers increased at the average rate of 176 per year, so that by 1858 there were some 2,500 varieties in cultivation. In 1906 the number swelled to 11,000, and at the present time there were probably 12,000 varieties. Whilst the increase in numbers had been at a fairly steady rate the development of new groups had been intermittent.

The Rev. J. H. PEMBERTON spoke of the great impetus which has been given to the raising of new groups and varieties by ladies, and the greatest credit was due to the Empress Josephine, who set a fashion in France which continues throughout the temperate world. In those days, he said, collections of various plants, notably Tulips, were the fashion, but the Rose in this respect had not been considered, so the Empress caused a rosary to be formed, and planted there specimens of the 250 varieties then in cultivation, whilst her gardener set to work to raise new sorts. Mr. Pemberton, mentioning the name of Noisette, the raiser of the group which is immortalised by his name, appealed for official recognition to the group Pernetiana, which would give due credit to the French raiser, to whom the world is indebted for so many beautiful Roses. What was now wanted in the Rose was colour and freedom of flowering, such as were found in Prince de Bulgarie, Joseph Hill, Mme. Abel Chatenay, and also H.P. varieties, which will be as good in autumn as the present sorts are in summer. Whilst all rosarians are, he continued, sensible of the great work done by specialists in France and America, we must not overlook the strong claims of our English and Irish Rose growers.

Mr. E. J. HOLLAND fully agreed with the concluding remark of the last speaker, and said that, whilst we, as a nation, were slow in taking up any fresh pursuit, we afterwards entered into it heart and soul, and so soon made up the leeway. He also spoke of the great difficulty, due to crossing and intercrossing, in defining an H.T. Rose, and frankly admitted his own inability. With regard to the development of the Rose during his own recollections, he gave the palm to Crimson Rambler, a variety which changed the whole style of Rose-growing. He was of the opinion that our pressing need was for the perfect crimson and then the perfect yellow Rose.

Mr. FRANK CANT disagreed with a previous speaker, and contended that the supply created the demand, and instanced the new Roses on show in the building. The Roses of forty years ago, he said, compared badly with the beautiful varieties of to-day, and such varieties as John Hopper, Duchess of Vallembrosa, Souvenir de la Malmaison and Victor Verdier, which were considered indispensable exhibition varieties thirty years ago, were rarely seen at the present time.

Mr. EDWARD MAWLEY claimed that the National Rose Society had done very important work in developing the present love of Roses. In 1884, when the first official catalogue was compiled, it included 600 varieties, of which only eighty-one now find a place. He reminded the meeting that during the past sixteen years we had escaped severe winters, and remarked that he was of the opinion that many of the new Roses would not prove to be really hardy. The "Butterfly" Roses—those which had but few petals and no lasting qualities, should, he contended, be discouraged. He paid a tribute to the memory and work of the late Mr. George Gordon.

The following awards were made for exhibits of Roses arranged around the lecture hall.

Silver-gilt Medals to Messrs. B. R. CANT and Co., and Mr. E. J. HICKS. Large Silver Medals to Messrs. FRANK CANT AND Co. and Mr. GEORGE PRINCE. Silver Medals to the Rev. J. H. PEMBERTON, Messrs. C. C. WILLIAMSON, STUART LOW AND Co., and BURRELL BROS. Bronze Medals to Mrs. C. C. WILLIAMSON, Mr. H. S. BARTLETT, and Messrs. MORRIS BROS.

SOME ASPECTS OF MODERN GARDENING.

(Continued from page 444.)

MR. R. W. WALLACE continued his paper as follows:—

In addition to Irises, there are, of course, many other plants suitable for cultivation in the wild garden, and I would emphasise the use of Verbascons, particularly *V. vernale*, *V. Caledonia*, *V. densiflorum*, *V. phlomoidees* (the leaves of this species are splendid), and the new Warley Rose variety when possible to acquire it. Verbascons should be grouped in irregular masses with occasional solitary specimens apart from the main planting. If they can be used near any old spreading Yews, their tall spikes against the dark background will tell. Campanulas, such as *C. macrantha* and *C. alliariaefolia*; Columbines, the tall *Centaurea ruthenica* and *C. macrocephala*, *Paeonies* (particularly the European species), *Rudbeckias*, and *Michaelmas Daisies*, are other fine wild garden plants.

Epilobium angustifolium (Willow Herb) in sandy soil is a glorious plant, as one often sees it growing in dense masses round Woking, with the dark Pine background. *Linaria dalmatica*, a splendid, tall-growing form of the Tead Flax, with glaucous foliage and yellow flowers, seeds itself in the grass: *Thalictrum* (Meadow Rue), the tall forms of *T. aquilegifolium* in shades of pink, purple and white, with their fine-cut foliage are delightful in the misty effect they produce when grouped in irregular masses. *Thermopsis montana* (the yellow Californian Lupin), flowering at the same time as the foregoing, may be grown near the *Thalictrums*, one colour helping the other; for a waste piece of poor, stony ground, if it is anywhere near a frequented spot, make good use of the Evening Primrose (*Oenothera Lamarckiana*). Its clear yellow flowers shine out in the twilight like stars, and on a succeeding dull morning the flowers last till noon time.

Time prevents me from more than mentioning the use of spring-flowering bulbs in grass, *Chionodoxas*, *Scillas*, *Daffodils*, *Fritillarias* and *Tulips*.

Now, leaving the open ground, let us pass into the woodland. Here it is essential that the tree growth be not too dense, and the trees be largely deciduous. If one is possessed of a wood where Oaks abound, with some Birch and Beech, and an occasional Scotch Fir and undergrowth of Hazel and Ash, which may be cleared as required, and in addition if a stream or streams running through, and damp places abound, then there is really no limit to opportunity.

Here in the cool recesses of the wood can be massed exotic Primulas, following the examples shown us in the planting of our native Primrose. Full use should be made of *P. denticulata* in its many shades, coming into flower early in February, followed by *P. rosea*, *P. japonica*, *P. pulverulenta*, *P. Bulleyana*, and *P. sikkimensis* in broad masses, also in groups and scattered plantings by the stream-side. This will carry on the effect until June, and the Primulas seed naturally and increase without difficulty. In open clearings masses of *Azaleas* and *Rhododendrons*, not overlooking *Rhododendron racemosum*, the small early-flowering pink Chinese species; and if the situation is favourable to the growth of the Himalayan species, your opportunity is to be envied, and you can also use many of the forms of *Azalea amoena* and the Japanese forms, including *rosaeflora*.

Associated with these will be found congenial spots for many *Liliums*, especially *L. giganteum*. This noble Himalayan species is rightly placed in the wood. It grows magnificently in the woods at Caer Hays Castle here, in scattered colonies, some comprising forty to fifty flower-spikes, 10 to 15 feet in height, carrying many flowers; and to descend quickly from the tallest species to one of the smallest, do not omit *Lilium rubellum*, a diminutive pink species, which delights to grow in semi-shade amongst the roots of low-growing

shrubs, and has been so beautiful at Wisley this summer.

Other species of *Lilium* to be prized are *L. Szovitzianum* and the Martagons, which require open and sunny positions either in small clearings or on the fringe and approaches to the wood. The Californian Panther Lily and its forms should be planted in sandy pockets, well drained, by the stream. With it we may use *L. canadense* and *L. superbum*. I will not name more for general use in the woodland, because so much depends on the soil and situation of the site. But one can always find some members of this lovely family capable of thriving in any woodland scheme.

If your wood is dense, then you must clear out some open grassy ways, and let the principal ones be fairly straight, and not serpentine, because, above all, you want to see into the woodland, and get the distant effect of light and shade. An occasional fine tree trunk or group of stems makes a splendid termination to a vista or a centre for tracks to cross; on either side of the green ways there must be informal groupings, saving what is best of the natural growth, and adding to it.

The use of free-growing Roses in informal masses, such as The Garland, Carmine Pillar, Una and Penance Briers, which only require a little thinning and cutting back. These will form large mounds, and running up adjacent trees, cascades of flowers. Plant also Clematis of the montana type, and flammula and viticella forms. I would have the planting of my broad vistas dealt with in rather a bold way, using large subjects, and plenty of them, and then from these broad vistas many smaller paths, which would lead to the quieter parts of the wood, such as a group of Silver Birches that stand in a small clearing.

Here, all around, I would mass many of the beautiful forms of Lady Ferns, Polystichums, and others, amongst them Foxgloves and occasional Mulleins, and a few *Lilium Szovitzianum* and *L. Martagon album*. There will be colonies of Cyclamen, both spring and autumn, and on one side a low carpet of *Gaultheria procumbens*, from which would rise the taller species *G. Shallon*, Honeysuckle in masses, and, perhaps, one Rose in a tangled mass of beauty from behind a group of *Cytisus praecox*, carpeted with the double lilac Primrose, now long past its beauty.

Besides British Ferns, use freely some of the North American species, such as the *Oncoclea struthiopteris*, Ostrich Fern (*Osmunda claytoniana*), the Crozier Fern, and *Osmunda cinnamomea*, not forgetting our own Royal Fern for damp spaces and hollows, also the Hardy Canadian Maidenhair Fern (*Adiantum pedatum*).

Associated with these Ferns, the better forms of the wood Anemone and the North American Trilliums and Dog's Tooth Violets can be freely used.

I know of no finer plant for individual effect in the open woodland than a colony of the blue Himalayan Poppy, *Meconopsis Wallichii*. Choose a position fairly damp, where the woodland is thin, and yet affords shelter from wind, and here you may plant it, and from the day its foliage begins to form until possibly eighteen months or two years later, when the stem has developed to a height of 8 feet, or the last pearly blue flower has faded, it will be an object of beauty. The effect of many spikes of shimmering pale opalescent blue flowers, and the foliage on damp days studded with drops of water like diamonds, is irresistibly lovely.

If your wood should by any chance contain peat then great will be your opportunity with such glorious plants as *Kalmias*, *Pernettyas*, *Andromedas*, *Epigaea*, *Shortia*, *Schizocodon*, *Galax*, and hosts of other peat-lovers. Of other woodland plants I have not time to speak, but, according to your surroundings, you can use Broom, Gorse, Heather, *Cistus*, in open, sunny spots on gravel. In cool recesses, *Funkias*, *Convallaria*, *Tiarella*, *Trillium*, *Epimedium*, the small habited Ferns, *Asperula*, etc. Such lists as this might be indefinitely extended, but I fear would only weary my audience, and I have thought it best to dwell on a few points in rather greater detail, as it is the method of planning I have tried to explain.

(To be concluded.)

BIRMINGHAM BOTANICAL AND HORTICULTURAL.

JUNE 11.—The above society's annual show of Orchids and other flowers was held at the Botanical Gardens, Edgbaston, on this date. Although the entries were hardly so numerous as those of a year ago, the Exhibition Hall presented a very pretty sight. Orchids were arranged along two sides of the hall, and table decorations filled the centre floor.

Messrs. JAMES CYPHER AND SONS, Cheltenham, had a pleasingly arranged group of Orchids, which included some very well grown *Odontoglossums*, with long, arching spikes of bold, shapely flowers of great substance; also *Cattleya gigas*, *C. imperialis*, *Laelio-Cattleya Helius*, *L.-C. Cappel*, and excellent specimens of *Odontioda Lambeauianum*, *O. Lutetia*, and *O. Boltonii*. *Cypripediums* were represented by *C. callosum* *Sanderæ*, *C. bellatulum album*, and *C. niveum*. The dainty little *Bulbophyllum barbigerrum* attracted attention. *Masdevallias* and varieties of *Miltonia vexillaria*, *Phalaenopsis*, *Dendrobium Thwaitesiae*, *Anguloa Ruckeri*, and a profusely flowered plant of *Dendrochilum latifolia* were also included in this attractive exhibit. (Silver-gilt Medal.)

Mr. EDWARD V. LOW, Vale Bridge, Haywards Heath, sent eighteen choice Orchids—principally hybrids—of which the following were specially meritorious:—*Cattleya Mossiae Arnoldiana*, *Odontoglossum crispum xanthotes Walkeræ* (see Awards), *Laelio-Cattleya Aphrodite*, *L.-C. Cowanii*, and *L.-C. Canhamiana alba*. (Bronze Medal.)

W. WATERS BUTLER, Esq., Southfield, Edgbaston (gr. Mr. R. H. Jones), contributed a group of Orchids remarkable for the extent, variety, and excellent condition of the specimens exhibited. It is only possible to mention a few of the many good things included in this fine display, which was rich in varieties of *Miltonia*, many of the specimens carrying upwards of a dozen long flower-spikes. The varieties *Bleuana*, *Bellissima*, *G. D. Owen*, *gigantea*, and *Empress Victoria Augusta* were strikingly beautiful. *Laelia purpurata*, and *L. p. Mrs. R. A. H. Mitchell* had stout spikes, and huge, shapely flowers. A plant of *Laelio-Cattleya eximia*, with a strong spike, carried four huge well-formed blooms, and *L.-C. Iolanthe* had eight very fine flowers, with a beautifully frilled lip. Other good *Laelio-Cattleyas* were *L.-C. Gottoiana Southfield Variety* (see Awards), *L.-C. Gottoiana The President*, and *L.-C. Canhamiana*. *Odontoglossums* were used with charming effect, especially those in the upper part of the group, where graceful Bamboos and Palms formed a pleasing setting to the long flower-spikes. Excellent examples of *O. eximium* *E. C. Rogerson*, with fifteen large flowers, *O. ardentissimum Sanderæ*, *O. a. Prince of Wales*, with sixteen shapely flowers, *O. crispum* *G. F. Moore* (good spotted form), *O. Pescatorei*, and its beautiful variety *Grand Duchess* were well shown. *Cymbidiums* were represented by upwards of twenty large plants; the long flower-spikes were allowed to hang over and mingle with the adjacent subjects. *Odontioda Lambeauiana* (extra good), *Cypripediums*, *Cattleya gigas* *J. Charlesworth*, *C. intermedia* *White Queen*, *C. Mendelii* *Southfield Variety*, and other choice varieties; *Oncidiums*, *Phalaenopsis*, *Vandas*, *Thunias*, and *Masdevallias* were represented by profusely flowered specimens. (Gold Medal.)

Messrs. SANDER AND SONS, St. Albans, exhibited a large assortment of Orchids, in which *Odontoglossum crispum*, *O. Wilkeanum*, *O. eximium*, and *O. ardentissimum* were noteworthy. *Laelio-Cattleya Fascinator*, *L.-C. Sylph*, *L.-C. Martinetii*, *Sunburst*, *Brasso-Cattleya Empress of India*, and *Dendrobium cymbidioides* were well shown. *Masdevallias*, *Odontioda Charlesworthii*, *Bulbophyllum Lobbi*, and *Cypripedium caudatum* were also included. (Silver Medal.)

Messrs. STUART LOW AND CO., Bush Hill Park, Enfield, occupied the orchestra end of the Exhibition Hall with an arrangement of Carnations, Orchids, and Roses. The Carnations, which were displayed in large mounds or pyramids, and in vases of various sizes, were of good quality and beautifully fresh; they included

such varieties as *Baroness de Brien*, *Princess Juliana*, *Salmon King*, *Ceres*, *Mauveen*, and *Princess of Wales*. Of Orchids, *Ceologyne pandurata*, *Miltonias*, *Phalaenopsis*, *Odontiodas*, *Laelia Canhamiana*, *Dendrobiums*, *Remantheras*, and *Cattleyas* were the best. (Silver Gilt Medal.)

Messrs. BAKERS, Wolverhampton, had a large group of a very fine strain of *Columbines*, but unfortunately the heavy rains a few days prior to the show had disfigured many of the flowers. Messrs. BAKERS also showed a collection of *Iris*. (Bronze Medal.)

Mr. C. H. HERBERT, Acocks Green, had a group of miscellaneous plants and cut flowers, consisting principally of *Eurybia Gunniana*, *Pyrethrums*, *Saxifragas*, *Lupins*, *Pinks*, and *Oriental Poppies*. (Silver Medal.)

W. BYNG KENRICK, Esq., Metchley House, Edgbaston (gr. Mr. James Webb), sent a group of *Gloxinias*. The plants were well grown, and represented a very good strain. (Bronze Medal.)

Miss S. S. THOMPSON, Handsworth, sent an interesting collection of *Cacti*. (Bronze Medal.)

Messrs. ROBERT SYDENHAM, LTD., Birmingham, exhibited Spanish *Iris* and *Ranunculus*. (Bronze Medal.)

The Silver Medal offered by the National Viola and Pansy Society for the best vase of *Violas* in the show was won by Mr. A. BASTOCK, Hall Green, Birmingham. The variety exhibited was *Mrs. S. Mason*.

AWARDS.

AWARD OF MERIT.

Laelio-Cattleya Gottoiana Southfield Variety, from W. WATERS BUTLER, Esq., Edgbaston (gr. Mr. R. H. Jones).—A handsome form, with a strong spike, and five very large purple flowers with a velvety crimson, purple lip.

Odontoglossum perculum, from Messrs. JAMES CYPHER AND SONS, Cheltenham.—A splendid variety, with a long, arching spike, the large, pale, purplish-white flowers heavily spotted with chocolate-brown.

Odontoglossum Jasper, from Messrs. JAMES CYPHER AND SONS.—Flowers large, purple spotted, and marked with chocolate-brown.

Odontoglossum crispum xanthotes Walkeræ, from Mr. EDWARD V. LOW, Haywards Heath.—Large white flowers, spotted with yellow.

Pink "Eclipse", from Mr. C. H. HERBERT, Acocks Green.—A variety with large, Carnation-like flowers of a pleasing shade of pink, and very sweetly scented. The plant is said to be of strong habit and free in flowering.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MAY 28.—Committee present: R. Ashworth, Esq. (in the chair), Messrs. J. Bamber, J. J. Bolton, J. Cypher, A. G. Ellwood, J. Evans, A. Hanmer, Dr. Hartley, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, C. Parker, W. Shackleton, P. Smith and H. Arthur (secretary).

Messrs. CYPHER AND SONS, Cheltenham, were awarded a Silver Medal for a group.

Col. J. RUTHERFORD, M.P., Blackburn (gr. Mr. Lupton), staged a group to which a Silver Medal was awarded.

JOHN LEEMAN, Esq., Heaton Mersey (gr. Mr. Smith); O. O. WRIGLEY, Esq., Bury (gr. Mr. Rogers); WM. THOMSON, Esq., Walton Grange (gr. Mr. Howes); Messrs. A. J. KEELING AND SONS, Bradford; Messrs. CHARLESWORTH AND CO., Haywards Heath; Mr. W. SHACKLETON, Highfield, Bradford; Mr. D. McLEOD, Chorltoncum-Hardy; and Mr. J. EVANS, all contributed exhibits.

FIRST-CLASS CERTIFICATE.

Odontoglossum Promerens "Our King", a large well-set flower with dark purple markings, from WM. THOMSON, Esq.

AWARDS OF MERIT.

Odontoglossum Hereward and *O. x. Lander* (*Harryano-crispum* x *Mirum*), both from JOHN LEEMAN, Esq.

O. Amandum magnificum (*Wilkeanum* x *Pescatorei*), and *Odontioda Schroderæ*, both from Messrs. A. J. KEELING AND SONS.

Odontoglossum × *Edward Thompson*, from Wm. Thomson, Esq.

FIRST-CLASS (BOTANICAL).

Nanodes Medusae, from Messrs. A. J. Keeling and Sons.

ARRANGEMENTS FOR SPECIAL PRIZES.

The following competitions have been arranged:—The President's Cup and Prize to Gardener, for Cattleyas, Laelias, etc.; J. J. Bolton's Gold and Silver-Gilt Medals, with prizes to Gardeners, for Cypripediums; Evans' Silver Trophy and Prize to Gardener, for *Odontoglossum*s and their hybrids; Royal Botanic Society of Manchester's Gold Medal, for *Odontiodas*, *Miltonias*, etc.; A. Hammer's Silver Cup and Prize to Gardener, for most points during the session; P. Smith's Gold Medal and Prize to Gardener, for most points during the session; The Sander Prizes to Gardeners, for groups; Cypher's Gold Medal and Prize to Gardener, for arrangement; Charlesworth's *Objet d'Art*, for new awards; the Society's Medals will also be awarded as before.

Obituary.

PROFESSOR REYNOLDS GREEN, F.R.S.—We learn with regret of the death of Professor Reynolds Green, Hartley Lecturer on Vegetable Physiology in the University of Liverpool. Professor Green was among the pioneers in the biochemical investigation of plants. He made important contributions to our knowledge of plant enzymes, and was the author of several standard textbooks, all of which were characterised by a remarkable lucidity of expression. Professor Green held for many years the Professorship in Botany in the Pharmaceutical Society. He was elected to the Royal Society in 1895, and was President of the Botany section at the Belfast meeting of the British Association (1902).

JOHN PERKINS.—Readers will learn with regret of the death of Mr. John Perkins, on the 19th, at the age of 73. Deceased was the senior partner in the firm of Thomas Perkins and Sons, Northampton, and he had been in failing health for the last eighteen months. A native of Northampton, he commenced travelling at the age of 23, and continued to call upon the wholesale horticultural trade up to two years ago. The surviving partner (Mr. Fred Perkins), who has managed the outdoor departments of the nursery, will for a time control the business, with the aid of his two sons and two nephews. The late Mr. Perkins devoted a considerable time to the public service; he was Overseer of the Poor Law, a member of the Local Board, Urban District Council, Town Council, a county magistrate, trustee of charities, and a member of the Northants Agricultural Society. Mr. Perkins was twice married, and leaves a widow, two sons and a daughter.

THE LATE MR. GEORGE GORDON.—The funeral service of the late Mr. Gordon, which was conducted at the Kew parish church on June 18, was attended by many prominent horticulturists. Mrs. Gordon, supported by her son, Mr. Fred Gordon, her daughter and youngest son, were the chief mourners, and amongst those present were Sir David Prain, director of the Royal Gardens, Kew; Sir Harry J. Veitch and Mr. James Hudson (representing the Council of the R.H.S.); Messrs. Arthur Turner and Will Taylor (National Rose Society); Messrs. J. Ridg., J. A. Jarrett, J. T. West (National Dahlia Society); F. W. Harvey (National Sweet Pea Society and *The Gardener*); Mr. G. Collins Levey (Administrator of the Anglo-American Exposition); Mr. Chas. H. Curtis (*Gardeners' Magazine*); Mr. T. W. Sanders (*Amateur Gardening*); Mr. Horace J. Wright (*Journal of Horticulture*); Mr. H. H. Thomas (*The Gardener*); Mr. A. C. Bailliet (*Gardeners' Chronicle*); Messrs. Leonard Collingridge, O. Thomas, John Peal, Jos. Cheal, C. T. Druery, R. Pinches, D. McDonald, J. W. Moorman, G. W. Valentine, J. Emberson and G.

Davidson. Floral emblems were sent by the family, the Earl of Kintore and Administration of the White City, Horticultural Executive of the White City, Proprietors and Staff of the *Gardeners' Magazine*, Executives of Royal Gardeners' Orphan Fund, Horticultural Club, National Rose Society, National Sweet Pea Society and National Dahlia Society, and others. The interment was at Richmond Cemetery.

CALIFORNIAN PLANTS: *T. G. R.* *Lathyrus violaceus* has flowers about eight lines long, violet-blue in colour, the banner being veined with darker, nearly parallel veins. The flowers of *L. laetiflorus* are larger (about 11 lines long), but not so showy, being nearly white or faintly flesh-coloured, the banner veined, nearly as in *L. violaceus*, and suffused with bright pink at the back; the racemes are longer, and less compactly-flowered than in the former species. The plants of both species grow from 6 to 8 feet high, are abundantly covered with light-green foliage (there are about twelve small leaflets to each leaf), and are profuse flowerers, each leaf-axil bearing a raceme of ten to fourteen flowers. Both species grow wild in the mountains of Los Angeles co., Southern California. So far as we are aware *Delphinium Emiliae* is not in cultivation in this country; it is near to *D. variegatum* and should prove a valuable plant for the perennial flower border.

ELECTROCUTION OF GREEN FLY: *H. H., Co. Kilkenny.* There is no reason to doubt the accuracy of the statement that has appeared in the daily Press to the effect that green fly (aphis) may be killed by means of an electric discharge; nor is there much reason to doubt the possibility of so adjusting the strength of the current as to kill the fly without injuring the plant; but there is reason to doubt whether any gardener would find this method applicable in ordinary practice. The time taken to rid one plant by this means would be about equal to that required to spray 100 trees. Therefore, pending the further perfection of the method by electrocution, we recommend you to treat your Roses and other infested plants by means of sprays.

NAMES OF PLANTS: *W. T.* 1, *Carpenteria californica*; 2, *Rosa Moyesii*.—*J. A.* 1, *Phlomis fruticosa*; 2, *Carduus* sp., cannot name without flowers; 3, Garden variety of Rose, cannot match; 4, *Sedum rupestre*; 5, *Allium sphaerocephalum*; 6, *Veronica Teucrium*; 7, *Juniperus Sabina*.—*G. H. S.* 1, *Lilium pyrenaicum*; 2, *Coronilla varia*; 3, *Pernettya mucronata*; 4, *Pittosporum tenuifolium*; 5, *Buddleia globosa*; 6, *Helixine Soleirolii*; 7, *Anchusa semper-virens*.—*W. J. R.* 1, *Laelio-Cattleya albanensis* (*C. Warneri* × *L. grandis*). It first appeared as an imported plant (natural hybrid) with Messrs. Sander in 1893; 2, *Cattleya Mossiae*; 3, *Aërides crassifolium*; 4, *Dendrobium suavisimum*. There is little to separate this species from *D. chrysoxum*, except the dark blotch on the lip.—*F. W. Norris.* *Quisqualis indica*, a very common plant in the tropics.—*W. H. Sharpe.* *Olearia macrodonta*.—*T. S. N. G.* 1, *Onosma echioides*; 2, *Kalmia latifolia*; 3, *Polygonum alpinum*; 4, *Rhodotypos kerrioides*; 5, *Codonopsis ovata*; 6, *Deutzia crenata flore pleno*; 7, Too scrappy for identification; 8, Cannot name without flowers; 9, *Hydrangea petiolaris*; 10, *Escallonia langleyensis*; 11, *Amorpha canescens*; 12, *Amelanchier alnifolia*.—*E. G. J.* 1, *Spiraea canescens*; 2, *Lathyrus sativus* (annual); 3, *L. grandiflorus*.—*Newt.* 1, *Hesperis matronalis*; 2, *Valeriana Phu.*—*G. F.* *Galtonia candicans*.—*Cumbrian.* *Trifolium hybridum*, "Alsike Clover".—*Surrey.* *Lithospermum intermedium*.—*G. G.* A very pretty form of *Laelio-Cattleya Martinetii* (*L. tenebrosa* ×

C. Mossiae.—*F. M. F., Cambridge.* *Leycesteria formosa*.—*M. H.* 1, *Odontoglossum aspidorhinum*; 2, *Odontoglossum sceptrum*; 3, *Ada aurantiaca*; 4, *Bletia hyacinthina*.—*R. G.* 1, *Nephridium molle*; 2, *Pteris serrulata*; 3, *Nepeta Glechoma variegata*; 4, *Carex japonica variegata*; 5, *Ficus repens variegata*.—*A. Wilson.* *Magnolia acuminata*. The flowers will not improve in colour.—*E. S. W.* Probably *Hymenocallis littoralis*; specimen too poor to determine with certainty.

PEACH LEAVES DISEASED: *A. J. B.* Your trees are attacked with the shot-hole fungus, *Cercospora circumscissa*, and should be sprayed with the ammoniacal solution of copper carbonate about every fourteen days. The recipe for carbonate of copper solution is as follows:—Mix the carbonate of copper, 1 oz., and carbonate of ammonia, 5 ozs., in a quart of hot water, and when quite dissolved add 16 quarts of cold water. The solution may be applied to quite young Peach leaves, as it will not harm them, as would the Bordeaux mixture.

ROSE: *T. Adams.* The Rose has no special merit. If it is a seedling, insert cuttings in September, and when rooted plant in good soil. You would then be able to judge better of its value.

SCUM ON PONDS: *A. P.* The green or brown scum on ponds is chiefly due to the smaller algae, and for their destruction use copper sulphate. If there are no fish in the pond apply 1 lb. of copper sulphate to each 100,000 gallons of water. Ordinary commercial copper sulphate is effective, and should be distributed rapidly and thoroughly throughout the pond. For a small pond, enclose the copper sulphate, broken small, in a bag of loose texture, tie to the end of a pole, and drag backwards and forwards through the water. For a large pond, tow the bag behind a boat, and row to and fro in parallel paths not more than from 10 to 20 feet apart.

SYCOMORE OF SCRIPTURE: *V. H. L.* The Sycamore referred to in the Bible is *Ficus Sycomorus*, a species related to the common Fig, and it has no relation to our Sycamore, which is *Acer Pseudo-platanus*. At one time *Ficus sycomorus* was a common tree in the plains of Egypt and the valleys of Palestine, and according to Professor Balfour in *The Plants of the Bible* it is still cultivated near Cairo. You will find further details in Mr. Leo Grindon's book on *Scripture Botany*. *Ficus sycomorus* has substantial boughs, which spread in every direction, after the manner of our British Oak, and may be very easily climbed.

VINES: *M. A. Willis.* You do not give sufficient particulars, and we doubt the accuracy of your thermometer, which shows a maximum of "76° with sun heat" in a vinery facing due south in Kent during such weather as we have recently experienced. From some cause the soil has become sour, probably from too much water, or it may be due to either an excess of manure or want of aeration. If the border is mulched, take off the mulching material, loosen the top soil as deeply as it can be done without injuring the roots, and give a drenching with water, not quite boiling, but so hot that you cannot bear your hands in it. Then apply a good sprinkling of newly slaked lime, and leave the border exposed to the air till such time as there is an improvement in the colour of the leaves, when, if the weather is still hot and dry, a slight shading of loose, strawy manure may be temporarily applied. The leaves should be shaded from bright sunshine till they partially regain their normal colour.
